ORIGINAL ARTICLES.

THE TREATMENT OF ACUTE LOBAR PNEUMONIA.[1]

BY MORRIS MANGES, M.D.,
OF NEW YORK;
VISITING PHYSICIAN TO THE MOUNT SINAI HOSPITAL.

IN opening the discussion of this topic this evening I would say by word of preface that I will restrict myself to the disease as it occurs in adults, and will confine myself to presenting some of the more important indications rather than a complete survey of the whole field.

We are indebted to Townsend and Coolidge[2] for bringing home a very valuable lesson in the treatment of acute lobar pneumonia. The records of 1000 patients who were consecutively treated for this disease at the Massachusetts General Hospital from 1822 to 1889 were carefully studied; they eliminated all cases which were doubtful, *i. e.*, "where death could be reasonably accounted for, that is to say, all who died who were over fifty years of age, were intemperate, delicate, or had complications." The mortality of the cases remaining after this exclusion was reckoned according to decades and presented in a graphic curve (Chart X., *loc. cit.*, p. 40). The result was almost a straight line, the rate varying between nine and fourteen per cent., showing that in spite of all the changes in treatment ranging from the bleeding, purging, salivation, and blistering of 1822 to the symptomatic treatment of our own time, the death-rate at this hospital was practically unchanged.[3] Surely these statistics ranging over a period of more than sixty years, in which the elements of season, sex, epidemics, etc., have been eliminated, must teach a lesson to the physicians who claim such wonderful results from the treatment of pneumonia on any fixed plan. Let them also consider the results obtained about 1850 by Skoda and Diettl with practically no treatment. There is no escape from the conclusion that at present we are utterly powerless to *directly* influence the course of this disease. Our only hope lies in the development of the antitoxin treatment to give us some specific means of combatting the pneumococcus toxemia, for our present knowledge of the life history of the pneumococcus shows that no drug or method of treatment thus far known can in any way surely influence its action.

Although we are justified in expecting the production of a curative pneumococcus antitoxin, the results thus far obtained by Klemperer, Lara, Bozzolo, De Renzi, Pane,[1] and Washburne, while encouraging, are by no means conclusive. The problem is a very difficult one, for all the experimenters have been very much hampered by the great variability in the virulence of the Fraenkl micrococcus, and the corresponding difference in the virulence of the antitoxins produced in animals. The obstacles which must be surmounted are very similar to those encountered in the manufacture of streptococcus antitoxin. It must also be borne in mind that all pneumonias are not caused by the pneumococcus, but that several other micro-organisms also not infrequently produce it; nor must we forget the important relations of the influenza bacillus in the disease as we now encounter it. An excellent résumé of what has already been accomplished with pneumonia antitoxin and serum has recently been published by A. H. Smith.[2]

In the meantime, how shall we treat our patients with pneumonia? Let it be premised that not every case demands treatment; patients presenting the normal picture of the disease, with a not too severe infection and a proper reaction by the system to the infection require nothing more than observation and proper nursing. When treatment is instituted, let it be remembered that we are not treating the pneumonia, but a patient with pneumonia. Also, that some will die in spite of all treatment, and that not a few perish as the result of it. The difference between the cases seen in the hospital-ward and in private practice is most striking. It would aid many a general practitioner to see patient after patient, some with large areas of consolidation, progress nicely on very simple treatment in the wards. To many the diagnosis, pneumonia, *eo ipso*, seems to demand the immediate exhibition of heroic remedies. Meddlesome relations of the patient are bad; meddlesome

[2] *Trans. Amer. Climatological Association*, p. 22, 1889.

[3] The average mortality-rate of pneumonia from all causes and of all ages is much higher, as is best shown by the death-rate of 233,730 cases collected by Wells, of Chicago, *i. e.*, 18.1 per cent. (*Journal American Med. Assn.*, 1892, quoted by Osler, *Amer. Jour. Med. Sciences*, January, 1897).

[1] At the last Italian Congress of Internal Medicine, October, 1898, there was an extended discussion on Pane's antipneumococcus serum. The results of the experiments of Massalongo and Franchini seem to warrant the conclusion that Pane's serum "appeared to have a direct action on the evolution of the pneumococcus process, hindering its diffusion and aiding the process of resolution" (*Philadelphia Med. Journal*, p. 833, October 29, 1898).

[2] *Amer. Jour. of the Med. Sciences*, p. 377, October, 1898.

nurses are worse; but in pneumonia the worst feature of all is the meddlesome doctor.

When treatment is required it must be directed against the toxemia. Its object is fivefold: (1) To maintain life; (2) to support the heart; (3) to control undue fever; (4) to relieve suffering; (5) to control complications.

I. *To Maintain Life.*—This includes the nursing and diet, which are too familiar to require any details. I wish, however, to emphasize the importance of watching the stomach, for not enough attention is paid to ascertain whether it be unduly distended with gas or improperly digested food; even liquids may be improperly disposed of by the stomach. Routine percussion of the stomach is far more important than routine examination of the lungs. The heart must be spared in every way; let its burdens not be unnecessarily increased by upward displacement from the unduly distended stomach and intestines. All articles of diet which may produce flatulence must be rigidly excluded, and the milk must be adapted to the patient both in quantity and in preparation. Do not overfeed these patients; the disease is a very short one, and the patient's surplus fat and tissues will supply any deficit in the diet. Spare the stomach from undue medication as much as possible, and use the hypodermatic method in preference. Give water freely, either cold, hot, or carbonated (unless the patient is cyanotic), for it allays the thirst, reduces the fever and increases the elimination of toxins by promoting free diuresis. For the latter purpose the combination of a light Moselle wine with an alkaline mineral water is exceedingly useful.

II. *To Support the Heart.*—As well described by Douglas Powell[1] the dangers are three in number: (*a*) Impaired nerve power on the part of the pneumogastric branches of the cardiac plexus; (*b*) impaired nutrition of the hard-working heart-muscle from insufficient or badly aerated blood-supply; (*c*) mechanical tendency to overdistention of the right cavities and to depletion of the left cavities of blood.

The drugs which best meet these indications are strychnin, caffein, and nitroglycerin. Strychnin and nitroglycerin are best given in reliable tablets, the caffein in solutions of the benzoate or salicylate. If the results are not promptly obtained the drugs should all be administered hypodermatically. Nor should we hesitate to use them freely, for the action of each is clean cut, and any overdosage can be recognized very readily. My own experience has convinced me of the value of large doses of strychnin, to which Roosevelt called attention, in tiding a heart through the crisis. For the same purpose we may also resort to the hypodermatic injection of camphor in sweet almond oil. Osler also reports good results from hypodermoclysis. A struggling heart is often aided by an ice-bag over the precordium.

Van Santvoord has very recently published an interesting paper[1] which throws an entirely different light on the subject of heart failure in pneumonia. His views are based upon the important experiments of Romberg, which proved that the cardiac weakness in pneumococcus toxemia is due mainly to a vasomotor paralysis, it being clearly demonstrated that arterial pressure is low as the result of relaxation of the peripheral blood-vessels. This is entirely opposed to the prevailing view that the characteristic pulse in pneumonia is one of high tension. If subsequent observations prove the correctness of these views we should be cautious in the use of nitroglycerin for obvious reasons and should restrict its use to the temporary relief of embarrassment of the right heart.

These experiments may also clear up the question of the use of digitalis in pneumonia, about which so much bitter discussion has been waged. The extreme views of Petresco have not found favor. In answer to the low mortality of 2.06 per cent. reported by him and his school in 825 cases (I believe most of these cases were in soldiers, his statistics being those of the military hospital at Bucharest[2]) I may cite the extremely low mortality of 3.6 per cent. in 40,000 German soldiers. Petresco has certainly demonstrated that the danger from these colossal doses of digitalis (12 grams or 180 grains daily) is small, but according to Reiner[3] they must not be continued more than two days at the utmost. Another explanation of the tolerance for these large doses may be found in the experiments of Brunton and Cash,[4] which clearly show that the action of digitalis is lessened in febrile conditions. A safe guide for the use of this drug is that given by Von Juergensen[5]: "Digitalis is indicated as soon as the pulse rises in frequency and at the same time becomes irregular without any demonstrable cause in patients whose hearts were weak before the attack, or in patients whose hearts have weakened during the course of the disease. The fulness or emptiness of the pulse is important in determining this; if it is still full we can afford to wait a little, especially toward the end of the disease when not infrequently one of the indications of an impending favorable turn is slight irregularity of the pulse."

[5] Aufrecht, *op. cit.*, p. 152.

III. *To Control Hyperpyrexia.*—In considering this indication it should always be borne in mind that temperatures ranging up to 104° F. are as normal a feature of pneumonia as dyspnea and rusty sputum. The view which is now generally accepted is that fevers up to this point are the normal reaction of the organism to the invading pneumococci. That these "normal" fevers are even of service to the patient is well shown in a table published by Douglas Powell,[1] in which he demonstrates that pneumococci grow to perfection at 35° and 37° C. (95° to 98.6° F.) and not at all at 40° to 42° C. (104° to 107.6° F.). He also directs attention to the value of the leucocytosis of fever in removing torpid or inert cocci. But, as in all symptoms of pneumonia, we must individualize, for in some patients a fever of 102° F. may inflict more damage than 105° may in others. The thermometer, then, is not the only gage as to the question of the fever being unduly high; the true guide is the patient's general condition.

The use of large, flat ice-bags is the most convenient method for the reduction of undue fever, two or three being applied to the affected area. They are usually well borne and add not a little to the patient's comfort. The ice-bag, however, is no specific against pneumonia, as Mays would have us believe. Occasionally the prolonged use of ice-bags causes intercostal neuritis, as I have observed in two cases. When the nervous symptoms are very pronounced we should not hesitate to resort to cold baths, using them in the same way and on the same general principles as in typhoid fever. If less heroic measures be preferred prolonged immersion in lukewarm baths (90° F.) may be used instead. The contraindications to cold baths are very extensive consolidation of the lungs, marked adynamia, very rapid breathing, feeble heart-action, and arteriosclerosis. Cold sponging and cold packs are often useful. Baruch recommends moist compresses which envelope the entire chest; their antipyretic effect is not very marked and extensive furunculosis (due to the staphylococcus aureus) was noted in two cases at the Mount Sinai Hospital. The large doses of quinin which formerly found so much favor are now seldom employed. The routine usage of the coal-tar products is now, fortunately, discarded; the occasional use of them in small doses is not objectionable.

IV. *To Relieve Suffering.*—The most striking indication under this head is the relief of the pleuritic stitches and the distressing coughs which wear out the patients and rob them of their much-needed sleep. These are best relieved by the hypodermatic injection of morphin, which may be resorted to as soon as possible without unnecessarily weakening the patient by temporizing with other means. The Paquelin cautery often acts magically in quieting pleuritic irritation; no one who has ever used it will temporize with sinapisms, blisters, leeches, poultices, etc. The ice-bag is also very valuable but does not act as promptly as either of the above. Quite recently I have been using a new drug, heroin (diacetic-acid-ester of morphin), as a sedative for these thoracic symptoms, and, so far as my present experience will allow me to judge, I believe that this drug will be found to be a valuable aid in quieting distressing coughs. It has acted well in some cases which were not relieved by codein. It is given in tablet triturates or powders in doses of $\frac{1}{12}$ to $\frac{1}{6}$ of a grain every four hours.[1]

Sleep is an imperative necessity for the overworked patient with pneumonia; to secure it is one of the most imperative indications in the treatment. The nervous exhaustion of which it is often the first herald, may be prevented by the timely use of hypnotics. Of these morphin and chloral are the best. Chloral, when combined with a cardiac tonic is perfectly safe. Balfour, the veteran clinician of Edinburgh, is most enthusiastic in his praise of it. We may also resort to cold packs or alcohol.

Of the value of oxygen in the relief of dyspnea and cyanosis it is difficult to give a final judgment. The opinion is slowly but surely gaining ground among the great clinicians that oxygen has been much overrated in the treatment of pneumonia. Theoretically its employment seems to be so well founded and its application is so simple, the apparent relief so striking that the universality of its use is not at all strange. But does it really do any good in those cases in which we want its effects most? The primary effects soon wear off in serious cases and the dyspnea and cyanosis increase in spite of its free use. Let the enthusiast for oxygen remember that the lung is just as consolidated immediately after the crisis as it was before it, and yet what a change there is in the patient's breathing. This proves that the dyspnea is not entirely mechanical in origin as is generally thought, but is mainly the result of the pneumococcus toxemia. In tiding the patient over sudden attacks of dyspnea and cyanosis oxygen is most useful.

V. *To Control Complications.*—Of these the most important are pleurisy with effusion, empyema, pericarditis, and endocarditis. The treatment of these conditions in pneumonia differs in no wise from that ordinarily pursued and hence requires no special discussion. However, it may be added that effusions into the chest, either serous or purulent, ought to be

[1] *British Medical Journal*, p. 1150, November 9, 1895.

removed as soon as the amount of fluid becomes large enough to interfere with the lung in any way.

THE RATIONALE OF BALNEO- AND MECHANO-THERAPEUTICS (SCHOTT TREATMENT) IN CHRONIC HEART-DISEASES.

By ALBERT ABRAMS, M.D.,
OF SAN FRANCISCO;
PHYSICIAN IN CHARGE OF THE DEPARTMENT FOR DISEASES OF THE CHEST IN THE SAN FRANCISCO INFIRMARY.

CLINICIANS no longer regard the Schott treatment in the light of an experiment. They concede its value in properly selected cases of myocardial disease. The real point of contention is, How can we account for the immediate effects of the baths and exercise? From the vast amount of literature on the subject, three theories may be formulated, as follows:

1. Exercise increases the flow of blood through the tissues, thus promoting tissue respiration and improved nutrition, the heart, like all other tissues, participating in the vivification. The emptying of the capillaries and accelerated flow through the veins are also of benefit in diminishing the resistance to the contractions of the left ventricle.

2. The immediate effect on the heart is not real, the apparent reduction in its size being caused by an increased overlapping of the lungs.

3. The effect on the heart may be demonstrated ad oculos by means of the fluoroscope.[1] With the aid of the Röntgen-ray, according to Schott, an actual reduction in the size of the heart can be demonstrated.

According to the experimental and clinical observations of the writer, all three theories share in the explanation of the good results following the Schott treatment. The first theory is only general in its application; it practically explains the benefits achieved from massage, without reference to any special disease. The second theory has an element of truth. That the lungs dilate after the baths and exercise is unquestionably true, a fact which any one reasonably skilled in physical diagnosis may demonstrate. The only question is, Is the lung dilatation really dependent on the baths and exercise? This question may be answered in the negative, as the following facts will tend to prove: In a recent contribution, Moccucci,[2] at the suggestion of Professor Raimond, sprayed the left half of the abdomen with ether in twelve cases of enlarged spleen. Marked reduction in volume of the spleen was observed in all the cases. In repeating the experiments, the writer likewise noted a decided diminution in the area of splenic dulness in all individuals on whom the method was tried, irrespective of the fact whether enlargement of the spleen existed or not. Was this reduction of splenic dulness real or apparent? If apparent, to what was the reduction due? The reduction of splenic dulness was both apparent and real, but especially did the former prevail. If a spray of ether is directed over the region of the spleen, percussion of that organ shows a diminished area of dulness amounting in most instances to obliteration of the percussional area of dulness. Coincident with this phenomenon, one may note superresonance of the lungs contiguous to the spleen. It is the latter phenomenon which explains the apparent reduction in volume of the spleen. If the spleen is examined by aid of the fluoroscope during the application of the ether spray, a slight reduction in its volume may be observed, but it is in no wise commensurate with the reduction ascertained by linear percussion. Therefore, one is justified in concluding that the splenic reduction is more apparent than real, and consequently another explanation must be sought for the diminished area of splenic dulness.

That the cause is resident in the lungs, simple experiments will show. If the ether spray is directed over the heart region the percussional area of that organ will be reduced at once; in fact, the superficial area of cardiac dulness may be obliterated by this maneuver. Similarly, if the spray is directed over the liver region the superficial area of dulness of that organ can be reduced at once. If the spray is directed over the borders of the lungs posteriorly, the lung borders will descend from two to four inches, dependent on conditions which will engage our attention in another communication. Suffice it to say at this time that dislocation of the lung borders by forced inspiration never approaches the dilatation produced by the ether spray. Further experiments demonstrated in brief the fact that the application of any cutaneous irritant, whether the latter be mechanic, chemic, or electric, will always induce acute dilatation of the lungs. Even in emphysematous individuals the application of a cutaneous irritant will still further augment the existent lung dilatation. Acute lung dilatation is a well established condition occurring in capillary bronchitis and in bronchial asthma. Unlike alveolar emphysema, the alveolar ectasia is temporary and capable of eradication when the cause is removed. The writer has shown[1] that acute dilatation of the lungs can be invoked in healthy persons by irritation of the nasal mucosa. The question naturally arises, By what means are we able to establish the fact that

[1] *Medical Record*, March 26, 1898. *Deutsche medicin. Wochenschrift*, No. 14, 1897.
[2] *Riforma Med.*, p. 208, 1898.

[1] *New York Medical Journal*, June 13, 1896.

the application of any cutaneous irritant will cause acute dilatation of the lungs, a condition, it may be mentioned parenthetically, which is of only a few minutes' duration? In making such a hypothesis tenable we summon to our aid the conventional physical signs and the fluoroscope. These aids show that when the skin is irritated by means of cold, by friction, or by a strong faradic current lung dilatation will ensue. The degree of lung dilatation is dependent on the character of the irritant and the severity of its application. The response of the lung to dilatation is always greatest in that part of the lung contiguous to the source of cutaneous irritation.

The physical signs that enable one to recognize lung dilatation are: (1) Diminished respiratory excursions of the lung borders. (2) Extension of the pulmonary percussion-note and obliteration of the cardiac and splenic areas of dulness. (3) Hyperresonance of the lungs. (4) Absence of the apex beat. The fluoroscope is another valuable aid. Auscultation is most untrustworthy as a sign, insomuch as the artificial lung dilatation is of very short duration, not lasting in the majority of instances longer than three minutes after the source of cutaneous irritation has been done away with. Lung dilatation, it must be observed, does not involve both lungs, nor even an entire lung; it spreads from the source of cutaneous irritation, involving primarily circumscribed parts; then if the irritation is severe enough, more remote parts may be involved. In lung showing diminished resonance, the latter can always be increased by rubbing the skin vigorously over the lung percussed. The writer has learned to rely on this sign, which he calls the *lung reflex*, in all doubtful cases of lung dulness, and to test the resiliency of the pulmonary tissue. He has recently directed attention to this phenomenon in the study of pulmonary atelectasis by means of the Röntgen-ray.[1]

Admitting that lung dilatation ensues by the massage and the baths of the Schott method of treatment, the query naturally arises, Does the lung dilatation effect any reduction in the volume of the heart? This must be answered in the negative. Physiologic experiments demonstrate conclusively that the cavities of the heart are filled with the largest amount of blood during the height of inspiration, consequently the area occupied by the heart is greatest during this phase of respiration. The fluoroscope also demonstrates this fact. There is one fact which must be borne in mind, and that is, that a dilated lung is an excellent depletory channel for a heart surcharged with blood, and that if one is desirous of phlebotomizing a patient to aid an overtaxed heart, the purpose can in a measure be accomplished by securing lung dilatation. In this way lung dilatation helps to secure the results achieved by the Schott treatment.

The third theory, so emphatically espoused by the originator of the Schott method, is undoubtedly correct. The demonstrations of Schott[1] convey conviction to the mind of the impartial reader. Do the baths and massage, according to the Schott method, cause this reduction in the size of the heart? The writer answers this query in the negative. He believes that cutaneous irritation, the result of the resistance movements and the baths, can account alone for the reduction in the area of heart dulness. True, lung dilatation following exercise and the baths will diminish the superficial area of cardiac dulness, but the writer has found that lung dilatation lasts only a few minutes, the lungs after this period receding to their original position, yet the diminished area of cardiac dulness persists. Therefore, one is constrained to admit that the myocardium is responsive to the Schott treatment irrespective of any other factor beyond reflex contraction of a muscle following peripheral stimulation of the cutaneous sensory nerves. In children, less often in adults, one may demonstrate by means of the fluoroscope the great contractility of the heart upon the application of a cutaneous irritant to the precardial region. The irritant employed by the writer in his experiments has been a spray of rhigolen. In one instance, the case of a child with a normal heart, the left ventricle was made to recede almost an inch and a half upon application of the spray. The writer does not deny that systematic resistant movement may influence the heart reflex, perhaps even more so than cutaneous irritation alone. What he wishes to prove is the fact that the sensory nerves of the skin are in a great degree responsible for the good effects observed after the Schott treatment.

The writer employs in many of his patients vigorous cutaneous frictions, in lieu of the conventional Schott treatment, with results nearly as good as by the latter method. Relief of dyspnea follows, and there is a marked reduction of the pulse-rate, together with an increase in volume and force.

The following conclusions may be formulated:

1. Lung dilatation follows the exercise and bath treatment of the Schott method, the dilated lung acting as an excretory channel for the overburdened heart.

2. The cause of the lung dilatation is dependent on cutaneous irritation provoked by the exercise and baths.

3. The degree of lung dilatation may be increased by more powerful cutaneous irritation.

[1] *Philadelphia Medical Journal*, November 26, 1898.

[1] *Medical Record*, March 26, 1898.

4. A decrease in the volume of the heart likewise ensues after the Schott treatment.

5. This reduction in cardiac volume is likewise provoked by cutaneous irritation, which is one of the real factors involved in the Schott treatment.

6. Vigorous cutaneous friction by means of a wire brush, such as is employed in the application of the faradic current, will accomplish almost as much as the baths and exercise of the Schott treatment. At the same time, it is a simpler and more expeditious as well as inexpensive method of treatment.

NEURONS; THEIR RELATIONS TO THERAPEUTICS, MEDICAL AND MECHANICAL.

BY DOUGLAS GRAHAM, M.D.,
OF BOSTON, MASS.

THE minute anatomy of the nervous system has been so carefully studied of late years, and the theory of its functions has changed so rapidly that but few of us older fellows have been able to alter the views that were so positively taught twenty-five years ago. And, indeed, among modern students of the nervous system, its nomenclature, structure, and functions are not by any means uniform, indicating either difference of opinion or carelessness of study.

For our present purpose it will be sufficient to recall a few of the recent and most generally accepted investigations in this field. The neuron consists of the nerve-cell and its branches; the latter are one or two axis cylinders, called neuraxons, and from these proceed side branches called collaterals, which end in tufts of fibrils called terminal arborizations. These terminals communicate with the shorter and more numerous processes of the cell, the dendrites or dendrons, so called for their tree-like appearance.[1] The axis cylinders and their collaterals form the nerve-fibers, and their function seems to be to convey impulses from their cells through their terminal arborizations to the dendrites of other cells which receive the impressions. For a long time physiologists firmly believed or taught that the processes of nerve-cells acted by *continuity*, but more recent researches indicate that they act by *contiguity*, and not by continuity at all. But it is difficult to conceive how this can be unless the nerve-cells and their processes are surrounded by a fluid medium. The neuroglia-cells form an insulating material between the nerve-cells, and must either be active or passive when the neurons are in contact or not in contact. According to the most authoritative histologists, the neuroglia-cells are passive, but a very distinguished one, a Spaniard—Ramon y Cajal—is of the opinion that the neuroglia-cells are the active agents, and that when they are relaxed their processes penetrate between the dendrites and terminal arborizations of the nerve-cells, and hinder the transmission of nerve-currents. When the processes of the neurolgia-cells are retracted, then the nerve-cell projections are allowed to come into contact. The neuroglia-cell processes have numerous short arborescent collaterals, and Cajal thinks he has observed two phases of them: one, that of contraction when the cell-body augments, while the processes shorten and the branches disappear; the other, that of relaxation when the processes of the neuroglia-cells are elongated. Hence, it might appear that the movement on the part of neurons is a passive one, depending upon the interposition of the insulating material. It is more than likely that the activity of the neuron has been mistaken for that of the neuroglia.

Be that as it may, it seems to be now pretty unanimously conceded that nerve-cells and their processes (neurons) are distinct and separate from each other, and, therefore, the theory that they somehow act upon each other by contiguity and not by continuity would seem to have some foundation in fact. In health, when free from fatigue, these nerve-cell projections are supposed to come into contact with each other and form various combinations of thought and action, and the machinery of life goes on when the cog-wheels connect, so to speak. Having reached the limits of fatigue, their terminal arborizations and dendrites no longer come in contact by interlocking, overlapping, or however it may be, but recede from each other, and we have in the brain sleep, in the muscles relaxation, until rest brings them back to a normal condition, renews their waste products, and supplies them with nourishment, when they are again ready to respond by contact to appropriate stimuli. When we have disturbance, functional or organic, then the proper combinations of cells no longer connect for the performance of healthy, voluntary, or involuntary functions.

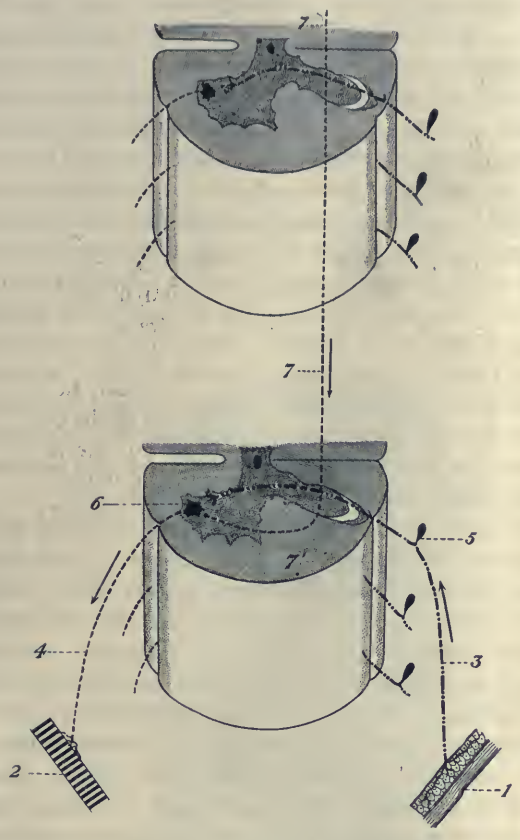
Hypnotism has been invoked to throw light upon this interesting subject.[1] The state of lethargy and

[1] All of the recent medical dictionaries, with the single exception of Lippincott's, either give no definition at all of the new neuron, or else they refer to something else. Thus, "Foster's Encyclopædic Dictionary" for 1894 defines neuron in these words: "In the arthropods, the nervous part of the eye." Gould's, of 1894 and 1898, says neuron is "the cerebro-spinal cord taken as a whole"; also, "a vein or costa of an insect's wing." Dunglison's Dictionary of 1895 does not condescend to notice the meaning of the word; neither does Billings' of 1890. Neither does Clarkson's Histology of 1896 nor Foster's Physiology of 1896 mention the neurons. The American Text-Book of Physiology of 1896 calls the neuraxon the neuron in these words: "From most cells there arises one principal branch . . . called a neuron," thus differing from the classification of Waldeyer, which is now the most recognized.

[1] Dercum, *American Journal of the Medical Sciences*, August, 1896.

relaxation induced thereby would be explained by the retraction of the neurons in the brain so that their terminals do not connect or articulate with the dendrites of the neurons in the spinal cord. Cata-

FIG. 1.



PLAN OF VOLUNTARY MOVEMENT.

1, sensation surface. 2, striated muscular fiber. 3, sensitive nerve-fiber (centripetal) terminating by an arborization around a motor cell and its dendrites. 4, motor nerve-fiber (centrifugal) terminating on the muscular fiber by an arborization (terminal plate). 5, cell of the spinal ganglion constituting with its two prolongations the peripheral sensitive neuron. 6, cell of the anterior nerve with its protoplasmic prolongations and nerve-fiber constituting the peripheral motor neuron. 7, a pyramidal fiber descending from the central cortex, and bending at 7' so as to terminate by a free arborization around the motor cell.—(From Testut's "Anatomy," p. 23, 1897.)

lepsy would then be due to too close contact of the same, manifesting itself by an increase of muscular tone; somnambulism by the combination of certain neurons, whilst others are retracted in sleep, and the sudden disappearance of hysterical paralysis by a removal of contact of the various nerve-cell combinations at fault.

The behavior of nerve-cells and their processes, theoretically, at least, would seem to be similar to that of the white blood-corpuscles in their peculiar ameboid properties. Under the microscope leucocytes anesthetized by the absence of oxygen and the presence of carbonic acid would seem to have their pseudopods retracted. This is thought to form a basis for the histologic theory of sleep, the prolongations of the nerve cells being retracted during sleep and expanding when awake, in dreams some being partially or wholly connected, whilst others that go to make up the conscious *ego* are still contracted in slumber. When we are profoundly absorbed in abstract thought we do not hear the ordinary sounds around us, for certain of our cerebral cells seem to have the faculty of breaking their communications, of somehow closing the door to obtrusive sensations.

Wiedersheim[1] observed in the *Leptodera hyalina* (a species of worm belonging to the nematods) that the nerve-cells were not immovable, but presented changes of form—ameboid-like movements. He studied the living neurons in the brain of this little animal which has so transparent a skin and body that the cells of its brain can be observed while in full activity. These cells seemed to be endowed with a wonderful degree of mobility, changing their forms, protruding their ramifications, and drawing them in, as the ameba protrudes and draws in its pseudopods. The peripheral prolongations of the olfactory cells are pretty surely known to be endowed with motion, and these are quite homologous to the prolongations of the protoplasm of the neuron.

By far the most interesting, satisfactory, and conclusive evidence in favor of this captivating theory that nerve-cells and their projections act by contiguity and not continuity is that of Professor C. F. Hodge of Clark University, Worcester, Mass. His experiments and observations, entitled "A Microscopical Study of Changes Due to Functional Activity in Nerve-Cells," are given in detail in the *Journal of Morphology* for November, 1892. It is one of *the* articles of the Nineteenth Century, and as the journal in which it is published is accessible to but few readers, the methods and results are here reproduced at a length that is more worthy of them than the brief manner in which they have hitherto been referred to. The spinal-root ganglia were chosen for observation. The plan was to stimulate a nerve going to one or more of these ganglia on one side of the animal leaving the corresponding ganglia on the side at rest for comparison. The right side was always chosen for stimulation. The stimulated nerve was never divided so that the contraction of the muscle could indicate the healthy condition of the nerve. At the end of the desired length of time, the stimulated ganglion with its mate on the other side were excised, treated alike, and put on the same slide of the microscope. The following results are from fifteen experiments on frogs and eleven on cats. As the most instructive series is in Table IX, it will be first presented. The experiments were

[1] *Anatomischer Anzeiger*, 1890.

on six cats, in which the right brachial plexus of each was stimulated by an electric current for five hours, fifteen seconds each minute. At the end of five hours the shrinkage of the nuclei was found to be 48.8 per cent. It required fully twenty-four hours of rest for the cells and nuclei to resume their natural size and appearance. The fatigue caused the interstitial substance of the cell to disappear, as shown by vacuoles and lighter granulation, while the nucleus collapsed bodily.

TABLE I.—This showed that stimulation of two and one-half hours, intervals of rest and stimulation being two minutes each, produced a shrinkage of the nuclei of twenty-four per cent.

TABLE III.—Stimulation of three and one-half hours, five stimuli every second, one minute of stimulation alternating with one minute of rest, to sciatic ganglia of right side, caused a shrinkage of thirty-six per cent.

TABLE V.—Stimulation of seven-hours' duration, at intervals of one minute, in a cat caused an average shrinkage of 28.6 per cent.

To show how very carefully these observations were conducted, one hundred cells with their nuclei were measured and their mean diameter ascertained. As a result of fatigue from electrical stimulation there was seen marked decrease in the size of the nucleus, with change from a smooth and rounded outline to a jagged and irregular outline; loss of open reticular appearance, with darker stain. The cell protoplasm showed slight shrinkage in size, vacuolation, and lessened power to stain. The cell-capsule was decreased in size.

The processes of recovery were the reverse of those of fatigue. The protoplasm seemed to recover rapidly, for at the end of six and one-half hours little or no vacuolation could be seen. The nuclei, on the other hand, recovered slowly, not being entirely completed in twenty-four hours.

The effects of normal daily fatigue on sparrows and swallows were also most carefully studied in the same article by Professor Hodge. The nerve-cells of rested birds in the morning were compared with nerve-cells of birds of the same size in the evening after they had been flying about all day. The examinations of the specimens showed a great amount of change after a day's exercise. It exceeded that obtained by artificial stimulation. The greatest per cent. of shrinkage of nuclei, 69.7 per cent., was found in the occipital cortex of a female sparrow that had been working hard all day building her nest. (What could be more interesting?) The spinal ganglion cells of the same bird showed the next highest per cent. of shrinkage, 64.5, as an index of the amount of fatigue. The recuperation from a night's rest must be very great, and in all probability makes up this waste of nerve-cell tissue.

One of his experiments is so full of interest that I give it here in his own words: "On the morning of February 17th it began to rain, and continued nearly the whole day a steady, warm, foggy, spring rain. In the dense cover of the pine-trees over my window the sparrows spent the day scolding and chattering at a great rate. None was observed flying about. At first I decided to abandon the experiment, thinking I should find little evidence of fatigue on such a day. On second thought, however, I concluded to make a rainy-day experiment of it, and see what might be the result. I little expected the sharp and somewhat amusing result expressed in the table. Not an observable sign of fatigue was to be seen in the spinal ganglia, while traces of fatigue were slight in the cells of Purkinje (second layer of cells in the cerebellum). Perfectly clear, however, were the marks of fatigue in the nuclei of the cerebral cortex, as though while confined by the rain the little birds had kept up a deal of thinking."

In order to show how clearly and naturally this original investigator thinks and studies, I will here bring forward some of his own remarks about swallows: "Perhaps the most active bird that we have is the swallow. Quick, vigorous, powerful, careful in all its actions, it must require an enormous amount of nervous energy to coordinate its countless movements for a long summer day. There is nothing lazy nor stupid about the swallow. When their work is done they play games and fly races, and with all the energy required for flying they still have enough left to do no end of talking, for their cheerful *zwitchern* is continually in my ears while I write. At one hundred miles an hour for ten hours, and I have observed them as early as five o'clock in the morning and as late as eight in the evening, a swallow might cover a distance of 1000 miles in a single day. If a bullet of the same might were to traverse the same distance at the same speed, an enormous explosion of energy would be required, and the living arrow can require no less.

"At five o'clock in the morning a large male sparrow was shot, and within five minutes his brain and spinal ganglia were in their proper hardening fluids. A few minutes before eight in the evening another male swallow was taken down, and by eight his brain and spinal ganglia were treated like those of his brother in the morning. Signs of fatigue were everywhere present in the parts examined, but the brains gave the most agreeable surprise. The cerebellum showed the highest per cent. of loss, nearly ten per cent. more than the cerebral cortex. To the cerebellum is ascribed the work of coordination,

and where could be sought an instance of more delicate manipulation than must be required to drive the wing of a swallow as it flits and whirls and balances and wheels and darts the whole day long?''

The brains of honey-bees were also compared, and it was found that those that had been at work all day showed a shrinkage in their cells of from nine to seventy-five per cent. as compared with the brains of similar bees in the morning. Great is the recuperation from fatigue of honey-bees. The food they gather must be very nourishing and sustaining.

That celebrated poison, *woorara*, which the South-American Indians use to poision their arrows with, when injected into the human system has long been known to cause paralysis of the terminal branches and peripheral plates of the motor nerves (peripheral neurons, we must now say), so that the nerve-force no longer connects in such a way as to produce muscular contraction. This poison, according to the experiments of Hammond and Weir Mitchell, seems to act directly upon the heart, probably through the ganglia in its tissue, as well as upon the voluntary muscles. It also destroys the reflex functions of the spinal cord. Strychnin, on the other hand, is equally well known to increase the excitability of the nerve-cells in the spinal cord, manifesting itself in muscular spasm when taken in poisonous doses. In the case of woorara, it might be said that the protoplasmic processes of the nerve-cells can no longer come in contact with the projections of other nerve-cells; in the case of strychnin, that they are in too close contact and cannot let go. It is not improbable that the action of all medicines, and the different effects of the same medicine when taken in small or large doses, may be partly explained in this way by their producing an ultimate chemico-mechanical effect on the nerve-cells in different parts of the body. It is also supposable that the action of different poisons on the nervous system, whether generated in the body itself or introduced from outside may, in great part, be explained in the same way. Thus before long we may have a new system of therapeutics based on a new system of neuropathology.

FIG. 2.

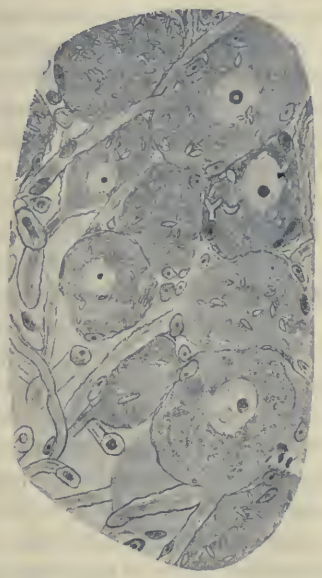


FIG. 3.

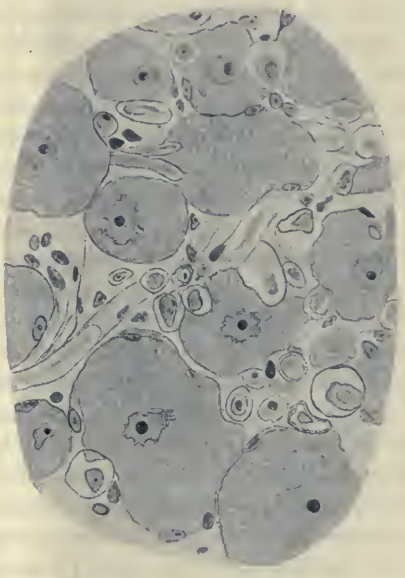

FIGURE 2.—Portion of field from third brachial plexus of an English sparrow, killed December, 1891, at 7 A.M. Osmic acid 1 per cent.; two hours.

FIGURE 3.—Field of corresponding ganglion of English sparrow killed the same day at 7:30 P.M. Like preparation with Figure 2.

These fields demonstrate extreme daily fatigue with probably some lack of food. The queer-shaped clear spaces in Figure 2 are seen to be replaced to a great degree in Figure 3 by faulty outlined irregular vacuoles. Nuclei in Figure 3 appear shrunken as in cases of electrical stimulation.—(Hodge, *Journal of Morphology*, vol. vii, p. 168, 1892.)

We have all felt the lassitude of extreme fatigue, which might now be explained by saying that it is due in great measure to shrivelling of the nerve-cells, preventing contact of their projections, and most of us when young have probably suffered from cramp in our calves after a hard-day's tramp, which, according to this theory, would be due to the nerve-cell processes, the terminal arborizations and the dendrites having got too closely interlocked from the irritation of waste products, showing itself in muscular spasm. That we may have from retained waste products of excessive exertion, both relaxation and cramps, is not without its analogy in poison introduced into the system from without. Lead, for in-

stance, causes paralysis and relaxation of the extensors of the hands, while in the abdomen it often induces spasms, cramps, and colic. From experiments in animals, Dr. Earnest Harneck[1] concluded that lead colic is due to intense excitation of the intestinal ganglia by the lead, producing arrest of peristalsis from spasm of the muscular coat. Shall we say that the neurons that preside over the nerves, that move the extensors have their protoplasmic processes immovably retracted so that they can no longer vibrate and articulate, while those that control the intestines and abdominal walls are in too close connection, spasmodically interlocked, or anchylosed?[2] However this may be, strychnin is one of the remedies relied upon for the paralysis of lead after its elimination by other remedies, and perhaps it acts by bringing the neurons into better condition for normal contact. A new explanation may thus be afforded for the action of excitomotor remedies, such as strychnin, ergot, digitalis, etc.; and also, though just the opposite for depressomotors, such as the bromids, chloral, gelsemium, conium, etc. The action of other remedial agents, internal and external, might be explained more or less in the same way.

Tea and coffee are said to stimulate the ameboid movements of protoplasm. At times they certainly aid in stimulating thought and in forming new combinations of ideas, perhaps by bringing about different relationships of the cortical neurons. Tobacco, on the other hand, by its sedative and relaxing properties seems to suit some students better in the collection of their thoughts, which, according to this theory, would be by causing relaxation of cortical neurons that had been too much preoccupied in loving embrace or close combat, and thus allowing others to form new combinations.

The effects of tonics, stimulants, and sedatives, whether of a chemical or mechanical, electrical, thermal, or dynamical nature, upon central and peripheral neurons are probably similar, simultaneous and parallel to what they are upon voluntary and involuntary muscular fibers. Hence the state of the muscles is very likely a good barometer of what is going on at the other ends of the nerves that supply them in brain or spinal cord. Every muscle-reader is a mind-reader, and he who has the *tactus eruditus* well developed, be he a physician or a masseur, has an immense advantage in the diagnosis and treatment of neuromuscular troubles. In two cases of hemiplegia recently under my observation there was much spasm (contracture) of the flexors of the hand and arm. The patients were both receiving the faradic current, which is well known to stimulate muscular contraction, and were taking strychnin internally. As soon as the faradism was stopped the spasm became less; and later when the strychnin was left off there was still greater improvement; the contracture almost entirely disappeared, allowing the opposing paralyzed extensors to come into play as much as they could. In these cases the effects of the strychnin and faradism might have been, and probably were, simultaneous upon central and peripheral neurons, terminal arborizations, and muscular fibers.

The effect of stimulation upon protoplasm is, when sufficiently strong, to cause an immediate cessation of movements and withdrawal of protruded processes into the main substance. Upon cessation of the stimulation, if it has not been too strong, the movements will begin again, but if so severe as to injure the living substance they stop forever. Mechanical stimuli and abrupt changes of temperature act in like manner. It is quite conceivable that nerve cells and their projections behave in the same way.

Recent experimental studies tend to strengthen the theory that neurons act by contiguity and not by continuity. After slight injury to the head and spinal column Lutzenberger studied the changes in the nervous system of guinea-pigs and found that the general disorders of nutrition showed themselves most prominently in the increase of the number of ganglion-cells that presented all styles of retrogression.[1] Parascondola has also made an extensive study of the effects of shock upon guinea-pigs. He stretched them out flat and gave them a sharp blow upon the abdomen with a flat ruler. The animals reacted in various ways. Most of them after a period of quiet seemed to recover; but in from thirty-six to forty-eight hours they died with symptoms of exhaustion or shock. The cerebrum, cerebellum, medulla, and spinal cord were removed for microscopic examination. The alterations found were deformities of the cell bodies to the extent of actual atrophy, node-like swellings on the dendrites and fragmentation of the same. There was also found degeneration of the posterior roots, proceeding even to degeneration of the posterior columns. Changes in the cellular protoplasm were also seen—rarefaction proceeding to vacuolation in the nucleus, and vesicular swelling of the nuclear protoplasm.[2]

[1] Biddle's, "Materia Medica."

[2] Dr. T. Lauder Brunton tells us that one of the most painful experiences of his life was that of being nearly tickled to death by a nurse when he was a small boy. He can never forget the agony of it. This leads him to believe the statement that Simon de Montfort, during the persecution of the Albigenses, put some of them to death by tickling the soles of their feet with a feather. The neurons may have become so tightly interlocked that they could not let go. Perhaps something of the same kind occurs in tetanus.

[1] *Annali di Neuroglia*, 1897.

[2] *Archives de Physiologie normale et physiologique*, 1898.

These were very serious alterations and all tend to throw light upon the nature of fatigue, shock, neurasthenia and hysteria arising from injury. But percussion, though harmful in large doses, is often beneficial in small ones, stimulating languid nerves and muscles, and sometimes relieving painful ones by over-inciting them and wearing out their irritability, and presumably at the same time favorably influencing the vibrations and connections of nerve-terminals and dendritic processes.

It seems rather curious that those who have furnished the clearest objective evidence that nerve-cells and their projections act upon each other by contiguity and not by continuity are not the ones that have advanced this theory at all. Thus Professor Hodge in the *Journal of Morphology* for 1892, the New York *Medical Record*, March 26, 1898, and in previous publications says nothing of this theory, and yet he has furnished the clearest objective evidence of it. Credit is given to two Frenchmen, one, M. Lépine, for having first advanced this theory in the *Revue de médicine* in 1894, and the other, M. Mathias Duval, for agreeing with him in the *Comptes rendus de la societé de biologie*, 1895. These gentlemen must have exceedingly brilliant imaginations, for they scarcely ever refer to the labors of others, and not at all to those of Professor Hodge, that would furnish them with objective evidence confirmatory of their theory. This seems to be always a rapid way of becoming famous. Their hypothesis seems to have been evolved from a single case of hysteria of a peculiar kind that suddenly passed from complete deafness to acute hearing, and which they explained by saying that "the anesthesias, sensitive and sensorial, and the motor paralysis in the hysterical are due to imperfect contact between the ramifications of the nerve-cells"; or the disappearance of these morbid states is owing "to an erethism of the prolongations of the nerve-cells, by which they are brought into normal contact, attention sufficing to reestablish the contacts."

When distinguished gentleman like these are allowed to hold this theory on such insufficient evidence and with so little regard to the testimony of others, it behooves us to ask if this theory or something like it has not been promulgated before, for it has given these Frenchmen great renown, and neurologists are disposed to believe in it. William H. Munroe of Boston was a very intelligent layman who had studied anatomy and physiology to a moderate extent. He died in 1887, at the age of eighty years. For the last thirty years of his life he was firmly and enthusiastically of the opinion that somehow or other in disease the nerves did not connect properly, and "to remedy this evil" (as he used to say), and to make them connect he relied on manipulation by hand, a mode of treatment in which he became very skilful, and which, viewed from a recent light, he not altogether inappropriately called the nervous-adjustment cure. He had a large clientele of intelligent people, most of whom were fascinated with his theory, while physicians smiled incredulously at the theory and the seeming irregularity of the practice. An association with him for three years, before I studied medicine, from 1867 to 1870, convinced me of the efficacy of this treatment in disturbances of nerves, muscles, and joints, mostly of a chronic nature. From observations of massage in this country and abroad, extending over thirty years, I may, perhaps, be allowed to say that he certainly had the best single method of this art that I have yet met with. Wherever there was undue tension of the tissues, there the nerves were supposed to fail in properly connecting, and the thorough, agreeable, and efficacious manipulation of the offending region often proved beneficial; and even when it failed to do good, it left behind it a pleasant impressson far different from that after the scraping, greasing, or slapping that too often passes for massage. Indeed, the word massage is becoming subject to so much abuse that, perhaps, such an expression as manipulation or manual treatment had better be adopted in place of it, for more depends on the skill and experience of the manipulator and his understanding of the disorders, than in the use of any "highfalutin" words to cover ordinary rubbing.

From the days of Hippocrates, history affords parallel examples of theories formed in advance of their proof. For our present purpose we will cite but one, that of Asclepiades (128–56 B. C.), a Greek physician, who founded a school and practised at Rome, and was very popular with the Romans on account of his simple and agreeable remedies. He thought that physicians ought to cure their patients safely, quickly, and pleasantly, and with this object in view he relied mainly on diet, bathing, exercise, and friction. He considered that the body had innumerable sensitive canals running through it, in which moved the nutritive juices and plastic atoms. So long as this movement went on without disturbance, health continued. But disturbance caused sickness, and the normal movement of these juices would be disturbed by abnormal increase of their atoms, by their irregular distribution, by too great blending together, and by too swift movement of the same, and also by dilatation and constriction of their canals. Proceeding on these principles, or theories, rather, Asclepiades renounced almost entirely the use of medicines, and

attempted to restore free movement of the nutritive fluids and plastic atoms by means of rubbing. The soporific effects of gentle stroking he also recognized. With friction he combined active and passive motion, and no doubt but he was an adept at massage in his day.

Asclepiades thus foreshadowed the discoveries made long after of the functions of the vasomotor nerves and of the muscular coat of the blood-vessels in regulating the caliber of these vessels; and to a large extent, also, he predicted the pathology of inflammation in the congregating of white blood-corpucles.

Seen from the light of recent studies of the neuron, the experiments of Professor Golz of Strassburg, narrated in *Virchow's Archives* for 1875, possessed new interest. After opening the abdomens of animals and applying percussion by light and frequent blows over the stomach and intestines, the peritoneum at first became paler from constriction of the vessels, but continuance of the percussion caused dilatation. When the percussion was first applied over the abdominal walls, and these opened afterward, it was seen that the vessels of the abdominal cavity, especially the veins, were dilated and distended with blood. The heart's action was considerably retarded, owing to the reflex influence of the percussion upon the inhibitory action of the vagus, and also to the sudden withdrawal of blood into the vessels of the abdomen. Continued still longer, the pulsations of the heart became less, and finally ceased, as did also respiration.

Here we see the primary effects of percussion (a form of massage) causing constriction of blood-vessels from stimulation of their vasomotor nerves and muscular coat. Longer continued, this same percussion produces an opposite effect, dilatation of vessels from over-inciting them, and wearing out their irritability, and with still more of it pulse and respiration cease. Corresponding to the first influence of percussion, we would now suppose that the projections of the neurons had been brought into closer juxtaposition; to the second, that they had got somewhat tired out and relaxed; to the third, that they had lost their capability forever to connect, and the animal dies. It would be exceedingly interesting to examine the neurons connected with the solar plexus of prize-fighters when they knock the wind out of each other by a blow upon the epigastrium.

If this theory of the mechanical action of nerve-cells and their processes holds, then remedial mechanical measures, such as massage, kneading, stroking, percussion, passive and resistive movements, all of which act upon peripheral and central neurons, will receive an additional explanation to what we already know of their effects upon skin and muscles, blood vessels, lymphatics, and nerves. We would then say of a nervous person with too much tension, who cannot let himself go to rest, that under the influence of appropriate manipulation he is soothed and quieted to sleep, that his peripheral and central neurons have been coaxed to relax; while on the other hand, if such a patient should receive too vigorous manipulations the peripheral irritation caused thereby would induce both voluntary and involuntary resistance, increase the tension and bring the processes of the neurons into still closer contact. Or take languid individuals with flabby tissues and give them pretty vigorous manipulation. Their muscles tone up and become firmer; then we will have to presume that their neurons have come into closer and more natural contact. It was old Hippocrates who said in his aphorisms that "Hard rubbing binds; soft rubbing loosens; much rubbing causes parts to waste; moderate rubbing makes them grow."

By means of training and repeated efforts paths of resistance in brain, spinal cord, and nerves are made easier, thought, will, and action become less difficult, and the terminal arborizations of the neuraxons and their collaterals connect more readily with the dendrites of the nerve-cells, constituting what is usually called education, which should be so adjusted

"That outer man and inner soul
"Maintain their balance true
"Till every string on being's lyre
"Gives forth its music due."

On the whole this theory that nerve-cells and their processes act upon each other by contiguity and not by continuity would seem to be consistent with the behavior of tissues in other parts of the body, and even with the propagation, prolongation, and cessation of life itself.

CLINICAL MEMORANDUM.

THE DIAGNOSIS OF TRICHINOSIS BY MEANS OF THE GREAT INCREASE OF THE EOSINOPHILES IN THE BLOOD; REPORT OF THE FOURTH CASE.

By THOMAS R. BROWN, M.D.,
OF BALTIMORE, MD.

In 1897, in reporting the great increase of the eosinophiles in the blood in a case of trichinosis[1] this being the first mention ever made of an association between trichinosis and eosinophilia, I made use of the following words: "The presence of such quantities of eosinophiles in the blood suggests their possible diagnostic value in trichinosis, and perhaps, if it be found on further studies to be characteristic of this disease, may help to clear up the

[1] *Johns Hopkins Hospital Bulletin*, pp. 79-81, April, 1897.

cases which are regarded *intra vitam* as rheumatic in nature and which, years afterward, the autopsy-table shows to have been cases of trichinosis." That the disease is not such a rare one in America as is usually supposed and that it may be definitely diagnosed by the remarkable increase of the eosinophiles in the blood is amply proven by the results obtained since that time.

In 1898 I reported[1] two additional cases wherein, from the eosinophilia alone, the condition of trichinosis was diagnosed, and in all three cases, living, actively motile, non-encapsulated trichinæ were found in small pieces of muscle removed from the patient. The concluding sentences of that article may be of interest in this connection: "From these observations it is fair to conclude:

"1st. That there is a marked increase in the percentage of eosinophilic cells in the blood in trichinosis.

"2d. That the increase may be used as a diagnostic sign in this disease.

"3d. That this diasease in its sporadic form is more common than has hitherto been supposed, as shown by the discovery of the three cases above described within a comparatively short period at the Johns Hopkins Hospital.

4th. That a systematic examination of the blood should be undertaken in cases with indefinite intestinal, muscular or articular symptoms in the hope that in some, at least, of the hitherto doubtful cases a diagnosis may be made."

I have now to report another case of this disease, diagnosed entirely by means of the blood examination, the diagnosis being verified by the subsequent removal of a small piece of muscle and the finding of living, actively motile trichinæ therein.

RESULT OF BLOOD EXAMINATION IN A CASE OF TRICHINOSIS. (J. L., CASE IV.)

'J. L., white, aged thirteen years, was admitted to the Johns Hopkins Hospital, August 4, 1898. He complained of headache and pain in the legs; he had never been sick before. On July 30th he commenced to have headache, which was still present at the time of his admission. On July 31st he had a slight nose-bleed, while during two days, July 30th and 31st, he had had pains in the shins. He had a good appetite, the bowels moved regularly every day, and he had not had chills, nausea, nor vomiting.

The physical examination showed the patient to be a small boy of dull appearance, with eyelids somewhat swollen. His heart and lungs were negative. There was no abdominal tenderness; no rose spots. The spleen was not palpable; tongue thickly coated; considerable gurgling in the right iliac fossa. There was neither swelling nor tenderness in the muscles of the arms or legs; the throat was negative. The temperature range was between 98 and 100.2° F. during the first four days and the case was at first regarded as a mild febricula of doubtful origin, possibly typhoid fever.

On August 10th an examination of a specimen of freshly taken blood was made, and one was at once struck by the large number of eosinophiles present, these cells with their large, highly refractive granulations being unmistakable. A differential count made on dried specimens, stained with the Ehrlich stain, showed that 48 per cent. of all the white blood-cells were eosinophiles, and this *at once* led to a diagnosis of trichinosis being made.

Further questioning of the patient elicited the fact that about one week previous to his admission to the hospital he had had pain in the calf-muscles of both legs, never very great, while there had never been any pain in the other muscles of the body. The legs had never been swollen, but the eyelids had become slightly puffy four days before his entrance. He had not had abdominal pain or diarrhea. On being questioned as to whether he had recently partaken of hog-meat of any kind he remembered having eaten of raw sausage on July 10th, and of cooked ham on July 23d.

On August 11th a small piece of muscle was removed from the left gastrocnemius muscle under cocain anesthesia; this was hardened in formalin, and subsequent microscopic examination showed the same changes as described in full in the preceding three cases (*loc.cit.* p. 328, *et seq.*); the presence of young, non-encapsulated trichinæ in some of the muscle-fibers, about them a fresh, active myositis with many eosinophiles among the cells present, and various degenerate changes in the muscle-fibers themselves, marked swelling and proliferation of the nuclei, longitudinal and transverse splitting of the fibers, etc. The patient's temperature varied between 96.2° and 99.5° F. from the fourth to the twelfth day of his stay, after the twelfth day being practically normal. The urine was negative throughout and the blood did not give the Widal reaction.

[1] *Journal of Experimental Medicine*, vol. iii, No. 3, pp. 315-347.

The patient was discharged from the hospital on August 22d, feeling perfectly well. During his stay in the hospital his blood showed a leucocytosis of 18,100, while upon each of the two occasions on which a differential count of the leucocytes was made, it was found that 48 per cent. were eosinophiles. As in the other cases reported, the nucleus of the eosinophiles was polymorphous, *i.e.*, identical in form with the nucleus of the neutrophiles.

As I thought it would be of considerable interest to determine how long the condition of eosinophilia lasted after the disappearance of all other symptoms of the disease, the patient was persuaded to return on various occasions within the next three months to have his blood examined. Although the number of leucocytes per cubic millimeter diminished rapidly and was practically normal after the last part of August, nevertheless, the decrease in the percentage of eosinophiles was very gradual, and even on November 20th, the date of the last count, more than three months after the complete disappearance of all other symptoms, a slight eosinophilic increase was still present, the normal percentage of eosinophiles being from 1 to 3 per cent. Elsewhere [1] I have shown in the third case reported by me that the blood was normal both as regards number of leucocytes per cubic millimeter and percentage of the various forms five months after the complete cessation of all other symptoms.

Where the eosinophiles come from, in trichinosis, is still undecided, but a study of the blood and muscle in the four cases leads one to the conclusion that they are probably derived from the polymorphonuclear neutrophiles, those cells normally constituting from 65 to 80 per cent. of all the white cells of the blood, and that this transition takes place in the affected muscles. This is supported by the inverse relationship which exists between the eosinophiles and the neutrophiles in the four cases, by the identical character of the nuclei of both forms, *i.e.*, they are both polymorphous and that what are apparently transitional forms between the two were found in the affected portions of the muscle. Thus the addition of this case makes four cases in all in which this association between trichinosis and a very high grade of eosinophilia was present; in the first case, the eosinophiles reached 68.2 per cent. of all the white blood-cells; in the second 42.8 per cent., in the third 49 per cent., and in the fourth 48 per cent., while the total number of leucocytes per cubic millimeter reached 35,000 in the first case, 13,000 in the second, 17,000 in the third, and 18,000 in the fourth.

Just as this article is being brought to a conclusion I learn that a fifth case has just been diagnosed by an eosinophilia in the neighborhood of 50 per cent., with the subsequent verification of this diagnosis by the removal of a small bit of muscle and the finding of the actively motile parasites therein.

Of the four cases I have reported, in only one, the first, was there anything in the clinical history to make one even suspect that the case was one of trichinosis, and it was only by means of the remarkable eosinophilia present, so easily made out by merely glancing at a fresh specimen of the blood under the microscope, that the diagnosis was made. In fact, the second and fourth cases were regarded as probable cases of typhoid and the third as estivo-autumnal malaria before the blood examination was made.

Of course in a few other conditions an eosinophilia is noted in the blood, notably in bronchial asthma during the paroxysm and in splenomyelogenous leucemia, but the eosinophilia in these conditions is of not so high a grade and moreover, the diagnosis is easily reached by means of other signs and symptoms. But in trichinosis, except in the most marked cases or in the epidemic form, a diagnosis is impossible without a blood examination, and in conclusion I would like once more to suggest the great advisability of making the examination in febrile cases of doubtful origin and in cases with indefinite intestinal or muscular symptoms. This examination will require but a few moments and by the demonstration of a marked eosinophilia it may clear up a case now and then which otherwise would go down to posterity as another of that great class of cases, the undiagnosed.

SPECIAL ARTICLE.

THE GARRISONING OF OUR TROPICAL POSSESSIONS.

THE METEOROLOGIC AND TELLURIC CONDITIONS OF CUBA AND PUERTO RICO.

By SENECA EGBERT, M.D.,
OF PHILADELPHIA;
PROFESSOR OF HYGIENE AND DEAN OF THE FACULTY IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

No. 2.

INASMUCH as both Cuba and Puerto Rico lie south of the Tropic of Cancer their climates are naturally considerably warmer and also less subject to extreme variations than that of our own country and latitude. Cuba, which with her adjacent islands has an area almost exactly equal to that of the State of Pennsylvania, lies some ninety odd miles south of the Florida peninsula and the Bahamas, and separates the current which sweeps strongly and westwardly along its northern coast to meet the Gulf Stream from the warm waters of the Caribbean Sea that wash its southern shores. Long and narrow in shape, with rather low mountain ranges forming the main axis, and in the situation described, one could almost certainly predicate the meteorologic conditions of the island without further information. It will be well to mention, however, that although it has a length through the center of about 730 miles, it has an average width of only 80 miles; that the mountain ranges attain their greatest elevation and have their highest peaks in the southeastern portion of the island, and that the rivers which mainly trend either to the north or south, are numerous and, for the most, short and not navigable for extended distances.

Puerto Rico lies more than 500 miles to the eastward and somewhat south of Cuba, and is much smaller than the latter, being only 108 miles long and 37 broad. It also

extends east and west and has a range of low mountains parallel to and somewhat south of the longitudinal axis. The highest peak (3600 feet) is, however, in the northeastern portion of the island. It is evident that the rivers, flowing as they do either to the north or south, cannot be of any great length or size.

Situated as they are, the climate of these islands, like that of the other West Indies, will obviously be of a tropical nature, especially at the sea level; but, as elsewhere, altitude will have its modifying effect. Thus, the early Spanish discoverers made a distinction as to localities, classifying them as the Tierra Calientes (hot lands), Tierra Templada (temperate lands) and the Tierra Fria (cold lands). Along the coast, both north and south, the temperature averages between 70° and 74° F. in the winter months and 82° or 83° F. in summer, the average for the whole year in Havana being about 77° F. Inland and in the hill country at elevations above 300 or 400 feet, the temperature occasionally falls to the freezing point and frosts are not uncommon. The Tierra Templada lie at elevations between 2000 and 4000 feet, and have a climate similar to that of our Southern States, and more temperate than that of the lower levels. The Tierra Fria are practically above the level of 4000 feet, are necessarily limited in extent and have an average temperature and climate warmer than their title would indicate, for it is said that snow is never seen in Cuba. For the western part of this island, cool north winds, coming from the United States and crossing the Gulf Stream, are not uncommon in the dry or winter season.

In the coastal regions, and especially in Eastern Cuba, the annual rainfall is heavy, sometimes aggregating 70 inches. However, the "Encyclopædia Britannica" is authority for the statement that the average for seven consecutive years in Havana was only 40.5 inches, or but little more than the annual average for Philadelphia. More than two-thirds of the rain falls in the wet season, between the first of May and the first of November, and from July until the end of the season thunder showers are of almost daily occurrence. It is said that if the heavy rains are late in coming the heat becomes more oppressive and the conditions favoring epidemic diseases are intensified. The thunder showers usually occur in the late afternoon. After a day of overpowering heat and, probably, of excessive humidity, there is a heavy downpour of rain, accompanied by sharp and vivid thunder and lightning. This may last for two hours or more, when it quickly ceases and evaporation from the overheated and surcharged earth begins and a heavy fog or mist is formed which envelops everything and doubtless carries in it myriads of the miasmatic organisms that infest the soil.

It was partially on account of such conditions that our troops had such a disastrous experience in the recent Santiago campaign. The daily drenchings and subsequent cooling due to the rapid evaporation not only made the men, who had been exposed to the intense and exhausting noon-day heat, extremely uncomfortable throughout the night, but quickly produced the intense chills that so depressed the soldier's constitution and vitality that he became an easy prey to the pathogenic organisms carried by the all-prevading fog, or that most certainly infected the surface- and ground-water that he ignorantly or recklessly drank to quench his thirst in the burning heat of the following day. Small wonder is it that so many succumbed to the malarias, the *calenturas*, and the yellow fever. Rather may we be surprised that any escaped the infection of these maladies. Only the knowledge and wisest application of sanitary laws and measures will serve to protect those who are exposed to such conditions before they are thoroughly acclimated.

Puerto Rico is considered to be cooler and pleasanter in climate than Cuba, but the difference is only one of degree and both islands have their superabundance of rain in the wet season, and especially in their eastern provinces. Here the high and cooler peaks and elevations of these localities stand like sentinels to intercept the warm trade winds, overladen with moisture and continually sweeping in from the Atlantic, and the heavy rainfalls and the marked electrical displays are but the natural physical results of these conditions.

Hurricanes are in reality not so frequent in these islands as is commonly believed since several years sometimes intervene between them. When they do occur it is most likely to be in August, September, or October, when the other atmospheric disturbances are greatest and most common.

The soil of the two islands and their geologic features are quite similar in character. The former is mainly calcareous in nature, with underlying granite and other igneous rocks and, in western Cuba, outcroppings of serpentine and syenitic formations. A marked red or brown tinge shows the presence of iron through most of eastern Cuba, but this disappears toward the center and gives place further westward to the lighter and yellowish color of the prevalent sandstone and gypsum formations.

On account of the warm and equable temperature, and the large amount of moisture, vegetation is luxuriant throughout the greater part of both islands; humus is, therefore, abundant, and the fertility of the soil has long been almost proverbial. Tobacco, sugar-cane, tropical fruits, and trees all thrive in the coastal regions and lower levels, while at moderate altitudes coffee has been and doubtless will be in the future even more profitably cultivated. The opportunity for the successful growth of the various crops of the temperate zone here presents itself, and no one can now estimate Cuba's value alone as a nation's garden.

But from the very nature of things these conditions which are so favorable to commercial agriculture, also foster the almost unlimited development of the causes of many infectious maladies. With the constant heat, moisture, lime and other salts, and the abundance of decaying organic matter, almost any kind of "germs" would have no difficulty in multiplying luxuriantly in the soil, and with the numerous streams and the dismal fogs to carry them thence, the frequent occurrence of the respective diseases is only to be expected. Add to this the depression and increased susceptibility to sickness produced in the unacclimated by excessive and unaccustomed

heat, unsuitable clothing, insufficient or improper food, and bodily fatigue, and nothing but inevitable illness can be expected. However, there is no evidence that Cuba was originally the habitat of any of these pathogenic organisms, excepting possibly those of a malarial nature which are to be found in all tropical countries. In fact, until comparatively recently the interior and especially the elevated portions of the island were remarkably free from any epidemic or endemic diseases, and though no one today can say that any particular locality has not been infected by the sick of the troops of both sides which have been passing and repassing during the last three years, it is entirely possible and probable that with the enforcement of prompt and proper sanitary measures these favored localities can be speedily restored to their pristine salubrity. On the other hand, the conditions are far different along the coast line and especially in the cities where large numbers of people have been neglecting the laws of hygiene for years and where everything that could favor the spread of disease from person to person has had full power and sway.

In the forests and jungles, where the sunlight is veiled from the earth's surface by the riot of vegetation, where the atmospheric humidity is almost if not quite at the saturation-point and where the soil is soaked and dank from the daily showers, the organisms of malaria, of strange fevers, and of the *calenturas*, have the choicest of breeding-places; and whether one believes or not in the ascensional powers of evaporation and that the dense fogs can lift these organisms bodily from the surface of the soil, no one doubts that both the air and the ground-water of such places are full of peril and poison to him who partakes of them. And of what house, hut, or hovel can we be certain that it has not been infected by some yellow-fever or smallpox patient who may have occupied it but for a night or a day? Danger may lurk in all of these, and the warning should be positive and firm that our garrisoning forces may not make use of these isolated or collected shelters that they may find apparently ready to their service throughout the country districts. It has already been shown that the marines at Guantanamo burned the rude and probably infected buildings which they found there, observed sanitary precautions and escaped disease almost absolutely throughout their ten-weeks' stay; while the neighboring army only a few miles distant, under similar climatic conditions, but neglecting hygiene and using like structures for shelter and, after the battles, for hospitals, quickly and extensively developed malaria, yellow fever, and other ills. Making every allowance for the emergencies and difficulties with which the larger body of troops was confronted, and for the impossibility of satisfactorily enforcing rules and regulations theoretically perfect and proper at such a time and under such circumstances, the deductions to be drawn from the above comparison must be plain to all. It is probable that in such crises disaster will always come upon men ignorant of the laws of hygiene, no matter how stringent the rules from headquarters intended to govern their physical welfare; but if they are individually educated and informed as to these matters and know the reason and importance of the respective precautions, then each man becomes a sanitary guard for himself and for all his comrades. In other words, why should not the Army have the same drill and instruction in hygiene and its laws as the Navy and Marine Service, and why might there not be equally good results from such teaching?

Referring finally to the larger Cuban cities where the laws and methods of modern hygiene have been almost unknown and certainly unpractised for many years, the risks of disease are probably even greater than in the forests. Accumulations of filth that have been growing for decades, polluted water-supplies, ignorance of disinfection and its power for good, and a total disregard of the dangers to which one sick with an infectious malady may subject others have worked together to render many of the larger towns and cities veritable hotbeds of disease. The consular reports for last month show a death-rate in Havana for the week ending December 1st equivalent to an annual ratio of 109.8 per thousand, or five times that of Philadelphia or New York, and that that of the City of Cienfuegos is even worse. In these cities fully half the deaths were from infectious diseases more or less readily preventable, and the same official reports show that the municipal and physical conditions are such as to warrant and demand the most vigorous sanitary action *immediately*. Probably the same stories can be told of every other large community in the island, and again making every allowance for the deprivations and demoralization of the recent war we can but admit that disease and pestilence could scarcely have had more freedom and license for destruction in modern times than in these cities under Spanish rule.

But fortunately the conditions are not hopeless and a great opportunity presents itself for a convincing demonstration of the powers of modern sanitation and preventive medicine. We all regret the loss of Colonel Waring, and all appreciate the possibilities that lay in his conduct of affairs in Havana, had he been spared for the work. But in Santiago, where the conditions were as bad, if not worse than those mentioned, General (but also Doctor) Wood has created reforms and made improvements in a few short weeks that seem almost incredible to even those of the strongest faith. The following tribute to his work is worthy of quotation here in full:

"General Wood, who was given military command of the City of Santiago, has already demonstrated in the most brilliant way what good administration can do for a region like Cuba that has suffered for centuries from hideous misgovernment. Our governor found the city indescribably filthy. He promptly opened the clogged drains; organized a street-cleaning service; enforced compulsory rules for the removal of garbage and domestic waste; established a disinfection-corps in connection with an efficient medical service; put the hospitals into good working condition; cut the death-rate down seventy-five per cent.; averted a yellow-fever epidemic that was considered inevitable; restored, repaired, and greatly improved the water-supply; organized an efficient general police system, discarding the hateful Spanish uniforms;

cleaned up the water-front and devised plans for the dredging and permanent sanitation of the harbor; established a strictly regulated relief-service for the benefit of the thousands of half-starved people who returned to the city from the places to which they had withdrawn in the period of hostilities; restored the administration of justice under his own immediate direction; opened the schools and took the children off the streets, and in a variety of other ways brought order out of confusion.

"General Wood has set the standard at Santiago, and what has been done there must not only be continued and completed, but must, either by General Wood himself or someone else, be accomplished at Havana and at every other important town in the islands formerly administered by Spain that may come under the responsibility of the Government of the United States.

"It is extremely fortunate that General Wood, who is a distinguished physician as he is also a renowned soldier, has shown the War Department exactly what an American military government of conquered Spanish territory can accomplish for the welfare of the innocent inhabitants."[1]

Let us hope and urge that like reforms and work be carried on throughout all the island by American energy and skill; but let us also insist that in the doing of this work and in all the duties required of our troops during our time of occupation and administration every precaution be taken that will preserve their health and lives and advance their welfare. Some sacrifices must be made, but much of the labor can be and should be done by those who are acclimated, and it is only fair to insist that, so far as possible, those whose duty is that of a garrison should have every sanitary precaution taken for them.

But little remains to be said of the nature and history of the exciting causes of the diseases which have been referred to in this article. The excellent articles on "The Cuban Fever Plasmodium," by Dr. Watkins, and on the "Comparative Morphology of Malarial Plasmodia," by Dr. Ewing, published in the MEDICAL NEWS for December 17, 1898, give far better and fuller information of these pathogenic organisms than our space here permits. To these we can undoubtedly ascribe the malarias and paludal fevers that have been mentioned. All are familiar with the causes of enteric fever, dysentery, tuberculosis, smallpox, etc., that so largely add to the high mortality rates of the Cuban cities, and their further discussion is thus unnecessary.

Of the cause of yellow fever alone a few remarks may be new or instructive to some. Despite the careful work of such investigators as Woodward, Sternberg, Freire, and others, the actual cause of this disease has not yet been positively identified, but there is nevertheless every reason for believing it to be a specific living organism. It develops and multiples within the human system, but probably undergoes some intermediate changes after leaving one body before it is able to communicate the disease to another. It is rarely carried by water but may be transported by the atmosphere for short distances, but its progress is interrupted by such slight barriers as walls, streams of water, and even a traveled highway. The usual transmission, however, is by fomites, such as hair, clothing, etc., by which it may be carried long distances. It succumbs to heat, if intense, and to freezing, though a frost, while checking its development and the consequent spread of the disease, may only render it dormant and it may cause new trouble upon the advent of warmer weather. Warmth and moisture are most favorable for its growth and yellow-fever epidemics.

As stated, it is not thought to be indigenous to Cuba or to the rest of the West Indies, and it is said that the disease has practically only been endemic in these islands during the last century. Some attribute its transportation thither to negro slaves brought from the west coast of Africa where it has been prevalent for a very long time. That it can be annihilated and a locality freed from its ravages is practically proven by our experience with cities in this country, such as New Orleans or Memphis, and especially by the example of Jamaica, which at one time was as unhealthful and lacking in sanitation as Cuba, but is now an island remarkable for its salubrity.

The death-rate from this disease in Cuban cities at present may appear remarkably low, but it must be remembered that most of the native population are non-susceptible to it, either through having once had it or by gradual accommodation, and that any others who are still susceptible are comparatively few in number in the various populations. Consequently, we may look for a number of cases and of deaths from this disease, if not an actual epidemic, among our unacclimated soldiers sent to garrison these cities, unless the greatest foresight and care for their protection be taken in every way. How this may be done will be pointed out in a subsequent paper.

[1] From "The Progress of the World," in the *American Monthly Review of Reviews*, for November.

MEDICAL PROGRESS.

Acute Inflammation of the Conjunctiva.—MORAX AND PETIT (*Rev. de Therapeut.*, November 15, 1898) have conducted a series of examinations and experiments during a period of four years in order to determine the nature of inflammations of the conjunctiva. They find that there are three forms of conjunctivitis which are common. One of these, an acute contagious trouble, is due to the bacillus of Weeks, and gives rise to various symptoms more or less grave. The simple cases may give rise in other individuals to grave ones. This conjunctivitis may be accompanied by phlyctenæ or by corneal or sclerotic complications. The best treatment is that by nitrate of silver. The diplobacillus causes a subacute conjunctivitis. This affection is also a contagious one. The authors cite many cases in support of this view. Sulphate of zinc is the best remedy. The third form of conjunctivitis is the gonorrheal. These three kinds of bacteria have the power of multiplying on the surface of the mucous membrane, and of inflaming it. Other bacteria (pneumococci and certain streptococci), though normally present upon mucous membrane without setting up inflammation, acquire this property under certain circum-

stances. Still other bacteria, such as the bacilli of diphtheria, staphylococci, and certain of the streptococci, can only multiply in mucous membrane after some accident has given them an entrance.

VALENCON says that these three varieties of inflammation of the conjunctiva are easily diagnosticated microscopically. He has found protargol most efficacious in the treatment of the first two forms. That due to the bacillus of Weeks is completely healed in five days by solutions of protargol, and the gonorrheal conjunctivitis is much improved and ultimately healed by the same remedy in five per cent. solution, dropped into the eyes several times a day. Conjunctivitis due to the diplococcus is at first apparently benefited by protargol, just as it is by nitrate of silver, but the improvement is only limited, and sulphate of zinc has to be resorted to to complete the cure. Protargol has all the antiseptic power of nitrate of silver and argentamin, and is less irritating and painful. It is therefore less serviceable for granular conjunctivitis than argentamin.

Gonorrheal Stricture of the Rectum.—BERNDT (*Centralblatt. f. Chir.*, December 3, 1898) makes a report upon eighteen strictures of the rectum from gonorrhea (four of them in males), and concludes that they arise independently of ulcers, from the penetration into the deeper parts of the gonorrheal inflammation. Five of the patients had a previous inflammation of Bartholin's gland; six of them had syphilis. In all of the patients except one, the stricture was within 1½ inches of the anus. The gonorrheal process extended, however, a variable distance above this. Hemorrhage, if it occurred, came from ulcers above the stricture. Three patients were discharged unimproved; five were benefited by incision and treatment with bougies; while upon six a radical operation was performed. One of these died upon the second day, of peritonitis, and the others recovered with more or less control of defecation. The operation which ended fatally was done without a preliminary colotomy, and since that time Mikulicz insists on the preliminary establishment of a fecal fistula in all cases.

THERAPEUTIC NOTES.

Treatment of Acne Simplex.—MCKINNEY (*Maryland Med. Journ.*, November 19, 1898) advocates at least three hot baths each week taken at night followed by cold sponging, and a cold sponge bath every morning for patients who are troubled with acne. A light nutritious diet, plenty of exercise, and bowels kept regular, with cascara if necessary, are points not to be forgotten in any case. Tonics, cod-liver oil, phosphates, etc., may be required by the particular patient. The remedy par excellence for acne simplex is calcium sulphid. The proper dose is ½ of a grain, twice daily, and this dose should be steadily increased until four such tablets are taken each day. If the taste is objected to, it may be disguised by sugar coating, or the drug may be given in capsules. In case of excessive gastric irritation, it may be desirable to begin treatment with $\frac{1}{10}$ or $\frac{1}{8}$ of a grain. In the acute stages of the trouble, arsenic does no good, and may do actual harm. At each visit it is well for the physician to spend a little time in gently squeezing out the larger comedones, and curetting the smaller ones with the comedone extractor. The pustules should be lanced at the base in a slanting direction, and the point of the needle or lancet, swung around in the abscess cavity, to break up its contents. If this be done, so that the pus can be squeezed out without disturbing the overlying crust, the resultant scar will be scarcely noticeable. An antiseptic is needed and can best be applied in the form of a soap containing sulphur or bichlorid of mercury, with which the face can be washed at night, so that the patient may avoid going into the air until the irritation caused by the antiseptic has passed away. If there is too much irritation from the use of the soap or other preparation, any of the semi-solid creams may be rubbed into the skin several times a day. Following are other good antiseptic preparations:

℞ Sulphur precip. . . . . ℥ i
Ether . . . . . ℥ ss
Alcohol . . . . . ℥ iiiss.
M. Sig. External use.

The lotion should at first be applied only at night, but after the skin becomes accustomed to it, it may be used advantageously several times a day. The sulphur often causes considerable irritation when first applied, but rarely so much as to cause its discontinuance.

If an ointment is desired, it may prescribed as follows:

℞ Sulphur precip. . . . . ℥ i
Ung. aquæ rosæ, Lanolin } aa . . . ℥ ss.
M. Sig. External use.

Another good combination is:

℞ Potassii sulphid, Zinci sulphat. } aa . . . . ℥ i
Aquæ . . . . q. s. ad. ℥ iv.
M. Sig. External use.

If the skin remains discolored after the papules and pustules have subsided, an ointment of tar and sulphur, or ichthyol and sulphur should be used, rubbing it into the skin for a half-hour each night. The use of very strong stimulants, as naphthol, resorcin, caustic potash, etc., is to be avoided, as their effect is often very injurious to the skin.

The Micro-organisms of Cystitis.—ALBARRAN, HALLE, AND LEGRAIN (*Gaz. heb. de Med. et de Chir.*, November 3, 1898) say that there is no specific micro-organism of cystitis. A great variety of microbes are found in the inflamed bladder. The bacterium coli is by far the most often found. It was present in 131 out of 304 cases examined by them. In 89 of these cases it was the only germ found. They found the pyogenic staphylococci in 70 cases of this same series. These microbes are the only ones which occur at all frequently. In the cystitis which follows gonorrhea, the gonococci are often at fault. This view is contrary to that previously held, which regarded such a cystitis as a secondary infection with other microbes.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

J. RIDDLE GOFFE, Ph.M., M.D., Editor,
No. 111 FIFTH AVENUE, NEW YORK.

Subscription Price, including postage in U. S. and Canada.

PER ANNUM IN ADVANCE	$4.00
SINGLE COPIES	.10
WITH THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, PER ANNUM	7.50

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

SATURDAY, JANUARY 7, 1899.

THE MEDICAL NEWS FOR 1899.

WE have already announced for the New Year a series of special articles on "The Garrisoning of Our Tropical Possessions," which will treat the important subjects of hygiene and sanitation not only for the troops but the inhabitants, and will keep all of our readers informed as to the practical progress that is being made in the solution of these important problems in our new possessions. As tropical medicine now takes on increased National interest for us we shall carefully follow from month to month the Mexican and South American medical societies and journals for advances in this line with the hope too of thus making Pan-American medicine more of a living issue now that our interests in medicine as well as other things give us so much more in common.

In general our special articles during the year will be made a feature and will consist of up-to-date reviews of subjects of practical interest to the general practitioner. Our original articles will maintain the same high standard as ever and in accordance with our established custom nothing will be admitted to the columns for any reason except its actual scientific worth and its practical value and interest to the busy medical man. Our abstracts from medical journals, our accounts of medical and therapeutic progress and of the proceedings of foreign medical societies will be made with the conscientious, painstaking care that has characterized them in the past and with even more completeness. As far as is consonant with the conveyance of a proper comprehension of the subject everything will be put as concisely as possible. We realize how little time the general practitioner has to give even to his medical periodicals so that we shall try to select for abstract and comment only what seems of special practical interest in current medical literature and so put it that its import can be unfailingly grasped and with as little expenditure of time as possible. Our motto is *non multa sed multum*.

FIRST AID ON RAILWAYS.

A RECENT accident on a French railway brings this subject again into public prominence, and in a very practical way. Surgeons were procured, it seems without much delay, but considerable time passed before proper surgical appliances, sterile dressings, bandages, antiseptic dusting-powders, solutions, and the like could be secured for the temporary dressing of the wounds. The result of the outcry on the part of the public because of the delay in the treatment of patients necessitated by the absence of these indispensable articles led to the issuing of an order by the Minister for Public Works requiring all railway-trains carrying passengers to be provided with a certain number of the requisites for prompt, surgical, first aid to the injured.

Dr. Estes, the well-known chief-surgeon of the Lehigh Valley Railroad, in a letter published in another column, commenting on a recent editorial utterance in the MEDICAL NEWS on the "First Aid on Railways," enforces by statistics from the service of that road how much good has been done in the last ten years by the carrying of "first-aid packets" on all trains. The subject is one of great practical interest for the traveling public now so large in America. It deserves serious attention and discussion and should lead to the adoption of similar and even more complete precautions by every railroad in the United States. Only medical men can understand all the significance of such preparations for inevitable accidents in the amount of suffering

that will be relieved and the number of lives that will be saved. All the weight of medical opinion, then, should be wielded to make railroad companies see that their own interests and those of the traveling public in this matter are one.

THE ROTUNDA HOSPITAL OF DUBLIN.

THE clinical report of the Dublin Rotunda Hospital for the year ending November 1, 1897, is of somewhat greater interest than usual on account of the description of the gynecological work of the year. The obstetric portion of the report contains details of the external and internal work of the hospital. It appears that among 2007 deliveries in the external division, there were but five deaths, none of them from sepsis. These fatalities were due, one each, to pneumonia, placenta previa, inversion of the uterus, pulmonary embolus, and cardiac disease respectively. There is an interesting narration of a case of rupture of the uterus, the patient recovering without operation. From the description it is evident that rupture of the puerperal uterus can take place without any of the alarming symptoms which are regarded as classical in the text-books and a diagnosis of which is reached only when, for some reason, the fingers are passed into the uterus.

There were two deaths in the internal maternity service out of 1448 cases, one from rupture of the uterus, the other from septic endometritis. This gives a total mortality for the year of 0.002, a remarkably low rate. Still the aseptic and antiseptic methods insisted upon in both divisions of the hospital's work and the fact that outside patients requiring operation are frequently removed to the hospital, contribute to this excellent showing.

Krauge's method of inducing premature labor—by the introduction of bougies, was tried three times, twice successfully. In the third case, no other method was attempted, but a bipolar version was performed. Inasmuch as this patient suffered from cardiac disease, the nature of which, however, is not stated, opinion may well differ as to the advisability of not attempting other means of inducing artificial labor before resorting to general anesthesia. We may well call into question, too, the recommendation that for accidental hemorrhages, in the face of severe bleeding and the absence of labor pains, the most reliable treatment is vaginal plugging and a tight abdominal binder. The good results obtained by this method at the Rotunda Hospital merely show that in some hands some procedures are satisfactory. The only case of eclampsia during the year was successfully treated by the hypodermatic injection of morphin, the patient delivering herself of a living child three days after admission. Ophthalmia neonatorum was rarely seen, the prophylactic instillation of a 1-per-cent. solution of nitrate of silver being still practised at the hospital.

Turning to the gynecological report, it is to be noted that in the clinical operating-room, the students, the wash-stands, and the sterilizers are separated from the operating-room proper by a partition of plate glass. Interesting data are given as to the preparation of materials, operators, and patients, which differ in no essential particulars from those in vogue in other clinics. Catgut is prepared by alcohol sterilization, the alcohol being slowly brought to the boiling-point while contained in a brass cylinder. Abdominal cases are drained only when there is a large area denuded of peritoneum or from which there is general oozing. A Mikulicz bag is then used for the purpose. Chloroform and ether are the anesthetics preferred, the former only being employed in obstetric work.

THE MIDWIFE QUESTION ONCE MORE.

EVERY one admits that something should be done to lesson the evils necessarily attendant on the midwife as we know her at present in New York City. The need of reform in the matter has been evident for many years. More than a quarter of a century ago, while Dr. Jacobi was president of the New York County Medical Society, the subject was warmly debated. Sporadically, ever since, attention has been called to the evils attendant upon the present system, and measures for reforming it have been suggested. Notwithstanding all this, we are practically in the same position to-day in the matter as we were twenty-five years ago. Let us hope that out of the insistent agitation of the last year or two some practical enduring reform will be evolved. The profession has long enough afforded an undignified spectacle to the world of agreement as to the existence of abuse, and utter disagreement as to the means of correction. We owe it to ourselves that this state of affairs shall continue no longer, and

whether able to accomplish our purpose with legislators or not, that we shall be at least agreed as to what is to be looked for in the matter of reform.

Existing abuses call for reform, but how this reform is to be brought about is where the division of opinion arises. The widwife is a relic of the time not so very long ago when obstetrics did not properly constitute a branch of medicine, and almost any woman who had had children herself was supposed to be capable of taking care of a labor case. It was not until the end of the last century that obstetric lectures in a medical course, in English at least, were delivered for the first time. The advance in obstetric science since then has been most remarkable, and it has all been in the direction of more and more skilled attendance at labor cases. Labor is normally a physiological process, and the doctrine of non-interference is to-day the keynote of obstetric practice. But in the exciting moments that occur in even a normal labor case it requires a thorough grounding in *principle* rather than any mere training by *precept* to keep the attendant in patient, truly scientific inaction.

The mortality of great obstetric clinics has been reduced to a small fraction of one per cent., but it is because obstetrics has become a science as well as an art. The condition of every organ is known as far as possible before labor, in order to provide for possible complications. The condition of heart and kidneys, especially, is looked to, and the often fatal surprises from these organs during parturition guarded against. The highest principles of modern bacteriology constitute the every-day working rule of the clinic. The care of the child has become a special science in itself, and pediatrics has greatly reduced the mortality of new-born children. It is evident that no half-educated, merely trained assistant can ever be expected to master the important details of these sciences, yet they must be practically applied in even normal labor cases; mistakes are serious and may be fatal.

We know that we have sketched an ideal, an ideal after which even doctors do not strive with satisfactory results; but it is the ideal that must be held up unless we would retrograde in the midst of the too faulty real. To such an ideal, obstetric science will sometimes raise its educated practitioners but it can never hope to do so with the class of people that wish to become midwives. To license midwives even after training them would be to put off for long years the application of the benefits of scientific obstetrics to that important class of the community, the many-childrened poor. It would be distinctly a mistake.

There remains the other question, What shall we do just now? Midwives, now practising, have certain vested rights; these, of course, must be respected. They sadly need regulation, however, so that Dr. Tuthill's proposed bill (see proceedings of the New York Medical League, page 29) would seem to be the practical solution of the question. Register midwives already in practice for two years but admit no new ones to registration, and so allow the midwife as a New York institution to disappear. Against this it will be argued that the midwife fills a want for the poor foreign population of the city. The poor we shall have always with us, but we do not look for the continued influx of foreigners into New York in the future that came in the past; while the rising generation born here become, such is the wonderful assimilative power of our institutions, more American than the Americans themselves.

For the poor who are able to pay but little there is the young doctor, so frequent at present, so ready to do such work for a modest fee, and liable, if we read the signs of the times aright, to be still less exacting in the future. For the poor who are unable to pay, organized charity, the signs of which are in the air all around us, will, in the next twenty years, have supplied abundant opportunities to secure scientific obstetric attendance. For the menial services that midwives now furnish in addition to heir duties proper as *sages-femmes*, district nurses on an endowed foundation will have been organized. In these provisions, not in an undignified compromise with half-educated and often characterless midwives, lies the solution of the question of obstetric attendance for the poor of great cities.

We cannot then see any reason for perpetuating the present midwife institution by ill-advised legislation that smacks too much of opportunism and sacrifices the future of obstetric science for the poor, for the questionable benefits of the legal regulation of present day evils. We do see the necessity for present regulation and future abolition of

the midwife, hence, we approve of Dr. Tuthill's proposed legislation, and call on the profession to give it their heartiest cooperation. While thus convinced ourselves, we are perfectly willing to have the other side of the question discussed in our columns, if done so briefly and pointedly.

CHICAGO'S CONTRIBUTION TO ANTITOXIN STATISTICS.

WE cannot refrain from calling particular attention to the diphtheria antitoxin statistics of the Health Department of Chicago, which we publish in another column this week. As may be seen from them, 1713 lives have been saved to the city of Chicago by the antitoxin treatment during the past twenty-six months, while the death-rate from diphtheria during November last, notwithstanding that ten per cent. of the cases were severe enough to require intubation, was only three per cent. Chicago's death-rate from diphtheria before the introduction of the antitoxin treatment was over thirty-five per cent.

If carefully collated statistics ever mean anything, surely here is something to make the most obstinate opponent of antitoxin at least hesitate before he endeavors longer to oppose what so many, after actual practical experience, are coming to regard as the greatest therapeutic blessing ever conferred on mankind. There is only one thing in the history of medicine to compare it with, that is Jenner's vaccination. There were invincible opponents of vaccination, and there are even now those who insist on not crediting it. We know in just what class the anti-vaccinationists belong, and it has now come to a pass in medical affairs that the persistent opponents of diphtheria antitoxin must be classed with them.

We sincerely compliment the Health Department of the City of Chicago on its brilliant results. We feel sure if the methods of the antitoxin departments of those European cities (there are but three, we believe) whose statistics are supposed to still throw doubt on the therapeutic value of antitoxin, were regulated as carefully as Chicago's seem to be, their results would be of a different nature. We cannot close without a word of praise for the succinct forceful way in which the statistics are brought out in order to make them most effective for the public; we commend this method to the health departments of other cities because of the value it possesses in the cause of antitoxin as an educational factor for the masses as well as the profession.

WELL-DIRECTED MUNIFICENCE.

WE reported last week the fact that Lord Iveagh, one of the Guinness family of Dublin, had given £250,000 ($1,250,000) to the Jenner Society of London for the promotion of scientific research tending to the prevention of disease. We cannot well imagine where a liberal generosity seeking an outlet for its philanthropic benevolence in something that would confer the greatest lasting good upon mankind, could find a more worthy object than this. The prevention of disease and its consequent suffering represents the acme of an enlightened human charity. It is to-day without doubt the best thing for the intending charitable to encourage and foster by their gifts and endowments.

Despite the vast wealth of our country and the number of extremely wealthy men it contains, gifts of this kind have not been as frequent as might have been expected. It is very probable that our wealthy classes do not as yet fully understand how much there lies behind the veil in medicine and how much might be done in this country, with the genius for research and discovery that our people have, to solve the great problems at present so insistent in practical and scientific medicine. When the realization of the great field for practical philanthropy that is lying open in this matter shall have come to our liberal wealthy classes—it is the beginning of a new year and we may be pardoned if the spirit of prophecy asserts itself—an era in medicine in America will begin that will eclipse anything medical history records.

Meantime it would seem to be the duty of members of the profession to make clear the possibilities there are for well-doing in this line to men who may have it in their power, by properly directed pecuniary aid, to anticipate the day when in medicine, as in everything else, the course of Empire shall take its way westward.

ECHOES AND NEWS.

A Monument to Charcot.—A monument to Charcot has been erected in front of the Salpétrière. M. Leygnes, Minister of Public Instruction, presided at the ceremony of unveiling.

Deaths of Soldiers at Manila.—The weekly death-list of the United States troops in the Philippines is as follows: Typhoid fever 2, smallpox 2, accident by drowning 1, by gunshot wound 1, ulcer of the stomach 1.

An Unassailable Position.—"No human pen or tongue taught me the science contained in this book, 'Science and Health,' and neither tongue nor pen can ever overthrow it."—*Mrs. Eddy*, the "mother" of the Christian Science Church.

"Medical Progress."—Messrs. Lea Brothers & Company have just announced for publication in March, 1899, the first volume of a new annual, *Medical Progress*, which will be issued in four handsome octavo, cloth-bound, and richly illustrated volumes of about 400 pages each. The several volumes will appear at intervals of three months.

Dr. Hamilton's Fatal Illness.—At the time of writing the obituary of Dr. John B. Hamilton, which appeared in the MEDICAL NEWS last week, it was impossible to secure definite information regarding the cause of his death. His final illness proved to be typhoid fever, and the immediate cause of death was perforation of the intestines.

A Seven-hundred-pound Patient.—Mrs. Hannah McKenzie, who is fifty-eight years old and who is said to weigh 700 pounds, was taken to Harlem Hospital. It required the services of nine men to carry her from the fourth floor of the house in which she lived down to the hospital ambulance. She has had a reputation as the fat lady in a dime museum.

Homeopathic Medical College Election.—At the annual meeting of the New York Homeopathic Medical College and Hospital of Sixtieth street and Eastern Boulevard, Roswell P. Flower was elected president; Giles E. Taintor, vice-president; George W. Clasty, secretary, and Richard M. Hoe, treasurer. A number of committeemen were also elected.

Professor Roentgen Declines.—It is now announced authoritatively that Professor Röntgen has refused to accept the call to the University of Leipzig to succeed Professor Wiederman, who will retire at the end of this semester. Professor Röntgen prefers to retain his present position, that of Professor of Physical Sciences at the University of Würzburg.

Her Sleep That of Death.—A young lady at Hebron, Ind., retired in apparently good health on the evening of Tuesday, the 20th ult. Next morning her relatives were unable to awaken her. Her physician pronounced her to be in a trance and expressed the belief she would soon awaken. On Sunday, five days later, it was discovered that she had been dead for some time.

A "Skirt-Slasher."—An incident worthy the attention of Lombroso occurred recently in a department-store of New York, which illustrates an odd phase of mental pathology. A man was arrested for surreptitiously cutting to pieces in a crowded store the valuable silk skirt worn by a customer. This action is akin to that of spitting tobacco juice or throwing ink upon skirts worn by women, which are more frequently committed than "skirt-slashing."

Christian Science Did Not Save.—The faith in Christian Science of the family of Judge J. W. Eller of Omaha, Neb., is being thoroughly tested. A gasoline stove exploded and burned several members of the family. Two "healers" were called in who prayed at length. When the victims were being told they were not in pain the flesh was dropping from their bodies. Mrs. Eller died, but the other sufferers declared that if they could not be saved through prayer it was not worth while to call for physicians.

Scientists at Columbia.—Hundreds of well-known scientists from all over the country were in this city to attend the meetings of the numerous societies held at Columbia University during the holidays. Seven societies connected with the American Society of Naturalists held their sessions either in the halls of the university or at the College of Physicians and Surgeons; geologists, mathematicians, and chemists also attended. There were anthropological, morphological, physiological, anatomical, and psycological sections.

Pelopathy.—A German clergyman has devised a system of faith-healing which has the merit of illustrating the utmost length to which human credulity will go. He tells those seeking for health that as they were originally made of dust the place to look for health is in mud. He orders them to roll in mud and to refrain as long as possible from rubbing off the coating thus acquired. "And do they do it? Of course they do—scores of them. And if the pelopathist can keep his face straight for a few months he is going to be a rich man."—*New York Times.*

Drunkenness and Insanity Increase.—The Bellevue Hospital authorities have been forced to notice during the holiday season an unusual increase in the number of alcoholic and insane patients. Both wards of this hospital are now crowded. An unusual number of boys have been found intoxicated. There are forty-three patients in the insane pavilion; fourteen persons supposedly insane were admitted in one day. As such a crowded condition of these wards has never been known before, there must be some other reason than the presence of the holiday season.

Smallpox on an Incoming Steamer.—On the arrival of the Hamburg-American-Line Steamship "Pretoria," at the New York quarantine last week, the health-officer learned that one of the passengers, a child three years old, had been ill with symptoms of smallpox. She had been kept isolated. The child and its mother and three other members of the family were sent to the Reception Hospital; nine steerage passengers who had occupied the same compartment were sent to Hoffman Island for observation; all the other steerage passengers were vaccinated; the vessel was disinfected and was then permitted to dock at Hoboken.

Death of Isaac Lewis Peet, LL.D.—Dr. Peet, the Emeritus Principal of the New York Institution for the Instruction of the Deaf and Dumb, devoted most of the 72 years of his life to the amelioration of the condition of those suffering from these infirmities. He was born at the American School for the Deaf at Hartford, Conn., where his father was an instructor. He occupied many positions and was a member of a number of societies and committees, in all of which he labored for the deaf and dumb. He was a prolific writer on all subjects relating to the deaf, their status and education. In 1886 his inaugural address as President of the Medico-Legal Society of New York City on "The Psychical Status and Criminal Responsibility of the Uneducated Deaf and Dumb," attracted much attention among teachers of the deaf, physicians, and lawyers.

Inert Vaccine Lymph in Chicago.—During the year 1897, according to the official report of the Department of Health of Chicago, 126,800 tubes of glycerinated lymph were distributed by the city to its public vaccinators. With those, 82,804 successful results were obtained, *i. e.*, an average of 1½ tubes were required for each success. During the first eleven months of the present year 75,000 tubes in round numbers have had to be used for a little more than 25,000 successful results, an average of nearly three tubes for each success. During the last four months to November inclusive 45,000 tubes have been used for only about 12,000 successes, an average of nearly 4 tubes for each successful vaccination or revaccination. The comment of the Health Department is: "Without further detail at this time it is evident from these gross figures that the producers of glycerinated vaccine have yet much to learn before they can be depended on to furnish a uniformly potent as well as pure lymph."

The New York Hospital and the State Board of Charities.—There is a controversy between the Society of the New York Hospital and the State Board of Charities. The former denies the latter's right to inspect the Hospital. The State Board takes the position that they are merely fulfilling a mandatory provision of the amended Constitution of the State of New York defining the duties of the Board. The Constitution says: "The Legislature shall provide for the State Board of Charities which shall *visit and inspect* all . . . institutions, whether State, county, or municipal, incorporated or not incorporated, which are of a charitable . . . eleemosynary, correctional, or reformatory character, excepting only such institutions, etc." The only exceptions are those institutions made subject to the visitation of the Lunacy and Prison Commissions. Upon this authority the Board expect to act unless the Hospital contends successfully that under its royal charter from George III. it is independent of this provision of the constitution.

Diphtheria Antitoxin in Chicago.—During the month of November, 1898, according to the reports of the Department of Public Health of Chicago, 168 cases of diphtheria were reported to the department and examined bacteriologically. Of these 98 were found to be true diphtheria caused by the Klebs-Löffler bacillus and were treated with antitoxin. Four patients remaining over from the preceding month were also under treatment. Of the 102 patients 97 are reported as having recovered, 2 remain under treatment, and 3 have died. A mortality, therefore, is shown of 3 per cent. in completed cases. Ten of the patients treated required intubation so that the diphtheria during the month was by no means of a mild form. Two of the 3 deaths were in intubation cases and all 3 of the fatal cases were first seen by the inspectors of the Department of Health later than the fourth day. This is certainly a remarkable showing for antitoxin and statistics so kept will soon furnish us with an answer to even the last of the obstinate doubters of serum-therapy. To this report for the month is appended the following details of the results obtained in Chicago since the original introduction of the antitoxin treatment of diphtheria by the Department of Health on October 5, 1895: During the succeeding twenty-six months to date the physicians of the department have examined 5739 cases of reported diphtheria. Of these 3956 were found to be true diphtheria and all but 134 (treated by family doctors) were treated by the department. Out of the 3822 patients thus treated 3763 recovered and 259 died, a mortality of 6.7 per cent. Before the introduction of antitoxin the mortality of diphtheria in Chicago was 35 per cent. "*At this rate there would have been 1337 deaths among the number actually attacked instead 259*"—a clear gain of *1100 lives* in a space of scarcely more than two years to say nothing of the amount of suffering of the patients and worry on the part of parents and friends saved by this latest addition to therapeutics. But that is not all. Where these children were there were also 3633 other children exposed to the infection and these were immunized, being given the preventive doses of antitoxin. Only 30 out of this number were subsequently attacked by the disease; they all had light attacks and promptly recovered. Of the 3600 exposed, in all probability at least one-half would have contracted the disease but for the immunization with antitoxin and, of this number, if the mortality of pre-antitoxin days obtained, there would have been 635 deaths or a total of 1972 deaths from diphtheria during the last 2 years and 2 months. In 26 months then there has been a saving to the city of Chicago, thanks to diphtheria antitoxin, of 1713 lives.

SPECIAL ARTICLE.

THE REPORT OF THE LOOMIS SANATORIUM FOR THE YEAR ENDING NOVEMBER 1, 1898.

THROUGH the courtesy of Dr. Stubbert, the Physician in Charge, we have received the annual report of the Loomis Sanatorium for Consumptives. In view of the recent attempt in England at some concerted action for the prevention of this disease, under the patronage of the Prince of Wales and Sir Wm. Broadbent, the present report has a particularly timely interest.

The primary objection to all such compilations is that they are invariably presented in a statistical form. Very few men are able to handle statistics; a little knowledge of the art, as of learning, is a dangerous thing. As was said some time ago in reviewing a statistical effort of a life-insurance medical director on the subject of "Phthisis:" "They don't even lie truthfully," and while we have not the slightest doubt that much good has been accomplished by the faithful and scientific work done at this particular sanatorium, we are compelled to question the conclusions which are drawn in the report before us.

Before proceeding to an analysis of this report we must take issue with the author for his use of the word "cured." It is an accepted fact that according to our present light it is practicably impossible to decide when the word "cured" should be applied to consumptives, especially in the case of females.

It is a common experience to meet patients who, after several years' residence in Colorado, have returned to the East, apparently cured, but who, after a short residence in New York, Philadelphia, Baltimore, or other Eastern cities, have again developed the disease and who have either died or been compelled to return to a high altitude.

This report gives the results of a year's work in the sanatorium, from which it seems that 204 patients had been treated during the year ending November 1, 1898, 78 of whom were there on November 1, 1897. The patients are divided into two classes: (1) Those who remained three months or less. (2) Those who remained longer. Of the total 204 the number described as "cured" is 28; of this number 10 are put down in class 1 and 18 in class 2, the latter being those who had been there over three months. In this connection the director says: "It is interesting to note that of those patients discharged after a residence of three months or less six per cent. were "cured," while among those who remained longer than three months eleven per cent. were cured. Here we must take issue with Dr. Stubbert, for while these cases had undoubtedly so improved that there was no longer any bacilli in the sputa or apparent lesion in their lungs and while they may have seemed in excellent health, the time was too short between the departure of any one of the twenty-eight and the making of this report to justify even the most hopeful in describing them as "cured." Again we must ask the director why he makes no distinction between female and male patients, a very important point it seems to us, for it is well known that phthisis is far more fatal in the female than the male, owing particularly to the fact that tendency to the tuberculosis is inherited through the mother and secondly to the more or less confined life of the woman, which tends to develop the disease. And this latter influence especially holds after her dismissal from a sanatorium even as "cured." We are, therefore, surprised that Dr. Stubbert, in making up his report, makes no distinction between male and female patients.

Of tne 204 patients in the sanatorium 67 were "discharged improved;" this is a very unsatisfactory statement and of very questionable application. We have in mind, for example, the case of a "Rough Rider" who on August the 19th had tubercular trouble at the apex of the left lung and bacilli in his sputum; after being mustered out September 16th he increased many pounds in weight, his cough stopped, and the bacilli disappeared from his sputum. Two months later (indeed up to December 1st he was in splendid health) he broke down and was sent West with all the symptoms of tubercular lung trouble. We could give many such instances in our practice and it is for this reason that we are inclined to criticise any report treating of this disease in which patients are described as "discharged improved," or "with the disease arrested." These criticisms apply both to class 1 and class 2 in this report, where the patients are described as "cured," "disease arrested," or "improved." We do not wish to seem hypercritical for we know great good has been done by the Loomis Sanatorium in combating this dread disease, we desire only to emphasize the fact that great care should be exercised before drawing final conclusions from combinations of what are ordinarily classed as statistics.

The remainder of this report is more useful and interesting. Dr. Stubbert states that there is far more improvement among the patients during the winter than the summer months and his experience has shown that his patients "brave with impunity the cold northwest winds" and that he has seen eighty patients gather at meals from their cottages day in and day out "without the least detrimental effects." In this connection he states that "the results obtained during the three cold seasons at this sanatorium seem to tend to revolutionize the popularly accepted ideas of the "injurious effects of wind and stormy weather in *incipient* cases of tuberculosis. We do not understand why he speaks of "the popularly accepted ideas," for even more severe conditions exist at Davos, which is to-day and has been for ten years, the place of all others to which cases, not only of incipient, but of well-developed phthisis have been sent by French, English, and Swiss experts on tuberculosis.

We cordially agree with Dr. Stubbert's conclusions that the patients should be encouraged to take constant exercise and be in the fresh air (under ordinary conditions) as long and as frequently as possible.

The balance of the report is taken up with the auxiliary treatment of special cases with various remedies. What interests us more especially is the experience with the antitubercular serum. He shows that twenty-seven per cent. of those treated lost the tubercle bacillus, although he does not state that they have been followed after their dismissal from the institution. It is but fair, however, to quote his statement: "I have lately examined between fifteen and twenty cases treated with serum and have not found one that redeveloped the disease; all have been enabled to remain in their homes and at their work and have been away from the sanatorium for periods varying from six months to a year and a half."

Of the effects of the United States Government serum of De Schweinitz he says: "I believe it to be the duty of the profession to continue the clinical administration along this line, since the three apparent effects noted from

the use of this serum have been: (1) "Reduction of temperature." (2) "Decrease of the bacilli." (3) "Possible immunity conferred upon patients after returning to their homes."

With reference to his use of antistreptococcic serum he says that it was naturally used in the hope that he could thereby do away with the streptococcus so that he would then be left to deal with the tubercular affection alone. With this end in view he employed in ten patients the Pasteur serum, selecting, of course, only such patients as showed the presence of the streptococci. Judging from the ten cases given it caused the disappearance of the streptococci for a time at least, and though its action was slow it apparently should leave the way open during that time for a more successful use of the De Schweinitz serum.

The report finally deals with forty cases of tubercular laryngitis; of which Dr. Stubbert says that "43 per cent. of the *ulcerated* cases have been discharged cured." This is certainly a very gratifying result; but a long experience with tubercular laryngitis in this country, in England, Germany, in St. Petersburg and Moscow compels us to believe that the word "cured" should not have been used.

The report shows that a number of other drugs were used without specially good results; among others the new South-American "Kalagua." It would seem from his experience that this has certain merits but we question whether the results claimed for it by the "Medical National Society of Columbia" are justified.

Finally Dr. Stubbert's experience with what he describes as the "pneumochemic" treatment corresponds entirely with our own experience with the pneumatic cabinet. It is of use only where there is bronchorrhea and excessive cough.

In any event this report is exceedingly interesting. The methods and practice at the Loomis Sanatorium mark a distinct advance in the treatment of tubercular disease and every encouragement should be given to Dr. Stubbert to continue his further scientific efforts toward the prevention and cure of this most fatal malady.

CORRESPONDENCE.

FIRST AID ON RAILWAYS.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—The interesting and valuable editorial which appeared in the December 3d issue of your journal should have the hearty thanks and support of all intelligent and earnest men who are connected with railway management, in either the surgical or purely executive departments.

There is no question that the Belgian and English railway systems are far ahead of ours in the matter of systematic methods for rendering first aid on their lines, and in this country the West and South have better systems, as a rule, than the roads in the East and North. Indeed, I know of one large system which enters New York City which has not even a surgeon connected with its lines. If public opinion were properly educated in this matter this could not be possible.

Railway surgeons have hitherto been regarded as rather an inferior class by the erudite members of our profession, and their efforts and accomplishments in the matter of hygiene and preparations for meeting medical and surgical emergencies along the lines of railways have either been unrecognized by the leading medical journals or have been allowed to go absolutely unsupported. It is a matter for mutual congratulation, therefore, that the MEDICAL NEWS has taken up this most important matter, and I trust it will continue to advocate the necessity of proper preparation for meeting surgical emergencies along the lines of railways until public opinion shall force every system to have a thoroughly equipped surgical department and adequate arrangements for giving modern and efficient first aid to the injured. I feel that I am entitled to speak emphatically and strongly concerning this matter as I have some strong data to support the proposition that the NEWS so well expresses, namely, "Every dictate of humanity as well as financial interest demands its enforcement."

In 1886, acting as chief surgeon for the Lehigh Valley Railway I introduced on the road a system of "accident cases" to be used for injured persons. The road at that time had its line well supplied with local surgeons but there was absolutely no provision for supplying simple aseptic dressings and means for controlling hemorrhage. In many cases the lack of these I found resulted in loss of life. Surgeons summoned hurriedly rarely carried with them the necessary appliances for controlling hemorrhage and very rarely had properly prepared materials for temporarily dressing an injury so that it might be properly protected and run no risk of further infection while the injured person was transported to a hospital or to his home. The soiled handkerchiefs and soiled "waste" from the locomotive, which the employees were accustomed to use in their efforts at first dressing simply made rapid recoveries after injuries impossible. These accident chests were intended to furnish simple appliances and aseptic dressings, with some antiseptic substances, to be used by the surgeon; they were put up in a easily portable and compact form and enclosed in a tin case.

A printed list of the contents of the tin case and a few simple directions for meeting some emergencies was pasted inside the lid of each chest. I also gave some personal instruction to station-masters on first aid to the injured. These cases were at first located at the stations along the line and with each wreck-train. It was found that they were so important a factor in caring for injured people that now not only the stations and wreck-trains have them but every passenger-train conductor must carry one in his "kit," and the cabooses of the freight trains and special coaches are also supplied with them.

Space will not permit me to go exhaustively into the results of the use of these cases—it will suffice to say that my statistics show a saving of a little more than *sixty per cent. of lives* since the use of these cases as compared with the old régime, and time of disability reduced one-

half. The saving of suffering no one can properly calculate; it must, however, be very great indeed.

Very truly yours,
W. L. Estes, M.D.

ST. LUKE'S HOSPITAL,
SO. BETHLEHEM, PA., December 31, 1898.

[The editor heartily commends this plan, as outlined by Dr. Estes, and regrets that he is unable, on account of its length, to publish the list of articles contained in the accident chest, as well as the "Rules for the Treatment of the Injured Immediately after the Accident." If Dr. Estes has a supply of these slips on hand he doubtless will be pleased to furnish copies to those who are particularly interested in this very important subject.]

SCHLEICH'S MIXTURE FOR GENERAL ANESTHESIA CONDEMNED.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—In the issue of the MEDICAL NEWS for November 12, 1898, I published an article, entitled "Clinical Observations in Regard to General Anesthesia by the Schleich Mixtures," which I summed up by saying that the Schleich mixtures are easily taken; that they may be used in all cases in which general anesthesia is not contraindicated; that anesthesia can be induced in a short time and kept up with small amounts of the fluid; that there is little accumulation of mucus, little vomiting, and hardly any cyanosis; that there is no bad effect on the kidneys; that the heart is not much influenced by it, although somewhat weakened; but that there is *some danger in regard to respiration;* and finally, that it affects the patients much less than ether or chloroform. I, therefore, recommended this new anesthetic for general use.

I take it to be my duty to inform the readers of the MEDICAL NEWS that I have been compelled to change my opinion in regard to the safety of these mixtures. In the article I stated that the real danger with Schleich's mixtures lies in their influence on the respiration, and I reported three cases in which there had been bad arrest of breathing, but in each case there was some complication which might be regarded as a mitigating circumstance. But now within twelve days I have had two similar occurrences in comparatively healthy women. One was a woman twenty-three years of age, in whom I extirpated Bartholin's glands on account of a fistulous tract remaining after an abscess. The abdominal muscles remained stiff, and when the anesthetist gave her more, she stopped breathing. She was immediately treated according to Sylvester's method, administration of oxygen, and pulling on the tongue. She recovered soon, but I then ordered ether to be given instead of Schleich's mixture.

The other was a forty-six-year-old woman, whom I operated on for fibroma uteri. All her other organs were healthy, but she became blue in the face and stopped breathing. In this case I saw again the excellent effect of the new method of revival invented by a Frenchman (Arcachon?). It consists simply in moving the tongue forward and backward. This interrupted pulling forward has appeared to me to have a more immediate effect in reviving the asphyxiated patient than any other remedy I am acquainted with, and it can, of course, easily be combined with other measures.

Thus having had five cases of dangerous respiration among little more than a hundred patients, to whom Schleich's mixture was given, I do not feel warranted in using it again in spite of all its excellent qualities, and I hereby beg to revoke the endorsement I have given it verbally and in print.

Yours truly,
HENRY J. GARRIGUES, M.D.

NEW YORK, December 24, 1898.

THE USE OF QUININ IN MALARIA.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—In the MEDICAL NEWS for December 17th, in your special article on "The Present Status of Opinion upon the Use of Quinin in Malaria," I find this statement: "Here and there some one with but small experience of malaria, or perhaps none, has expressed agreement with Koch's opinion. The voice of our own Southern medical men, of the English medical men in India, and of the medical men of Brazil and Italy, have been as a unit against Koch." Is not that statement too strong? The idea is not new; it is not Koch's.

Nearly all my professional life has been passed in a highly malarious country, and among the physicians there, who are not men of "small experience of malaria," the belief is quite common that quinin *does* cause hemoglobinuria. That statement of the writer should be somewhat modified. Again, "Another convincing consideration is that even in the midst of the genuine malarial hemoglobinuria the only remedy that can be depended on is quinin." Is that statement correct? Men who write books and most of the articles for medical journals live in cities where relatively few cases of malarial hemoglobinuria occur, and these scarcely of the worst type. They usually recommend quinin—but theoretically. Dr. N. S. Davis wrote on this subject, evidently though not from experience: "For accomplishing the two first objects large doses of quinin, opium, and astringents have been frequently used but with very little success." ("Practice of Medicine," page 203.) Then he quotes Dr. F. C. Fohs of Alabama, and Dr. G. B. Malone of Arkansas in support of a treatment in which quinin is not used. Drs. Fohs and Malone were evidently not men "with but small experience of malaria."

Where I had considerable experience with the disease, in the Arkansas River bottoms, the idea prevailed, accepted from the researches of Laveran, that the plasmodium malariæ was in the red blood-corpuscles, and when the plasmodium destroyed its host, it resulted, at the same time, in the destruction of the plasmodium itself, and if the patient could eliminate the disintegrated blood-corpuscles and plasmodium a cure would follow. All the persons I personally knew to die of the disease died of suppression of urine consequent upon a nephritis. Can one relieve a suppression of urine with quinin, given in any size dose or in any manner? Cases of hematuria, I grant you, have been cured with quinin, but hematuria is not

hemoglobinuria. That quinin may cause hemoglobinuria is possible; that it does, in these cases, is not proven, and not very probable. Personally, I do not believe that it does, but, like others, I do not know. Let Koch adduce his proof. In the meantime a proper spirit of inquiry is more conducive to the growth of medical knowledge than is dogmatism based upon our present imperfect knowledge of the disease. Very truly yours,

W. B. DEFFENBAUGH, M.D.

820 FRANCIS STREET,
ST. JOSEPH, MO., December 24, 1898.

INFIRMARY FOR STUDENTS AT YALE UNIVERSITY.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—When, in your issue of December 24th, you assert to give "Honor to whom honor is due" in the matter of an infirmary for sick students in connection with a university, and through your correspondent, Dr. Hoag of Indianapolis, assign the priority to Cornell as against Harvard, I am constrained to call your (and his) attention to the fact that the "Yale Infirmary" on Prospect Street, this city, has been open and in successful operation since December, 1892.

The funds to build the Infirmary were contributed almost entirely by ladies, the first considerable amount being raised by a public performance at the Hyperian Theater in this city of the Greek play "Antigone," in which the performers were all ladies of New Haven. The affair proved a great success, both artistically and financially, more than $2000 being realized for the fund, and the impulse thus given aroused enthusiasm in distant cities, and the wives of loyal Yalensian graduates, the mothers *in esse* and *in futuro*, interested themselves to raise additional funds, so that in a little more than a year a building costing with its equipment nearly $40,000 was finished and ready for occupancy.

The first patient was received on December 16, 1892. In the following year the property was formally turned over to and accepted by the corporation of the University, and the public announcement thereof made in the report of President Dwight for that year. The building accommodates comfortably about fifteen students, and there has been an average attendance since its opening of eight. It has been the object of much favorable criticism, especially by Harvard men. President Eliot and others, notably Drs. Clarence J. Blake, Henry P. Walcott, and George W. Fitz, have interested themselves to visit it, and there has been much correspondence with regard to its workings. The statement in your issue of December 10th, that the Harvard infirmary (yet to be built) "is the first erected at any of the large universities," certainly did not emanate from a Harvard man!

The Yale Infirmary comes from no single contribution or family, however praiseworthy such a memorial may be, but, like its magnificent gymnasium, it is the evidence of the unabating love and loyalty of its Alumni and their friends. Respectfully yours,

"C."

NEW HAVEN, CONN., December 26, 1898.

[If any university in the country antedates Yale in this work let it now speak or ——.—ED.]

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent]

A NEW WATER-SUPPLY SUGGESTED FOR PHILADELPHIA—HOSPITAL BEQUEST—PERSONAL NOTES—OBITUARY—THE CITY'S HEALTH FOR 1898—HEALTH STATISTICS.

PHILADELPHIA, January 3, 1899.

THE most sensible solution of the city's water problem yet presented is to be found in a communication from one of our Councilmen to Director of Public Works, Thompson. The writer suggests that the city lease or buy land surrounding some of the lakes and streams in Monroe County and that by means of an aqueduct the water be brought to the city without the necessity of filtration. Land can be purchased very cheaply in this region and the topography of the country seems peculiarly suited to the creation of large water-sheds, surpassing in fact the natural fitness of New York's supply.

This water-way is in the Pocono Mountains, a region to which the State Board of Health has recently called attention as a health-resort, and the water of the mountains is famous, among those familiar with it, for its purity. A few years ago there were gathered together at one of the summer hotels in this region a number of men who earnestly discussed the feasibility of conveying this magnificent and apparently inexhaustible supply of water not to Philadelphia but to New York and other cities along the route. The streams are unused except for trout-fishing carried on by some associations and flowing down long, deep valleys and, being from 1000 to 1500 feet above tide-level, they offer a truly, simple and magnificent opportunity to relieve the city from our death-dealing Schuylkill water.

By the will of Paul Jagode, $5000 is left in trust for the benefit of Quicko Thomas, "a poor and pitiabel epileptic," and upon the latter's death the money is to revert to the German Hospital for the maintenance of a free bed.

Director Riter, of the Department of Public Safety, has appointed Dr. John D. Devereaux an assistant medical inspector; Dr. Francis T. Stewart has been appointed chief resident of the Pennsylvania Hospital to succeed Dr. J. C. Starbuck, Dr. E. H. Wiggins becoming resident in the former's place.

At a meeting of the Board of Trustees of the Philadelphia Polyclinic and College for Graduates in Medicine held December 20th, Dr. Francis R. Packard was elected Dean of the College Department: Dr. Edward Martin resigned the Chair of Genito-urinary Surgery and the Chair was abolished; Dr. George E. de Schweinitz resigned the Chair of Diseases of the Eye, the Chair was abolished and an Emeritus Chair was created to which he was elected as a mark of appreciation of his services rendered the institution.

Dr. John Lindsay, Secretary of the Philadelphia County Medical Society, died at Riverton, New Jersey, on De-

cember 23d, of pulmonary tuberculosis. He was a graduate of Jefferson Medical College and Assistant Demonstrator of Anatomy at that institution.

Dr. John Sheets, a graduate of the University of Pennsylvania, died last week, aged forty. After studying abroad he made diseases of the throat a speciality and came to this city eighteen years ago, being at the time of his death a member of the Philadelphia County Medical Society and of the Medical Club of Philadelphia.

With the advent of a new year a retrospect of the city's health during the past year may be of some interest for it has been remarkable in some ways. The total number of deaths reported for the year was 23,790, a ratio of 19.18 per 1000 of population; 5036 were of children under one year of age, 2962 of children between one and five years old and 5498 occurred in people over sixty years of age. Notwithstanding the fact of our having had quite a severe epidemic of enteric fever and the fact that many sick soldiers were brought to this city, the the ratio of deaths per 1000 of population is next to the lowest of any year during the past ten, 1897 being the year in which the ratio was 18.72 as against 19.18 for 1898.

As to the present health of the city, the outlook is not especially cheerful, the number of deaths for the past week having reached 725 which is an increase over the week before of 75 and an increase for a similar period for 1897 of 264. Influenza continues to be an important factor in the number, 68 deaths being ascribed as directly due to "La Grippe," an increase of 39 over the week before and of 65 over the week of December 17th, surely a conclusive proof of the existence on no small score of a true epidemic.

The total number of deaths occurring in Philadelphia for the week ending December 31st, as reported at the Health Office, was 725, of which number 176 occurred in children under five years of age. The total number of new cases of contagious diseases was 230, reported as follows: diphtheria, 73 cases with 30 deaths; scarlet fever, 32 cases with 2 deaths; typhoid fever, 125 cases with 21 deaths.

SOCIETY PROCEEDINGS.

THE NEW YORK MEDICAL LEAGUE.—MANHATTAN SECTION.

Stated Meeting, Held Friday, December 16, 1898.

SUBJECT of the evening,

MIDWIVES AND THEIR ILLEGAL PRACTICES.

W. A. PURRINGTON, ESQ., read a paper on

SOME LEGAL ASPECTS OF THE SUBJECT.

Inasmuch as labor is a physiologic process, midwives in following their profession do not strictly come under the law regulating the treatment of disease. There is no legal definition of obstetrics, and it would be extremely difficult to formulate a satisfactory one, so that the midwife's practice of obstetrics has been simply an acknowledged fact. Certain statutes assume the existence of midwives; certain cities and counties have licensed them. This is all the legal status they possess. As to the question of formal recognition by law and their regulation and registration, it is not an easy one. There are too many statutes on the statute-books already, and the enforcement of such regulatory laws is very unsatisfactory. It often gives opportunity for the practice of blackmail on the part of inspectors. Doubtless, if a law were desired one could be formulated to cover the ground, but appeal to legislation has been too frequent in such matters, and every other means for the relief of existing abuses should be tried first.

Owing to his unavoidable absence because of illness MR. ELBRIDGE T. GERRY'S paper,

MIDWIVES AS ILLEGAL PRACTITIONERS,

was read for him. He told of the efforts of the Society for the Prevention of Cruelty to Children to break up certain midwife institutions in which abortion was evidently practised. The directresses of these places had taken the precaution, in a number of instances, to have their institutions legally incorporated, their nearest relatives constituting the board of trustees. This has made it a little more difficult to proceed against them. The society would welcome amendments to the present laws that would bring such institutions more directly under legal supervision, for such regulation is badly needed.

DR. THEO. K. TUTHILL read a paper, entitled

WAYS AND MEANS OF DEALING WITH THE ILLEGAL PRACTICES OF MIDWIVES.

He considers that all are agreed that the midwife is an evil. The practical regulation of the question, however, is bound up with many knotty points not easy to unravel. Midwives at present practising have certain vested rights which must be respected. The only way out of the difficulty seems to be to bring present midwives under legal surveillance by requiring registration, but to refuse to register any who have not been in practice for at least two years. With the gradual disappearance of the present midwives, and no additions to their ranks, the difficult problem would in course of time settle itself. This is, of course, a compromise for the present, but it will decrease the evils of the midwife system as now existing, and will lead to their ultimate extinction. It is such a compromise as had to be made when the question of the legal regulation of the practice of medicine came up. The vested rights of those already in practice, though without diplomas, had to be respected.

Dr. Tuthill then read the draft of a bill for the regulation of the midwife problem along these lines. Some of its special features are: No midwife is to be allowed to report a still-birth. The death-certificate for such cases must come through regular medical channels, as for all other deaths. Midwives are not allowed to continue in attendance at abnormal cases without calling in a physician. Any labor protracted beyond eight hours is to be considered as abnormal. The performance of any internal manipulation by a midwife, or the use or possession of any obstetrical instruments by one, is to be con-

sidered a misdemeanor and punishable as such. As stated, of course, the main feature of the bill is that no midwife is to be registered who has not been in practice two years at the time the bill becomes a law, and no registrations are to be allowed for any reason thereafter, thus providing for the gradual disappearance of the midwife.

DR. GARRIGUES was unable to be present, but communicated by letter the views he would have expressed in the discussion. He considers that with the number of doctors in this country the midwife is superfluous. If there should be any question of womanly reluctance to a man's attendance in a given case, women physicians are now at hand. The system of midwives inevitably has been a source of serious evils. They are criminal in many cases, known to be abortionists, a blot on our civilization. They are quacks, and under the circumstances it is scarcely possible to keep them from practising quackery. The delivery of a woman in our day is bound up with too much scientific medicine for us to hope to be able to train midwives properly, considering the class of women who wish to enter the calling. There is not alone the actual delivery, but the medical condition of the woman before labor, manipulations requiring skill and a knowledge of the importance of surgical bacteriology during labor, besides the highest principles of pediatrics during that first trying month of a child's existence. There is no excuse in poverty or modesty for the midwife in our day, for doctors and doctresses can be obtained. Let us, then, get rid of this crying evil.

DR. J. S. PETERSON thought that the midwives of the present day know as much as many of the doctors of thirty years ago, many of whom had had but six-months' medical teaching.

DR. GEORGE T. HARRISON related some characteristic anecdotes illustrating the ignorance of the midwife of physiology and anatomy. On one occasion, called in to a labor by a midwife, he delivered a still-born child. He soon saw that his efforts to resuscitate it would be vain, so he turned his attention to the mother. The midwife asked to be allowed to make a trial at restoring the child to life, and he gladly gave his permission. A few minutes later he noticed, to his surprise, that she was blowing with all her force into the umbilical cord. She told him her idea was to inflate the child's lungs, and so get it to breathe.

DR. M. B. FEENEY stated that in the down-town districts the midwives have considerable influence over the foreign voting population, and that any bill that seemed liable to make matters unpleasant for them would, he felt sure, be opposed by Assemblymen from certain districts, who would be won over by the political influence of these foreigners.

NEW YORK ACADEMY OF MEDICINE.—SECTION ON GENITO-URINARY DISEASES BEFORE THE ACADEMY.

Stated Meeting, Held Thursday, December 15, 1898.

DR. SAMUEL ALEXANDER read a paper, entitled

OBSERVATIONS UPON THE PATHOLOGICAL ANATOMY OF CHRONIC ENLARGEMENT OF THE PROSTATE, WITH SPECIAL REFERENCE TO THE CAUSES OF THE MUSCULAR INSUFFICIENCY OF THE BLADDER.

The paper was illustrated by a large number of lantern-slides in which were demonstrated various phases of prostatic enlargement macroscopically and microscopically. It was made clear that the original change in the hypertrophy of the prostate is an increase in the glandular elements, and that the fibrous condition so often seen in old cases is secondary and degenerative in character. The physiological purpose of the prostate as a sexual glandular organ seemed thus to be clearly brought out. It is not the enlargement alone causing mechanical obstruction that is the cause of the residual urine and other prostatic symptoms, but the fact that the enlargement by interferring with the insertion of the muscle of the trigone prevents it from properly performing its function of emptying the bladder. Hence it is, that at times even when there is no demonstrable enlargement of the prostate, when no prostatic tumor can be felt through the rectum and an ordinary catheter slips into the bladder easily, there may still be residual urine and other prostatic symptoms. In these cases there will usually be found an enlargement of accessory but distinct nodules of prostatic tissue situated just beneath the mucous membrane of the trigone. A number of perfect specimens of this condition, to which Dr. Alexander was one of the first to direct surgical attention, were shown. The symptoms occasioned by this condition have usually been attributed up to this time to a fibrous change in a normal-sized prostate.

The surgical treatment of this hitherto unstudied condition constitutes a very interesting problem for modern surgery, and one that no present method of surgical interference touches upon.

What the speaker especially insisted on is the manifold character of the pathologic changes (as may be seen from the series of microscopic sections and photographs of prostates) that underlie the condition known clinically under the simple name of hypertrophy of the prostate. Directly causative of the symptoms of the affection are especially the enlargement of accessory prostatic material existing in the trigone and the enlargement of the middle lobe, both of which interfere with the insertion of the muscle underlying the trigone, and so with its function of emptying the bladder.

DR. ABRAHAM JACOBI presented to the Library of the Academy, on behalf of Dr. Lothar Voss, formerly of New York but now of Germany, a copy of the original edition of Gasparo Aselli's work, "De Lactibus," a treatise on the lymph-vessels, and took occasion to say something of the book and its donor. The lymph-vessels had been seen by Hierophilus and others of the scientists of antiquity, but their purpose had been entirely misunder-

stood. They had been thought to be mainly carriers of air. Gasparo Aselli of Bologna, on July 23, 1623, during an anatomical demonstration, had first realized their true significance. He had found the valves in them so situated as to allow their contents to flow only in a different direction to that of the veins. His further study of the subject had led to the publication a year after his death of the book now presented to the Library of the Academy, and which was the first book ever printed that contained colored plates. Only two other copies of the first edition are known to exist, and only one of these is a perfect copy. This is in the library at Leipzig, while there is an imperfect copy at Breslau. Copies of the later editions are much less rare and valuable. The donor, Dr. Lothar Voss, was formerly a resident of New York and a member of the Academy. He returned to Germany and became a non-resident member of the Academy. That he did not lose his interest in it is proved by the present valuable gift. He is at present living in a little town in Westphalia from whence he sometimes makes pilgrimages to see the great surgical clinics and collect old books, for he is a great bibliophile. Through some error, either of the printer or of the Secretary of the Academy, Dr. Voss' name has been allowed to disappear from the list of Non-resident Fellows. Dr. Jacobi asked that every Fellow insert the name in his own list of the Members of the Academy, and that the secretary be instructed to see that no list of the Fellows be hereafter given out without Dr. Voss' name being included.

At the suggestion of the President, Dr. Janeway, a motion was carried to the effect that Dr. Jacobi should give expression to the vote of thanks which the Academy tendered to Dr. Voss for his valuable gift.

REVIEWS.

THE MEDICAL NEWS POCKET FORMULARY FOR 1899 —Containing sixteen hundred prescriptions representing the latest and most approved methods of administering remedial agents. By E. QUIN THORNTON, M.D., Demonstrator of Therapeutics, Pharmacy, and Materia Medica in the Jefferson Medical College, Philadelphia. In one wallet-shaped volume, strongly bound in leather, with pocket and pencil. Price $1.50, *net*. Philadelphia and New York: Lea Brothers & Co., 1899.

NO more appropriate words of introduction to this handy volume can be made use of by the present reviewer than those of its author, who says in the preface: "That there is a broad and legitimate field of usefulness for works of this character is self-evident, for even the best-informed practitioner may at times overlook an appropriate drug, and the young physician will perform his duty better, both to his patient and himself, if he has at hand the collective experience of the profession. No man of independent thought will be hindered in his development by having the best information placed conveniently at command."

These sentiments meet with our hearty approbation, and the more so because in this instance the author has placed this best information of which he speaks before us in a form which could not be improved upon. Diseases are arranged alphabetically throughout the book, and under each head the prescriptions cover not only the acute conditions, but also those of a chronic nature, as well as the ordinary complications. All doses are stated in both the apothecaries' and metric system. The work has been well and thoroughly done, and all recent remedies and combinations which have been proved of undoubted value in practice find a place.

The book is of convenient size, is very attractively printed and bound, and should find a place on the table or in the pocket of every practitioner who prides himself on being abreast of the times.

CONTRIBUTIONS TO ORTHOPEDIC SURGERY. By A. SIDNEY ROBERTS, M.D., Late Surgeon to the Philadelphia Hospital; Orthopedic Surgeon to the Out-Patient Department in the University Hospital, Etc. Privately printed. Philadelphia: 1898.

THIS is a "memorial volume" to the late Dr. A. Sidney Roberts by Dr. James K. Young, who ardently eulogizes the deceased in his introductory biographical sketch. This collection of Roberts' writings embraces the more commonplace orthopedic topics – club-foot, spondylitis, knock-knee, bow-legs, flat-foot, chronic osteitis of the knee-joint, and spinal orthropathies. Each and every one of these is handled in a masterly manner, and the article on club-foot is, possibly, the most complete one extant. All of this work is very instructive because it presents unbiased and exhaustive considerations of the subjects treated. By the publication of this collection much has been rescued from obscurity.

THE GOSPEL ACCORDING TO DARWIN. By WOODS HUTCHINSON, A.M., M.D. Chicago: The Open Court Publishing Company, 1898.

IT is needless to say that Dr. Hutchinson's book is interesting. Any one who has read other of his writings, or has heard him talk, can well realize that he has attempted to find in modern science a basis and a satisfaction for certain of the tendencies in man that constitute natural religion apart from anything revealed. The attempt has sometimes brought him into outspoken opposition with religious dogma in its strictest sense. The style is not, however, in any sense controversial, and the material is handled in a way to make it eminently suggestive. Dogmatists will find it heretical, materialists will think it not progressive enough or at least over-sentimental, while pure scientists, *i.e.*, men who cultivate science heedless, if possible, of any relations it may have with the non-material, will perhaps resent the application of their scientific discoveries to an order of truth to which they are not related. Meantime, to ordinary medical readers it will prove without doubt a well spring of serious thought on the questions in which religion and science touch each other.

Some of the chapters, as that on "The Value of Pain," containing under subheadings the discussion of such interesting subjects as "Pain Necessary to Life and Progress," "Value of Pain in Disease," "Discomfort as a Factor in Progress," "Discomfort the Mother of Science," are especially suggestive to the thinking medical man.

The chapter of excursion into sociological subjects, "The Duty and Glory of Reproduction and Economics of Prostitution," is extremely timely now that these questions have come to occupy so much of sincere scientific medical attention. The subheads, "Ignorance of Our Sexual Functions Immoral," and "Evil Effects of Limiting Size of Families," shows the thoroughly conservative yet eminently reasonable position the author takes on certain important living issues. Prostitution is handled from some points of view that are new and striking, especially for medical men, and some of the lines of thought are developments of opinions expressed by Dr. Hutchinson in the MEDICAL NEWS during the course of the past year.

Among the striking, because to all seeming utterly paradoxical, chapters is the one on "The Beauty of Death," in which the discussion of "Death as a Factor in Progress," "Dependence of Life on Death," and the "Painlessness of Death," redeems the precious character of the beautiful twin brother of sleep from the aspersions so usually cast upon it.

On the whole, the book is well worth the reading. In addition to conveying a lot of interesting scientific information pleasantly it will suggest fruitful lines of thought more precious than any merely new ideas.

A MANUAL OF VENEREAL DISEASES. By JAMES R. HAYDEN, M.D., Chief of Clinic and Instructor in Genito-Urinary and Venereal Diseases, College of Physicians and Surgeons, New York; Professor of Genito-Urinary and Venereal Diseases in the Medical Department of the University of Vermont, Etc. New (2d.) edition, revised and enlarged. New York and Philadelphia: Lea Brothers & Co., 1898.

THE new edition of Hayden's manual has been carefully revised, especially in the discussion of gonorrhea and chancroid. The chapters on gonorrhea and its complications present the subject in a very practical way, at the same time being correct in all scientific details. We believe that a mistake was made in neglecting to insert a statement as to the decolorization of the gonococci in the Gram procedure as that now seems to be firmly fixed as a means for differentiating the organism. There have been numerous additions under the head of gonorrhea; seminal vesiculitis, urethral cystitis, and cystitis are discussed, and a good description is given of the symptomatology and treatment of gonorrheal ophthalmia and gonorrheal rheumatism. Conservative treatment of gonorrhea is advised.

In the chapters on strictures, short articles have been added on the extravasation of urine and the care of urethral instruments. The methods of performing external urethrotomy are given in some detail. The articles on chancroid and syphilis have been brought up to date, although there are no striking changes. It is unusual to find in a book of even larger dimensions so complete a summary of the manifold phases of syphilitic infection as is here given.

The new manual will, undoubtedly, meet as great a success as its predecessor, especially because of its practical spirit.

THERAPEUTIC HINTS.

For Migraine, when associated with gout or rheumatism, the following pill is recommended:

℞	Quininæ valerianatis		gr. xv
	Ext. colchici	aa	gr. iv
	Ext. digitalis		
	Ext. aconiti		gr. ii.

M. Ft. pil. No. X. Sig: One pill at night after dinner.—*Hirtz.*

A Diaphoretic in Nephritis, when uremia is imminent:

℞	Pilocarpinæ hydrochloratis		gr. ⅙
	Mucilag. acaciæ		ʒ iii.

M. Sig. Three to six tablespoonfuls a day.

Although the dose is small, the drug thus given will stimulate perspiration while causing no unpleasant symptoms.—*Lemoine.*

To Anesthetize the Membrana Tympani.—

℞	Ac. carbolici pur.		
	Menthol	aa	gr. xv.
	Cocain hydrochlorat.		

M. Sig. External use.

BONAIN of Brest makes use of this mixture, which is a clear syrupy liquid, in the following manner: A small bit of absorbent cotton on a stylet is dipped in it and laid against the membrane, which is viewed through a speculum. A slight burning sensation is produced, but in two or three minutes the local anesthesia is complete, and an incision can be made painlessly. The mixture acts to some degree also as a caustic, as is evinced by a slight reddening of the membrane.

For Chronic Nephritis.—

℞	Lithii benzoat.	ʒ iiss
	Betol	gr. lxxx
	Sodii bicarb.	ʒ i.

M. Div. in chart No. XX. Sig. One powder two or three times a day between meals in cachets.

When the urine is diminished in quantity, dark in color, or possibly blood-stained, tannin should be prescribed as follows:

℞	Ac. tannici	aa	ʒ iiss.
	Pulv. cinchonæ		

M. Div. in Chart No. XX. Sig. One powder in a cachet twice a day at meal times.

This treatment is to be carried out for a considerable period. It is well to discontinue it during one week of each month.—*Lemoine.*

For Epilepsy.—

℞	Potassii iodi		ʒ i
	Potassii bromidi		ʒ ii
	Ammonii bromidi		ʒ iiss
	Potassii bicarbonatis		gr. xl
	Inf. calumbæ	q. s. ad.	ʒ vi.

M. Sig. One teaspoonful before each meal and three teaspoonfuls at bedtime, in a little water.—*Brown-Séquard.*

ORIGINAL ARTICLES.

THE CLINICAL EFFECT OF THYROID EXTRACT UPON FIBROID TUMORS OF THE UTERUS.[1]

BY WM. M. POLK, M.D.,
OF NEW YORK.

IT is gratifying to know that among the many benefits attributed to thyroid extract, gynecology has not been overlooked. Amenorrhea, as a part of obesity, is already known to be amenable to it, and now fibroids are to be brought under its influence. The observers chiefly concerned in this endeavor are Jouin, Bell, and Stedman, Jouin being first and the most conclusive. His earlier paper appeared in 1895; the second, a year later, the observations covering twenty-five cases. Stedman, December 18, 1896, presents one undoubted case; while Bell, May 14, 1896, experimenting upon fibroids with an extract from the mammary gland, merely makes the assertion that fibroids are benefited by thyroid extract. It is evident, therefore, that the question is old enough and sufficiently well presented to warrant close inquiry on our part.

To arrive at more definite knowledge as to what the remedy really accomplishes for uterine fibroids, let me now give you a synopsis of results in ten cases which have come under my observation during the last fourteen months.

CASE I.—Patient, aged forty years; single. First intimation of the disease was menorrhagia. This began at thirty-four, and in spite of the use of electricity and ergot for three years to the fullest extent bearable (the ergot to the production of physiological effects three weeks out of each month; the electricity three times a week for six months each year excepting a week allowed for menstruation) the disease steadily progressed. In October, 1896, the tumor filled the anterior half of the pelvis and was specially marked by two subserous growths, one estimated at the size of the first phalanx of the index-finger and the other that of the thumb (allowing for the thickness of the abdominal walls), the former projecting from the fundus toward the left pubic spine, the latter from the region of the right cornua toward the right inguinal region resting over the brim of the pelvis near the corresponding pectineal eminence.

Prior to each menstruation, the mass as a whole was larger and the abdominal distention was decidedly increased. About once a month, generally midway between the menstrual periods, there came a marked accession of pain at which time the subserous projections above named were very sensitive. Naturally, the excessive menorrhagia caused persistent anemia with disarrangement of most of the digestive functions excepting the regularity of intestinal movement. This was daily sufficient. The condition of the skin, hair, and nails was impaired as might also have been expected. On November 4, 1896, the patient began the use of thyroid extract and continued it until November 9, 1897. An examination on the latter date showed a reduction in the uterine mass of about one-fourth, this being well assured in the two projections above described. The reduction is reflected in the diminution of the abdomen as a whole and is particularly well-marked, by contrast, just before menstruation, there being no longer increased distention at such times. The pain and tenderness have practically disappeared and the mass has softened. Menstruation has assumed proportions but little in excess of the normal standard. There has been slight increase in weight. The skin has assumed its former rosy tint, its softness, and its normal standard of secretion. New hair has sprung up and the old regained its luster and the same ratio of betterment is shown by the nails. The muscles, nervous energy, and strength have risen from decided depression to about their normal state, so that taken all in all the patient considers herself a well women, and conducts her life in accordance with this idea.

July 1, 1898, condition of general health as good as on November 9, 1897, but the tumor shows a slight increase above that observed just prior to the commencement of the thyroid treatment. The menstrual flow has been a little in excess of the normal since April. Thyroid has not been given since February 1st, owing to tachycardia. Thyroid treatment recommenced June 20th.

CASE II.—Patient, aged thirty years; unmarried. Observation began October 1, 1896. Menstruation excessive since the 19th of September. Had been treated with ergot and the curette. Was very anemic, with all that the condition implies. Under ether she was found to have an interstitial growth about as large as a pigeon's egg, located on the right side of the uterus and apparently extending between the folds of the broad ligament. The menstrual flow as profuse as ever. Was again curetted and put on ergot to the physiological effect. Third menstrual period after the curettage was as profuse as ever. Thyroid now administered, May 1, 1897. Examined October 15, 1897. Tumor less prominent and uterus, as a whole, somewhat smaller than on May 1st. Menstruation about normal. No longer an anemic, feels well. June 1, 1898, general improvement continues,

[1] Read in part before the Baltimore Obstetrical Society, December, 1897. Additional observations in December, 1898.

but growth is about as large as at first observation, and for the past three months, menstruation was in excess.

CASE III.—Patient, aged thirty-five years; married; two children. Two years ago menstruation began to be profuse and painful. Has emaciated slightly and is always conscious of fulness and weight in the pelvis, most marked just prior to menstruation. Examination shows a symmetrically enlarged uterus, size about equal to a four-months' pregnancy. The growth appeared to be wholly interstitial. This patient was subjected to treatment by ergot and electricity for four months, without apparent result. Was then put upon thyroid extract for four months. The result was a disappearance of pain and fulness, a practically normal menstruation, and the same marked general improvement noted in Case I. The tumor was softened and had apparently lessened in size. July 1, 1898, this improvement continues.

CASE IV.—Patient aged thirty-nine years; single. Gradual enlargement of abdomen for last nine years. Four years ago first realized that this enlargement meant a tumor. Being a busy, active woman, suppressed her discomfort until about a year ago when it became so severe as to be unbearable. Walking, turning in bed, and finally, even breathing was painful, and a sudden jar was most distressing. This pain was diffused more or less over the entire abdomen. She menstruated excessively eight days. The tumor was quite as large as a pregnant uterus at term; was sensitive and symmetrical. After five-months' use of thyroid extract she was one inch less in size of abdomen, quite comfortable, free from the former pain, menstruated five days naturally, and felt strong and well, all of which is borne out by the decided improvement in her general appearance. March 18, 1898, improvement is maintained.

CASES V. AND VI.—Patients have growths similar in many respects, although the first is forty-two years old, is married and the mother of one child eighteen years old. The second is single, aged thirty-four. Both have had menorrhagia for about six years; both have probably the myomatous form of growth, the tumor in each case being smooth, symmetrical, comparatively soft, and about as large as a four-months' pregnancy. Each has taken the remedy ten months, with betterment of general health and apparent arrest of growth, it being in each about the size found on first examination. In Case V. menstruation was arrested for three months, when it came on excessively and has returned each month, still in excess but less than before taking the remedy. She has suffered some loss of flesh. The other patient has found decided betterment of general health and energy but the menorrhagia is no better. I am now inclined to consider this case as one of submucous sessile growth. A recapitulation of the net result in these two cases is to the effect that the flow has not been materially lessened; the tumors have not grown; the general health has improved. July 1, 1898, the flow has been controlled in both. The tumors are smaller, the general health is excellent.

In Case VII. we scored a failure, as the medicine caused too much gastric disturbance. The patient, however, was timid, or rather had timid surroundings, and these proved too formidable, so the remedy was stopped at the end of two weeks.

CASE VIII. — Patient, aged thirty-eight years; married; two children, youngest eleven years old. First observation September 16, 1897. Uterus about size of the second month of pregnancy. It was hard, with here and there small interstitial nodules. Menstruated in excess, the flow lasting four days beyond the normal. (This had been the condition for years.) Thyroid commenced at above date. The next menstruation was nearly normal. General health showed improvement. The succeeding menstruation absent. Condition of general improvement still more marked. May 1, 1898, the amenorrhea had been shown to be due to pregnancy, this condition dating from the period of November, 1897. Confined of a living child August, 1898.

CASE IX.—Patient aged thirty-four; single. October 6, 1897. For two years had menstruated in excess, and had suffered from pain in the left iliac region which, upon examination, was found to be seated in a subperitoneal fibroid excrescence situated upon the left side of the uterus. The uterus was nodular, showing several nodules, the whole about the size of a three-months' pregnant uterus. After six-weeks' use of the remedy the pain and tenderness were lessened, and the flow was decreased at the last period. Up to May 1, 1898, this improvement had been maintained. The patient is able to follow her vocation as nurse without let or hindrance.

CASE X.—Patient, aged forty years; married. First observation April 10, 1897. Has two children, the youngest ten years old. For the last five years had had menorrhagia which had finally become so profuse as to impair her efficiency as a wife and housekeeper. Has a nodular, hard uterus, about equal in size to a pregnancy of four months. No special tenderness and but little local discomfort. This patient at the end of eight months gives the same favorable results noted in other cases: control of bleeding and improvement in general health. The tumor apparently is no larger than at the original observation. May 1, 1898: this same improvement maintained.

The net result in each case (Case VII. excepted) has been improvement, the greatest existing in those who took the treatment longest. Its manifestations were: (*a*) control of the menstrual flow; (*b*) arrest of the growth and, in some cases, diminution of the size of the tumor and apparently softening of it; (*c*) disappearance of pain and diminution of tenderness in the growth, and also of the sense of abdominal and pelvic distention, increase of muscular and nervous energy; (*d*) betterment of general nutrition, manifested at first by slight loss and then by return of flesh; improved state of the skin, hair, and nails, and in the substitution of a good color for the ap-

pearance of anemia. As might be inferred, the condition of the bowels was likewise improved although, as we shall see later, this was counterbalanced in some cases by gastric disturbances. It must not be supposed, however, that this was the sole drawback. There were others, but none was insurmountable —all belonged to the state now designated "thyroidism," but were manifested in its milder form because of the close watch kept upon the remedy. In every instance tachycardia was the most common drawback; next, restlessness and sleeplessness, when the drug was taken at bedtime; and lastly, indigestion.

It is evident then, that the remedy is efficacious, but when conceded a place, it must be compared with those accepted and now in use. To this end we, therefore, submit the following observations: Ergot, with or without digitalis, has failed to arrest menorrhagia in about fifty per cent. of our cases, and when successful it has been continued, as a rule, in the face of an impairment of digestion and bowel action, interference with the heart's action, and sometimes its use has been accompanied by a good deal of mental depression. Even though retarding growth for a time, it loses this action after a while. It aids in the expulsion of submucous fibroids and the conversion of interstitial into subperitoneal and submucous growths. The general health is apt to deteriorate much in the prolonged use of this drug. The suspension of the ergot has been followed usually by relapse into a state about as unfavorable as when it was commenced. Electricity has given little satisfaction, except when used as a cauterant to the mucous membrane of the uterus, and this action has appeared to be in no way superior to the use of the curette, and is more dangerous. Curettage involves anesthesia and invasion of the uterine cavity not once, but repeatedly in all cases. Ligation of the uterine arteries is an operation *sub judice*, our experience being against rather than in its favor. Removal of the ovaries is an operation which offers, perhaps, a better result than mere ligation of the uterine arteries, but it is an open question with many having a patient fitted for a laparotomy if total extirpation is not better. Myomectomy, either submucous or subperitoneal, and total extirpation are procedures which stand by themselves, facing no rivals in their appropriate fields, so no comparison with any medicinal or hygienic treatment can be instituted with them.

This, therefore, reduces the competitors of the thyroid treatment to the purely medicinal—such as ergot and digitalis—to electricity, and what may be called the palliative operations, such as curettage, ligation of the uterine arteries, and oöphorectomy. We recognize that it is premature to institute a comparison between this thyroid treatment and the so-called palliatives, yet we have ventured upon it for the sole reason that our individual experience has seemed to justify it. If, therefore, the thyroid treatment can be shown to possess the power to keep down the menorrhagia, metrorrhagia, and hydrorrhea of fibroids; if it can control their growth and annul the pain inherent to many of them it is superior to any medicinal treatment now in vogue; is better than electricity, curettage, or ligation of the uterine arteries; is preferable to oophorectomy, and in all smaller tumors it should be carefully employed before myomectomy or total ablation is resorted to, excepting, of course, cases in which the growth is merely submucous or in which malignant or septic changes are suspected. All such cases, in common with the larger growths, come within the pale of myomectomy or total ablation and, as already admitted, are outside the field of this comparison.

As to the possibility of an efficient combination of some one or more of these discredited agents or procedures with the thyroid treatment, it has appeared to me as probable that some cases might be best reached through some such combination, for instance, cases of excessive menorrhagia might do best with a preliminary destruction of the diseased mucous membrane with the curette, to be followed soon after by the thyroid treatment. Then again, in combination with ergot, the two to be given simultaneously or successively as the symptoms suggest or warrant. The preliminary use of the curette appeals to one in the class of cases mentioned, but cannot be suggested as a routine measure for the reason that we have found it unnecessary in two of our cases. The combination treatment with ergot has seemed beneficial when it is borne well, three patients having been so treated. After the suspension of the thyroid, these patients were placed on ergot and it appeared to us that the good effects of the thyroid were maintained the better. We had previously observed these patients about six months upon the thyroid alone, and subsequently made observations for the same period of this combined treatment. In two others we instituted similar observations, with the combination of thyroid and electricity, but cannot say that we are convinced as to its efficiency. We wish it to be understood that in using electricity we do not carry the pole beyond the cervical canal, our experience with its intra-uterine application, except under anesthesia, having shown that we were apt to set up an intra-uterine septic inflammation, an accident only too sure to occur in the absence of the kind of antiseptic technic which is necessary, and possible, only under anesthesia.

As yet we have not been able to determine which of the two classes of fibroids are most amenable to the thyroid treatment, but we incline to the belief that the nearer the growth approaches the type of the pure myoma, as distinct from the fibromyoma, the better the ultimate result with the treatment. The bleeding, however, is more quickly controlled in the fibromyomas. This much one would infer from the comparative bloodlessness of this type, and yet, while leaning toward favorable conclusions, we must not forget that the effect of the long-continued use of this remedy in these cases is undetermined. We know of the more acute effects, *viz.:* the headaches, tremors, gouty and rheumatic pains, general debility, persistent vomiting, and profuse diarrhea; the tachycardia with its dyspnea, perhaps, even fatal, we know of, but we do not know how easily these symptoms are controlled by regulating the dosage or stopping the remedy. But have we information of some possible general, degenerative change in consequence of prolonged use? For answer, we are forced to consult myxedemas, for they are the only cases which, so far, have been long exposed to the drug. It is true that here we have a disease clearly due to a thyrosis, and in giving the drug we merely return that which Nature requires, so it is fair to assume that nothing but good can come to myxedema from proper dosage with the thyroid. But so far as fibroids are concerned we must remain in uncertainty upon this point until the condition of the thyroid gland and secretion can be determined. Until such information is forthcoming we must get our encouragement from analogy. Both diseases are common to women and common at about the same period, both are characterized largely by an increase of the connective-tissue elements, and both are prone to uterine bleedings. This similarity is too general to be more than suggestive, particularly when it is offset by the dominating influence of the ovary whose removal generally determines the subsidence of fibro-uterine disease. But in the absence of any contraindication the analogy may be taken as a justification for the prolonged use of thyroid extract in this disease, with the proviso that we be alert, be keenly inquisitive as to the state of the circulatory, renal, nervous, and digestive systems, stopping or curtailing treatment as warnings arise.

It may not be out of place to suggest a minimum meat diet for these patients, and to advise rest—rest even in bed when the tachycardia is too persistent and troublesome—or a change of preparation, as some have more of this poisonous action than others, probably due to impurities, such as ptomains, leucomains, or the substitution now and then of iodothysine, using the two alternately.

This paper, down to the sentence just closed, was read before the Baltimore Obstetrical Society, December 5, 1897. Since that date we have had an opportunity to add to our experience further observations upon the cases cited above. The most important relates to the effects of the prolonged use of the drug. All of these patients have now been subjected to this treatment more than a year, which is a period of time sufficient to give valuable if not conclusive evidence. Every patient showed diminution of body weight at first, Case II. more markedly than the others, but in none was it excessive, and in all a point was soon reached at which the general health showed decided improvement with a return of some of this loss. One patient showed such an increase of weight for a time that we were doubtful whether this was purely normal or a condition of pseudomyxedema, such as was witnessed about the face in certain cases of insanity reported by Berkley in the *Johns Hopkins Hospital Bulletin*, July, 1897.

Further observations, however, proved that the appearance and the increase of weight was due to changes upon normal lines. No other patient showed any tendency to this psuedomyxedema. The tachycardia has been the most troublesome symptom of all but in none has it been excessive. Of late, we have been combining arsenic (after Bedord and Mabille) and the extract of thymus gland, suggested by Zaibisse, as a means of controlling the thyroidism, but too little time has elapsed to warrant any conclusive statements. Fowler's solution is used, three drops three times a day and the thymus extract just double in dosage of the thyroid, the three agents being given simultaneously. An important addition has been made, however, from observations touching the condition of the uterus and tumors in consequence of prolongation of the treatment. The shrinkage and apparent arrest of growth noted during the earlier treatment has not been maintained in two of the cases, I. and II. Both of these are fibroid myomas, and both show now after twenty-months' treatment an increase in the size of the growth. The increase may be approximately stated as equal to about one-fourth of the size present at the initiation of the treatment. The control of bleeding, however, and the improved health has been maintained; so that we see no reason to retract what was said in December last touching the relative value of this treatment. The occurrence of pregnancy in Case VIII. is suggestive and, taken in connection with the evident action of the remedy upon the endometrium, as witnessed in the control of the bleeding, it points to a beneficent action in cases of sterility due to abnormal states of this membrane. It is surely worth a trial in every

such case, no contraindication existing elsewhere, as in the heart, for instance. Upon the question of contraindication we can say no more than urge caution in all cases. Arterial fibrosis and cardiac and renal disease forbid its use, but even then we feel disposed to advise its use with extra precaution against the accidents of the remedy.

In is interesting to note that at the last meeting of the American Gynecological Society, Boston, May 24, 1898, Mosely, Mann, Duer, McLane, and Fry all reported favorably upon the action of the remedy in this disease. While, therefore, giving full credence to the observations of Cunningham, which tend to the conclusion that "thyroidism" is the product of decomposed animal matter in the thyroid mixtures and tablets in common use and not to the essential thyroid secretion itself, we must still believe that the remedy, in addition to the poisonous action, possesses a beneficent influence upon fibroid tumors. Completed with this question is the influence of the substance in delivering pregnancy and its action upon peri- and para-uterine exudates, as well as the betterment of the general health in certain women long depressed by the influence of certain uterine and ovarian disorders, the sequence of inflammation.

In conclusion, we venture to append the following remarkable report, not because of the result reported but as additional evidence upon the question of prolonged use of the remedy:

Recurrent Carcinoma of the Female Breast Entirely Disappearing under the Persistent Use of Thyroid Extract Continued for Eighteen Months. By Frederick Page, M.D., Edin.; M.R.C.S., Eng.; and William Bishop, M.B., B.S., Durh. — *Lancet*, May 28, 1898.

In December, 1895, Mr. Page was asked by a former house-surgeon of his, Dr. Bishop, to see with him a woman, aged sixty-one, who was suffering from carcinoma of the left breast of some six-months' duration. Her general health was very much impaired. The growth was the size of a hen's egg, in the upper part of the breast. Both axillary glands and their lymphatics were affected. On January 7, 1896, the breast was removed, together with the axillary glands and fat, the lymphatics, and the pectoral fascia. In April there was a recurrence of the disease in the neighborhood of the cicatrix, and on July 18th, several small nodules were removed. Both specimens were examined and pronounced to be carcinomatous. In September, 1896, at the suggestion of Dr. Bishop, thyroid extract was given, quite as a forlorn hope. At first three grains were taken daily, and the dose gradually increased until fifteen grains could be taken daily. During the eighteen months that the drug was administered, it was necessary to occasionally suspend treatment on account of its toxic effect. The patient is now quite well, and no trace of the disease discovered.

A Christian Scientist Suicide.—John A. Leverens, a Christian Scientist of Detroit, shot himself through the brain and breast. Fear of insanity, it is believed, caused him to commit the act.

DISLOCATION OF THE SEMILUNAR CARTILAGE.[1]

By JOHN B. WALKER, M.D.,
OF NEW YORK;
ASSISTANT-SURGEON TO THE NEW YORK CANCER HOSPITAL; ASSISTANT INSTRUCTOR IN OPERATIVE SURGERY IN COLUMBIA UNIVERSITY.

IN these days of frequent football games one hears more often of injuries to the knee-joint, and in looking over the literature of this subject and in studying the cases, one is somewhat reminded of the injuries of the abdomen, for the more one investigates, the larger the field is found for operation. Formerly the peritoneal cavity was opened only in extreme cases; now it is opened not only for definite operations but also for the purpose of exploration in certain cases which are difficult of diagnosis. The knee-joint does not furnish as large a field as the abdomen, but more and more success has followed with the increasing number of operations. This advance in both classes of cases has been due to an improved technic aided by better asepsis. Both the the peritoneum and the synovial membrane are richly supplied with blood-vessels, and while these are capable of rapid absorption if pathogenic bacteria are present, yet if these can be excluded, as they generally are, conditions are present which are most favorable for prompt repair. The study of injuries to the knee is a most interesting one but also a broad one, so I shall confine this paper merely to that class which will be illustrated by the cases to be narrated later and which was first described by Hey, in 1803, as internal derangements of the knee-joint.

In order to better understand the function of the knee-joint it may be well to consider the anatomy of the parts. The semilunar cartilages are two crescentic fibro-cartilaginous plates which are attached to the oute margins of the head of the tibia. They are wedge-shaped, concave above, flat below, their outer borders being thick, firm, and adherent to the tibia, while the inner edge is thin, concave and quite freely movable on the head of the tibia. Anteriorly their tips are firmly implanted in a depression before the spine of the tibia, while posteriorly they are attached behind the spine. Their union is strengthened anteriorly by the fibers of the transverse ligament, the external, thicker, more circular, and covering a larger area being more strongly attached than the internal, which is thinner, more semicircular, somewhat elongated, and so less firmly adherent to the tibia. This fact may account for its more frequent separation and dislocation. Their function is to diminish the shock and jar of excessive motion in walking, run-

[1] Read before the Harvard Medical Society of New York, November 26, 1898.

ning, etc., and also to act as a support and guard to the condyles of the femur by means of their upper concave surface, through which they deepen the concavity of the articulation, thus adapting the surface of the tibia to the shape of the femur in its various positions between complete extension and flexion. The semilunar fibrocartilages being loosely attached to the head of the tibia, move forward in extension and backward in flexion of the joint, and further, as the condyles rolling upon the tibia present successively to the condylar surfaces of that bone portions having different curvatures, each cartilage, like a movable wedge, is contracted round the condyle during flexion of the joint and expanded during extension.

At first the knee-joint resembles a hinge-joint, but closer observation indicates that the movement consists rather of a combination of rolling, gliding, and rotation. The tibia executes a rotary movement during flexion around an imaginary axis drawn transversely through its upper end. Thus in extreme extension, it is the anterior portion of the tibia which is in contact with the femur; in the semiflexed position, its middle; in complete flexion, its posterior edge. As the condyles glide over the tibia they also rotate slowly and, as this rotation is made under pressure, a great strain is brought to bear upon the semilunar cartilage, so much so in fact, that one might expect separation to occur more frequently.

König believes that it is due to some antecedent disease, as tuberculosis or osteochondritis desiccans, but it is maintained by others that although tuberculosis of the knee-joint is quite common, yet the separation of the cartilage is not found any more frequently in this disease than when it has not existed. However, in cases in which this disease has existed, it may be considered as a predisposing factor, for the ligaments may have become weakened and lax so that the joint is not as strongly supported. In such a case a strain which could be well sustained by a normal joint might, in this relaxed condition produce a rupture of the cartilage. Shaffer has reported a number of cases in which he found, "elongated ligamentum patellar together with a very considerable lateral mobility of the joint."

Undoubtedly the largest number of cases are due to trauma. Some few patients furnish a history of direct injury to the joint, the person having fallen and struck the knee directly, and as a result of this contusion inflammatory processes may have developed, which finally terminated in the separation of a portion of the cartilage. This class is small and the majority of cases have arisen without the association of great force. The injury is due to some sudden and almost involuntary movement when the muscles governing the joint are off their guard. The patient slips and in falling forward the knee is usually semiflexed; there is a rotatory movement of the leg outward, or if the leg be fixed, a rotation of the thigh inward. Thus a great strain is exerted, usually upon the internal cartilage. It sustains a certain amount of strain and then gives way; it may be separated merely along its middle portion from its attachment to the tibia, or it may be ruptured anywhere in its course; or it may be torn away from its anterior attachment to the tibia. Again it may be due to forcible movements, that is, bending the knee beyond its usual range of motion together with a twisting motion.

Barker has described the mechanism of the accident as follows: "The actual dislocation is due to the nipping of its edge when the limb is extending, which fixes it between the two bones and prevents it traveling forward while the capsule, being rendered tense by extension, is torn away from it more and more until there is nothing to prevent it slipping into the middle of the joint." It occurs most often in young, active males between the ages of twenty and forty years, rarely ever in females. The internal cartilage is the one usually affected.

Diagnosis.—This is oftentimes difficult and sometimes very uncertain and it will depend much upon whether the case is a recent, or an old one. If a good history can be obtained it will be of the greatest assistance. In a recent case one hears that the accident happened for the first time while walking or running; the foot slipped and the leg was twisted while in a semiflexed position. The pain is sudden and severe; generally the most sensitive area is over the internal cartilage, and sometimes when the cartilage is much displaced it may be felt to move underneath the area of this greatest pain. Some few have found a depression in this area, but this observation has been uncommon. If, however, the case is an old one, and this has been true in the majority of reported cases, one may obtain a history of several previous recurring attacks each one of which has been similar but a little more severe than the preceding one. The attacks will have been more painful and the period of recovery prolonged. It will be learned that the knee has repeatedly given way without much strain having been applied, and that the patient has lost confidence in its strength, and can only use the knee when it is steadied and supported by some form of apparatus. The joint will have become so much swollen and the tissues so thickened from the recurrent attacks of synovitis that the normal outline cannot be defined. It will be necessary to wait until the effusion has subsided before locating the displaced cartilage. This has

been the experience of Barker, MacCormac, and Bull. Generally the leg cannot be extended without considerable manipulation to first express the cartilage from between the condyles and the head of the tibia. This may also be true when one has to deal with a floating cartilage; in the later case, however, the floating cartilage may often be worked to the outer aspect of the tibia, where it can be felt to move underneath the finger. The floating cartilage has much the greater range of motion. Moreover in all the reported cases it has been the internal semilunar cartilage which has been separated or dislocated.

Treatment.—This may be considered under two heads, non-operative and operative. Occasionally one may he able to see the patient shortly after the accident has occurred for the first time. After the preliminary examination an attempt will be made to replace the dislocated cartilage, and this may be accomplished by flexing the leg as much as possible on the thigh, then rotating the tibia inward, if it is the internal cartilage; or outward, if it is the external cartilage that has been displaced, and next extending the leg quickly upon the thigh while pressing with the thumb where the cartilage is supposed to be out of place. A firm bandage is then carefully applied and a pad adjusted over the displaced part. The patient is confined to bed and an ice-cap placed over the knee. On the following day massage is begun and continued daily. Graham suggests massage as being useful for two purposes: first, considering that possibly this accident may have occurred because of a lax condition of the ligaments and muscles of the knee, which involve a previous synovitis, or from a generally relaxed condition, the massage would improve the condition; second, after an accident similar to this there is always a certain amount of effusion, and for the removal of this massage is especially indicated. He narrates several instances in which he had treated the patients successfully in this way, and states that they were able to go about after a couple of months without any apparatus or other artificial support. As a precautionary measure it is suggested that the patient walk with the toes turned inward when there has been trouble with the internal cartilage, and with them turned outward when the trouble has been with the external cartilage.

Shaffer has published reports of several interesting cases, perhaps of a little severer type, in which he has succeeded very well by the use of his so-called Campbell knee apparatus. Thus, it may be said that with both the massage and the apparatus, patients who suffer from the milder types may go about their business in comfort without an operation. It may be necessary to wear the apparatus for several months, or an indefinite time, and one can never be sure that if he leaves off the apparatus the trouble may not return. That this may be so has been admitted by both these writers.

In the majority of cases these methods will not succeed, and it will become necessary to open the joint. It is the belief of the writer that under suitable conditions this can be done without much danger. In regard to the operation two incisions may be considered: first (Barker's method), with the leg extended a curved incision is made from the inner border of the ligament of the patella to the anterior edge of the lateral ligament. The ends of the incision in all cases correspond to a line a little above the line of the head of the tibia. The convexity of the flap reaches down about an inch on the head of the latter. The periosteum is raised with the flap which contains the capsule besides, but the fibers are left intact in their relation to the periosteum. This is necessary for the subsequent strength of the joint. When this flap is raised the cartilaginous rim of the articular facet is generally to be seen divested of its covering of semilunar cartilage, which sometimes may be seen separated, or at other times it is twisted or curved up, its end being drawn to the interior of the joint. This incision certainly easily exposes the entire line of articulation. It has, however, the disadvantage of cutting the capsule transversely and thus weakening it so that some operators prefer to make a vertical incision, as recommended by Allingham and MacCormac. This should be three to four inches in length in the long axis of the leg and three quarters or so internal to the patella, its center corresponding to the line of the joint. In regard to the position of the limb, there is more room in the flexed position, though either that or the extended one may be adopted. If possible the limb should be maintained throughout in one position to prevent blood from getting into the cavity. The structures from the skin to the synovial membrane should be divided in turn until the division of the capsule exposes the synovial membrane clearly at the bottom of the wound. All the superficial structures should be divided throughout the whole length of the wound, and only after all bleeding-points have been secured should the synovial membrane be opened. The cartilage may now come into view. One may proceed now in one of two ways, either suture, or excise and remove the cartilage. In mild cases the cartilage may simply be separated from its attachment to the head of the tibia, but it still may remain attached by its two extremities. In such cases Barker has been very successful by his method of suture. Two or more sutures of silk are passed through the fibrous invest-

ment covering the tuberosity of the tibia, then through the cartilage, and tied. Silk should be preferred to gut as it is more reliable. If the cartilage be fully separated from either its anterior or posterior attachments, the coronary ligament torn through, and the cartilage curled up, it is better to excise it. When the knee is in a flexed position this is almost always the case.

Generally, when a patient comes to operation it is only after he has suffered from repeated, recurrent attacks, extending generally over some length of time, and in these cases one will find that the cartilage has not only become separated from the end of the tibia, but its anterior or forward end has been torn loose from its attachment, and it will be found twisted inward toward the middle of the joint, that is, the intercondyloid notch. In these cases one will only be able to pull the cartilage out into its former normal position by means of a hook, and with some considerable force. Even when replaced if it is released from the hook it will retract again into the middle of the joint. It would seem here that if the method of suture were used there would be considerable tension upon the sutures, and one could not but feel that perhaps the union might not be sufficiently firm between the separated portions so that should the knee be twisted the cartilage might again become dislocated, and for this reason it is suggested that the method of excision be employed for this class of cases. This procedure is recommended by Bull, MacCormac, and March. It is a more radical and a more certain method than that of suture, yet it might be open to the theoretical objection that the joint would not be as strong after the cartilage had been removed. It has been found by practical experience, however, that this weakening of the joint does not occur, and that the patients walk perfectly well. The cartilage should be cut away at the point where it is separated from the head of the tibia and the end bevelled off.

One has now to consider whether to irrigate the joint or not. In those cases in which there has not been much effusion, in which the joint has not been subjected to much manipulation during the operation, in which extensive dissection has not caused much hemorrhage into the joint, and in which no previous disease has existed, it is probably unnecessary to irrigate the joint. If, on the contrary, these conditions exist, it may be well to wash out the joint with normal salt solution. When there has been no irrigation the capsule can be entirely closed without drainage. The wound must be closed with great care, the synovial membrane, the capsule, and the exterior structures being sutured with fine catgut. The sutures should not be placed too close together, thus preventing the easy escape of fluid should effusion arise. A plaster-of-Paris bandage is next applied. At the end of seven days, when primary union has occurred, the dressing is removed and passive motion and massage is begun. In order to protect the joint and give the patient a feeling of security an apparatus may be worn and the patient allowed to move about. The prognosis is good, for, after a careful study of the literature covering the past five years, including about one hundred cases, there has not been found a reported case of death following these operations.

Through the courtesy of Dr. W. T. Bull I am able to report the following case in which I assisted at the operation:

Case I.—Male, aged twenty-one years. In the fall of 1892, while playing football he slipped, fell, and twisted his right knee. He felt something snap and give away. This was followed by an acute attack of synovitis, which confined him to bed about four weeks. One year later, while running he fell and twisted his knee again, and had considerable pain over the inner side of the joint. He could extend the leg only with difficulty and with much pain, and was confined to bed five weeks. He went about on crutches for three weeks, and later was obliged to wear a rubber knee-cap. Eight months later his knee gave away, he fell, and another attack of synovitis followed. Eighteen months later he again fell and twisted his knee, and was unable to extend his leg until after it had been manipulated. The physician in charge diagnosed a floating cartilage, an incision under cocain was made, but no cartilage was found. An apparatus was then applied, which immobilized his knee for several weeks so as to permit him to walk about. Six months later his last attack occurred, which was much more severe than any of the previous ones. After the effusion had subsided, it was possible at times to feel the dislocated cartilage at the inner side of the joint at the level of the articulation.

On February 15, 1897, he was operated upon under ether. A vertical incision four inches long was made on the inner side of the knee-joint, in front of the lateral ligament, midway between it and the inner border of the patella. The structures were carefully divided so that there was very little bleeding. On opening the capsule the internal semilunar cartilage was found to be absent from its normal position but it was easily recognized. Its tip had been torn away from its anterior insertion, and it was separated from its attachment to the head of the tibia for a distance of about two inches backward. Its tip was curled up and projected inward toward the center of the joint. This was drawn outward by means of a tenaculum and was cut away from the tibia at the point where the separation began, the stump being bevelled. The capsule was closed with catgut and the outer structures with silk, a small gauze drain leading down to the joint. A large sterile dressing, strengthened by a plaster-of-Paris

splint, was finally applied. The gauze drain was withdrawn at the end of seventy-two hours. Primary union resulted, passive motion and massage were begun within three weeks, and the patient walked at the end of four weeks. Eighteen months have elapsed since the operation without the recurrence of any further trouble, and the function of the joint is good. He went to the front in the recent war, and has been perfectly satisfied with the result of the operation.

As a matter of interest and for the purpose of further increasing the statistics, I add the following reports of cases:

CASE II.—By Dr. W. T. Bull. Male, thirty-five years of age. One year previously he slipped and twisted his left knee and was unable to extend the leg. Synovitis developed and his knee was confined in plaster of Paris for three months. During the previous three months, his knee-joint had been "locked" several times; it had been very painful, and had incapacitated him from his work. Moderate effusion was present, and an area of tenderness existed over the inner side of the joint. A transverse incision was made to expose the joint. The internal semilunar cartilage was seen to be separated and dislocated inward. It was excised, and the structures sutured as in the preceding case. Drainage was also used. The recovery was uneventful. He walked on the twenty-first day and at the end of a year was in excellent condition.

CASE III.—By Dr. W. T. Bull. Male, aged forty years. Four years previously he fell and struck on his left knee. Ever since he had had more or less pain on the inner side of the joint. It had been swollen and at times had been "locked," so that he had a constant feeling of insecurity. A vertical incision was made at the inner side of the joint, exposing the internal cartilage. It was separated and dislocated. It was excised and the joint drained as in the preceding cases. He walked with crutches on the twentieth day, and a year later was still in good condition.

CASE IV.—By Dr. V. P. Gibney. Male, aged nineteen years. Four years before he slipped and fell, twisting his left knee. Synovitis developed and left his knee somewhat weakened. He had had several recurrent attacks so that his knee remained more or less tender, especially over the inner side of the joint. Several months before he discovered a movable body, which slipped under his finger. A vertical incision was made, which revealed a dislocated semilunar cartilage. This was excised and the joint sutured without drainage. A plaster-of-Paris bandage was applied. Recovery was uneventful, and at the end of four weeks he walked without lameness.

CASE V.—By Dr. V. P. Gibney. Male, twenty-one years of age. Five years before, while playing tennis, he slipped and fell. There was considerable pain over the inner side of the right knee-joint. Synovitis developed. This recurred several times, leaving the knee weaker and more insecure. Several times he felt a movable body at the inner side of the knee. A vertical incision was made, which showed a portion of the right semilunar cartilage to be separated and dislocated. The end, which had become pedunculated, was excised, and the incision was closed without drainage. Recovery was uneventful.

CASE VI.—By Dr. V. P. Gibney. Male, twenty-two years old. During the previous three years he had had recurrent attacks of slipping, falling, and twisting of his right knee. Synovitis followed each time, so that when seen he suffered from subacute synovitis. A vertical incision exposed the joint, showing the right internal semilunar cartilage to be separated and its tip displaced inward. This was excised and the joint closed without drainage. Recovery was uneventful. One year later the patient reported his condition as being excellent.

DISCUSSION.

DR. BREWER said that the members of the society should be extremely grateful to Dr. Walker for his very practical exposition of this interesting question of loose cartilages in the knee-joint. He himself knows two or three patients who are almost helpless from this affection, one a young woman, who spends from one to three months in bed a couple of times a year or oftener with acute synovitis from this cause and whose life is made sadly miserable. Operation is usually not advised in these cases because it is not known that opinion is yet definitely settled as to the definite value of surgical interference or as to its justifiability except in extreme circumstances. He thinks that in the etiology of loose and displaced cartilages Dr. Shaffer's explanation adds an important element to previous theories. The cases in which displacement occurs are wobbly joints, in which all the ligamentous attachments around the joint are looser than normal. He has found this to be true in his own cases and has even been able to demonstrate by actual measurement that the patellar ligament was larger than normal.

He has seen some surprising spontaneous recoveries. In one case after three severe attacks each more bothersome than the preceding one he advised operation, but it was refused. Afterward there were three milder attacks all in the same leg, then a slight attack followed by a severer one in the other leg; yet with care and a sedentary occupation no further attacks occurred. It is now some three years since the last one and the patient made the campaign in Cuba with the Rough Riders during the late war and has returned absolutely without having had a symptom of knee-joint trouble while soldiering.

DR. BROWN said that his experience was mainly personal. Twice in football practice he has had the symptoms develop that are usually thought to indicate displaced cartilages in the knee-joint and yet has recovered perfectly and though that is now some time ago has had no bother since. He knows of a number of cases where the diagnosis of displaced cartilage was made and yet complete recovery has followed rest. He supposes, however, that these are the milder cases.

DR. FISKE thinks it scarcely justifiable to compare the knee-joint to the abdominal cavity, or to

suggest that an exploratory incision of the knee-joint should be made with practically as much freedom as an exploratory laparotomy. The lymphatic supply of the peritoneum is better, its vitality higher and it is better able to deal with infection. We can at present open the large joints with much more safety than we could some years ago but there must be a very serious reason for there is still great danger in the procedure. For loose cartilage, for instance, operation is indicated only after a thorough trial of conservative methods has failed. He thinks that Allingham's plan of suturing all the different planes of tissue above the joint as detailed by Dr. Walker is a good one. In the extraction of floating cartilage, however, when the object can be cut directly down upon or when it can be coaxed into a favorable position for removal, the small incision necessary may be simply closed with a piece of rubber tissue. He has seen this plan give excellent results in Dr. Abbe's hands in a number of cases.

DR. WILCOX said that from his personal experience he thinks he can say that a dislocation of the semilunar cartilages must not be frequent. On four different occasions he has had extremely bad wrenches of his knee. Considerable acute synovitis has always developed, but he has never had any subsequent symptoms pointing to loose or displaced cartilages.

DR. WALKER, in conclusion, said that not every case is suitable for operation but only the inveterate ones in which other methods have been tried and have failed. Certain patients seem to get entirely well under rest and apparatus. These are the ones in whom the middle of the cartilage is detached but not the ends. Reattachment takes place then rather readily under favorable conditions. It is true, doubtless, that the synovial membrane will not stand manipulation and infection quite so well as the peritoneum, but the fact remains that it will stand them much better than has been thought. In any operation for the condition there is always a certain element of exploration for a definite positive diagnosis before operation could be made with certainty but very rarely. In answer to the question if there is usually not a depression over the spot where the cartilage should be but is not, Dr. Walker said that usually in these patients when they come for treatment there is an effusion into the joint that obliterates the depression that would otherwise exist. In patients who come after the acute stage had passed there have usually been several attacks and so a chronic synovitis with a certain amount of persistent effusion existed to obscure the valuable symptom of depression.

In reply to a question as to the frequency of displaced cartilages he considered that his experience and knowledge of the literature on the subject enabled him to say positively that the affection is not frequent and it is even probable that some cases diagnosed as displaced semilunar cartilages are really only cases of acute traumatic synovitis.

FURUNCULOSIS; ITS ETIOLOGY AND TREATMENT.

BY H. H. STONER, M.D.,
OF ROCK RAPIDS, IOWA.

A SPECIAL notice of an apparently so insignificant and common affection as boils seems to be beneath the dignity of medical writers in general if the dearth of literature upon the subject may be taken as a criterion. The great variety of remedies that has been hurled against this ignoble visitant is proof to my mind that its etiology has not been as well understood as it might have been, hence, the profession is not agreed as to its best mode of treatment. While each remedy may meet with a certain amount of success, none of them will be found to be a specific. Among the many remedies employed may be mentioned poultices, arnica, asaprol, calcium sulphid, camphor, carbolic acid, colchicum, hypophospites, menthol, pyoctanin, sodium phosphate, turpentine, bichlorid of mercury, yeast, and a host of others.

Let us inquire into the cause of this provoking disorder and see if we cannot therefrom arrive at a more rational mode of treatment. I believe all will agree that suppuration is directly due to the presence of pus-producing organisms; that being the case it must necessarily follow that furuncles are caused by the same agency. The ubiquitous staphylococcus pyogenes aureus is the responsible organism in the great majority of cases, although the staphylococcus pyogenes albus and citreus may sometimes be found to be the cause.

Boils are not due to an internal dyscrasia. They are purely a local affection. It is true that in some conditions of disordered metabolism, such as diabetes, in which the resisting power of the tissues is diminished, the pyogenic cocci flourish in the form of furuncles, with but feeble opposition to their development. Barring such circumstances the condition of the system at large has nothing whatever to do with the development of this form of phlegmon. The germs gain access to the deeper parts of the skin through the avenues of the hair-shafts and sweat-glands. In the great majority of instances the hair-shafts furnish the most accessible route for their entrance, as may be demonstrated by observing in its incipiency the presence of a hair projecting from the apex of the inflamed and tender little elevation. The germs after gaining entrance to a hair-follicle rapidly multiply and the contiguous blood-vessels become engorged and finally occluded, with the result that the tissues in the immediate neighborhood become necrotic. The classical symptoms of inflam-

mation continue until the pus formed is evacuated, either by natural or artificial means, when if the necrosed portion has not already been liquefied it comes away in a mass. This is the core which is so often seen in this affection. The pus which escapes from the abscess is laden with micrococci and in this stage, at their height of activity, they are in their most virulent form and will readily inoculate any follicle with which they are allowed to come in contact. This is the time when the surgeon will be able to do most for his patient. I am convinced that there is no treatment that will abort a boil when it has once gotten thoroughly under way. I am certain, however, that a successive crop of boils can be prevented by very simple means. Furunculosis owes its etiology, as above intimated, to infection of neighboring follicles from the pus-producing organisms present in a pre-existing furuncle. The subject of this distressing ailment is prone to handle and fuss with it, with the result that the germs become deposited upon his fingers and beneath his nails. By this means they are readily conveyed to remote parts of the body by the act of scratching. Probably the most fruitful source of infection is through contamination of the clothing worn by the patient. An individual suffering from a small furuncle which scarcely causes enough uneasiness to attract his attention allows it to point and break without any care upon his part. The consequence is the pus-cocci are deposited upon his undergarments and a number of local points of infection develop upon the body which has come in contact with the infected clothing. The bedclothing may be in like manner contaminated, producing infection in distant parts of the body; or if the abscess contains a greater amount of pus at the time when it breaks the pus may run in a stream for a certain distance along the skin infecting every follicle in its path. Such is the history of small furuncles. Larger ones which demand the attention of the patient fare but little better. They are usually poulticed, with the result that the heat and moisture enhance the vitality and activity of the pyogenic organisms, and a greater amount of necrotic tissue is produced, so that the temporary alleviation of the pain due to poulticing is more than counterbalanced by the evil it produces. In this form the abscess is usually treated by covering it with a light dressing, but no care is taken to prevent the disease-producing germs from coming in contact with the contiguous surfaces of the skin, hence, several abscesses of varying degrees of severity are liable to develop in close proximity.

I mention the theory of the transmission of pyogenic germs to distant parts through the medium of the lymphatics only to dismiss it, as I am satisfied from observation that an overwhelming majority of cases may be traced to the source above described. If the theory I have outlined is based upon sound principles, and I believe every careful observer will agree with me that it is, the rational treatment of furunculosis should consist in confining the germs within their original abode. How thoroughly this precaution may be carried out will depend much upon the care and intelligence of the patient, and much upon the location of the furuncle. Patients suffering from this disease are seldom confined to bed and are more or less active. There is frequently found certain locations upon the body where it is well nigh impossible to so adjust a dressing as to preclude the possibility of the surrounding parts being constantly bathed with the exuding pus. Here the local application of antiseptics stands first and foremost among measures intended to frustrate the infection of contiguous tissues. Bichlorid of mercury in strong solution, 1 to 500, far transcends any other antiseptic. It should be mopped upon the unbroken skin for some distance about the abscess. The limits of the area to be so bathed will depend upon the amount of pus escaping and the facility with which it can be absorbed by the dressing and confined to the immediate region of the abscess. Such an application should be made twice each day. The abscess cavity should be carefully irrigated with a weak bichlorid solution. A piece of soft lint should be moistened with the solution, 1 to 2000, and laid upon it, over which should be placed a sufficient amount of absorbent cotton to absorb the discharge. Over this, if possible, should be applied a well-fitting bandage. If the patient himself attends to the dressing he should be taught to carefully disinfect his hands afterward. By following out this line of treatment the condition of so-called furunculosis will disappear with the healing of the original points of infection.

As to the abortive treatment of an individual abscess I have stated above that we are not in possession of any remedy capable of exerting such a happy effect. Carbolic acid, by injecting into the substance of the boil, has been more extensively employed than any other remedy, but that it as often meets with failure as with success will be attested by every surgeon who has given it a fair trial. The passage of a needle into an inflamed and highly sensitive furuncle is painful in the extreme and most patients would prefer to let it pursue its natural course rather than be subjected to several such injections with the hope but not assurance of its abortion. Bichlorid of mercury, in 1 to 500 solution, diligently applied, will be found to be equally if not more successful. It has the further advantage that its application is not pain-

ful. Cases will many times be encountered in which the original point of infection has not been properly cared for during or after its eruption. Scattered round about this mother boil will be seen numerous small fledglings in various degrees of incipiency which if left untreated will bloom into full-fledged boils. Here the so-called abortive treatment possesses much efficacy. If the strong solution of bichlorid is thoroughly mopped upon these minute points of infection it will almost certainly result in the destruction of the pyogenic organisms which has produced them. The little elevations will dry up and their career will be ended.

In summarizing, I repeat that the so called condition of furunculosis is a misnomer; that it is not a constitutional disease to be treated by internal remedies, but that it is simply the result of local points of infection originating from a parent source; that its treatment should consist in limiting the pus-producing agency within the bounds of its starting-point, and when this is not practicable, to destroy the pus-cocci by a strong solution of bichlorid of mercury before they are able to start new points of infection; that the so-called abortive treatment has little to commend it except in the very incipiency, and that a strong solution of corrosive sublimate is the agent *par excellence* to be depended upon for this purpose.

SPECIAL ARTICLE.

THE GARRISONING OF OUR TROPICAL POSSESSIONS.

No. 3.

THE SANITARY WELFARE OF PUERTO RICO.

By AZEL AMES, M.D.,

ACTING ASSISTANT-SURGEON, U. S. ARMY; SANITARY INSPECTOR, MILITARY DISTRICTS OF MAYAGUEZ AND PONCE, PUERTO RICO.

WHILE the series of articles of which this is the third is written with especial reference to the sanitary welfare of the American troops garrisoning our tropical islands, and primarily in their interest, it is impossible to intelligently discuss certain factors of the complex sanitary problem which this new dependency of the United States in the Antilles presents without consideration of broader and precedent conditions.

The island of Puerto Rico, lying between latitude 17° 54′ and 18° 30′ 40″ north, and between longitude 9° 34′ and °11 25′ east from Washington, is the most southerly of our recently acquired possessions (of any area) in the West-Indian Archipelago and constitutes in itself a Military Department or District of the United States. Standing, as it henceforth will, as the outpost of the American Republic in the North Atlantic every dictate of self interest and of patriotic pride should impel us to make it, in every feature, civil and military, fully the equal if not the superior of the British representations in the Bahamas or Jamaica, of the French at Guadaloupe or Martinique, or of the Danes at St. Thomas or St. Croix.

Although acquired by force of arms and hence technically conquered territory the *intente* and policy of the United States toward its people differs widely from that usually exercised under similar relations and materially affects the problems of its new rule. Of these problems none is so basic and important as that relating to the conduct of its sanitary affairs, whether considered with reference to the troops that form its garrisons or to the people who are its civil inhabitants.

It is doubtless fortunate for both that its governmental control is, and probably must be for many years, distinctly military, because it insures a degree of order and of stability in rule and in commercial affairs impossible to any other, and because it makes practicable methods, measures, and achievements, purely sanitary in character, not attainable under any but ample military authority. It is equally fortunate that the relation of the island to the United States is that simply of a Military Department or District, because as the "Orders" of the Military Governor, the General commanding the Department, are the *lex suprema*, we have in them a code of law alike simple and comprehensive, rarely difficult of interpretation and free from the entanglements of legislative enactment, and because, as a Department or district there is abundant Constitutional authority,[1] as well as precedent, for provision by Congress for all its requirements, without the involvements that attach to a territorial status.

Subject as the people of Puerto Rico have been for hundreds of years to the rapacious, tyrannical, and debasing rule of the Spaniard, the firm but kindly policy of the American Republic and that honest and efficient conduct of affairs which has everywhere characterized the officers of its Army can but produce appreciative and responsive efforts on the part of the people of the island as soon as their confidence is secured and the stimulus of example has had time to work. It will be helpful to an intelligent grasp of the subjects matter later under discussion if at the outset we briefly consider some of the conditions, natural, social, and governmental which more or less intimately and seriously affect the sanitary welfare of Puerto Rico, its garrison, and its people which existed at, or immediately upon, the formal surrender of the island to the Americans in October, 1898.

Situated in the semitropics, sea-girt, yet closely adjacent to numerous islands similarly conditioned and in close commercial contact with them; thrown up by some mighty submarine upheaval that made the coral reefs of the sea-floor its mountain crests; having an area of 3368 square miles of astonishingly broken and diversified surface, everywhere well watered and covered with luxuriant vegetation to its mountain-tops; having a heavy average rainfall and a mean temperature of 72° F.; its food-products chiefly those common to the semicultivation of the subtropics under Western European rule, Puerto Rico presents an assemblage of natural features and conditions, which have been proven by ample experience,

[1] Constitution of the United States, Art. IV., Sec. 3. Acts of Congress in aid of Alaska and Indian Schools.

decidedly inimical to the health of the Caucasian permanently resident and none too friendly to the native. The intense heat, alternated with frequent and heavy rainfalls; the supersaturation of the rich, alluvial soil; the extreme humidity from these and its sea environment; the rank growth and equally rapid decay of its vegetation, and the lack of sufficiently nutritive properties in its food-products are the most potent of the natural conditions provocative of disease in this beautiful island.

Upon these natural conditions and the native stock of Columbus' day have been engrafted from nearly every nation and clime a population formerly as heterogeneous as could be found in equal compass under the sun. Native, Spaniard, Malay, Corsican, Frank, Berber, Greek, Mongolian, and Hebrew, with now and then an infusion of British and American blood, have mingled here till some degree of homogeneity, with a few dominant strains, has resulted, some 300,000, according to the census of 1887 being blacks. The aborigine, long since blotted out by the vices and cruelty of his Spanish conquerors, gave place to the "flotsam and jetsam" of the Atlantic and Caribbean Sea, often the stranded buccaneers of Drake's, Hawkins', or Morgan's ships, the Malay or Greek corsairs, or the Frankish or Corsican pirates of the Sixteenth and Seventeenth Centuries. Under the iron hand of the Spanish rule and the no less powerful sway of the Roman Catholic Church came order, and in time, organization, some measures of tranquility and great prosperity. With the suppression of piracy the pursuits of commerce and agriculture became dominant and have been, for more than two centuries, the principal interests of the population.

It will doubtless be a surprise to many to learn that this population is not only greater than that of the State of Connecticut (being slightly larger numerically, upon a slightly smaller area), but is far more evenly distributed, making the whole island much more closely populated than Connecticut, as a large part of the population of that State is in its cities and large manufacturing towns, while Puerto Rico has few of the former and none of the latter. By the Spanish census of 1887 there were, approximately, 814,000 inhabitants, or, approximately, 220 persons to the square mile, and to state this is to name a most important factor of every sanitary problem. Of the personal characteristics of the mass of the population and their habits we have no need to speak except as they bear upon the question of sanitation. Indolence and laxity of morals everywhere surely beget poverty and disease. Both are "fast-colored" in Puerto Rico by the climate, the primitive condition of life, and the ease with which its actual necessities are met, while the rapacity of Spanish rule has doubtless done much to suppress ambition and promote pauperism and crime. Nowhere is the admirable Bavarian system of Count Rumford as preventive of pauperism among the people and idleness in the army more needed than here. Of course filth is everywhere a menace to health and filth conditions in and about the home are all too prevalent in Puerto Rico.

It is sad but true that there is very little of either religion, morals, or education in the island, though a laudable effort to establish schools has been made by some municipalities. The marriage relation is lightly held and an amazing proportion of the children are illegitimate. It goes almost without saying that with this large and mixed population so long under such rulers and in a tropical climate, every zymotic disease, every miasmatic influence, every contagious and infectious germ, finds congenial breeding-ground, and that malaria, smallpox, typhoid, venereal infection, etc., might be expected to sharply assert themselves, as they do. It is not intended, however, in this paper to more than outline those conditions which compel the consideration of efficient sanitary administration, leaving to later contributions the review of particular features, their relations, regulation, and control.

Upon the natural and social bases described and the wreck of Spanish misrule the United States military authority undertook upon its accession to establish a government for this insular Department. In accordance with the conciliatory policy of the administration at Washington certain heads of departments of the late Spanish Government at San Juan were retained, and an effort was made to galvanize into life and to engraft upon American Constitutional and Military Law and Practice the dead enactments of the defunct Spanish power. Both these steps, though undoubtedly taken with the best intentions and in the interest of good order and the least possible disturbance of existing conditions, appear in the light of experience, then lacking, to have been mistakes. That they have been productive of much misunderstanding, some distrust, and little good, cannot be doubted. Their bearing upon important sanitary measures will duly appear.

It is evident that the acts of municipal and other authorities of Puerto Rico, especially such as relate to taxation, land titles, the issue of municipal bonds, etc., *must* have sound and sufficient basis of law beneath them. Indeed, a fair and competent test of the adequacy of the law upon which a municipality and its acts stand is the salability of its debentures. If the organic act by which a town or city exists, and the law upon which each of the acts essential to the proper issue of its indebtedness certificates is based, can pass the scrutiny of the bankers of our money-centers, the legal as well as the financial status of that municipality, its officials and its issues may be safely considered sound.

The fact will readily suggest itself that the construction of sewers, which every principal city of Puerto Rico is practically without and sorely needs; of water-works and their improvements; of markets and abattoirs; of garbage and other crematories; of public baths, etc., all of which are seriously and zealously contemplated by the principal municipalities will require them to negotiate loans by sale of their bonds or other promises to pay. For these bonds to have any negotiable value in such money-centers as New York, Boston, or London, their legal status must, as already stated, be unimpeachable. The same will hold good of any boards, commissions, or other bodies upon whom may be devolved by the conjoint action of municipalities, or of the government with some of them, the construction of sanitary or other public works and of their debenture issues.

It is plain, therefore, that the creation of the larger and more important sanitary works, from which the most essential improvements in hygienic conditions must chiefly come, must depend (so far as they are municipal or conjoint constructions) upon the soundness of the legal basis upon which these cities and their negotiable securities rest. This basis hence becomes the foundation of the sanitary welfare of Puerto Rico, alike of its garrison and of its people.

Yet no satisfactory basis has existed since the advent of American rule, or seemingly can exist, until by adequate decrees and orders of the Military Governor (the supreme, the only valid law possible to this insular Military Department, except the Acts of Congress of the United States) due and proper existence is given to municipal alcaldes and councils, assessors, tax-collectors, registrars, constables, etc. The Spanish law is dead with the hand that gave it life and that alone could enforce it. It could not be revivified by any sweeping and inclusive order of a military commander. Its verbal incongruities alone forbid, while the grave incompatabilities which attended the effort to engraft its moribund decrees upon the virile American Constitutional and Military Law and Practice could not fail to prove abortive.

If it is desired to put in force certain provisions of the former Spanish law which commend themselves nothing can be easier than for the Military Governor, by the plenary power vested in him, to enact them by "General Orders" into that code of unassailable law which his successive and in nowise restricted "Orders" are building up as unimpeachable law for Puerto Rico. If, to carry forward in the only safe and practicable way apparent, the desire of the President and people of the United States, that the people of Puerto Rico shall be, as far as wise, given the management of their purely local affairs and be taught experimentally American methods of municipal control, it will be an easy matter for the Military Governor to create by "Orders" new charters for municipalities; to appoint proper enrolling officers for such districts of the island as he sees fit to establish; to fix the eligibility qualifications for enrollment as voters in these districts; to indicate the officers for whom they shall vote; to order and regulate the holding of elections for such officers, *e.g.*, alcaldes, councillors, constables, etc.; and to provide for their proper installation into, and the conduct of, their respective offices, etc. He would thus, at once, and by law and authority which cannot be questioned, while abating no particle of his power of veto or control, lay solidly the primary foundations of that local autonomy which the people of the United States and those of Puerto Rico alike desire the latter shall enjoy, and put the municipalities on a footing at once simple and satisfactory to the most critical investor.

Until this shall be done it is gravely to be feared that those cardinal improvements necessary to the sanitary well-being of some of the principal places cannot go forward from the inability of these cities to obtain, by pledges of their credit, although perfectly sound financially, the requisite funds. In such places only such improvements as the annual tax levy can meet, or as—from the benefit to accrue directly to the troops—may be met from the military chest, can be attempted.

It is so often impossible to secure sanitary conditions of primary importance to troops, as in matters of water- and food-supplies, sewerage, disposal of garbage, etc., except as general provision is made for the municipalities they garrison, that one is constantly reminded in military hygienic undertakings, as in civil, of the epigram of John Simon when Medical Officer of the Privy Council of Great Britain, that "We can only secure our own immunity from disease by caring for the health of our less-fortunate neighbors."

When troops are garrisoned in or adjacent to populous communities both are of necessity a constant menace to each other's health, as the experience of Spanish troops quartered in Puerto Rican and Cuban cities has so often attested. Under the advance in science, however, now available, and the control of a Nation of the high intelligence and resources of the United States to-day these danger conditions ought not only to be reduced to the minimum, but soldier and citizen ought to be intelligent and effective allies in promoting this reduction. Of the duty of the Nation itself it will not be gainsaid that to our representatives in arms in this outpost in the Antilles we owe every care, protection, and support that it is in our power to give, and to the people of Puerto Rico we owe the fullest recognition of the fact so well expressed by Kidd,[1] that "*We hold these new dependencies in trust for civilization.*"

A sound legal foundation, competent organization, executive men, and elementary education upon domestic hygiene among the children are the chief agencies demanded for the sanitary welfare of Puerto Rico to-day. The all-important relation which the garrison troops of the United States sustain to the general sanitary welfare and the considerations especially affecting the army itself will afford matter for my next paper.

MEDICAL PROGRESS.

The Ultimate Results of Curetting the Uterus for Puerperal Infection.—FERRE (*Centralbl. für Gyn.*, November 5, 1898) gives the results of thirty-four cases of curetting of the uterus for puerperal infection, and proves from these that curetting is a better treatment than irrigation, not only in its immediate effects, but also in the ultimate results. In instances where irrigation was the only method of treatment employed, recovery was often followed by subinvolution of the uterus, inflammation of the adnexa, and occasionally peri-uterine infiltration with pain and suppuration. Consequently curetting is to be advocated rather than simple intra-uterine douches.

Formation of Joints between Bones Normally Independent.—OLLIER (*Centralbl. f. Chir.*, October 22, 1898) showed long since that it is possible in men and in animals to create a joint between bones whose normal joint surfaces have been destroyed. Now he has gone a step further in his surgical attempts, and has succeeded in reestablish-

[1] Benjamin Kidd, "The Control of the Tropics."

ing motion at the shoulder, in a man who had lost the head of the humerus and the whole of the scapula in an accident twenty-two years previously. The arm hung helpless at the side. Ollier dissected the upper end of the humerus free from the scar tissue, resected a small portion, preserving the periosteum, and stitched both the bone and its periosteum to the clavicle, using two platinum stitches which were left in place. If a bony union had taken place there would still have been sufficient motion in the sternoclavicular joint to enable the patient to use his arm to some extent. There followed, however, only a fibrous union so that there was fairly good motion between the bones, especially in the anteroposterior direction. Particular attention was given at the operation to the separation and suture of the deltoid and other muscles about the joint, so that they should have a point of support on the clavicle and its fibrous attachments. The bandages were changed at the end of ten days, but the arm was kept immovable for four months. It appeared at first that there was bony union, but this soon became fibrous, and after years of practice, the joint had become a really good one, and the strength of the atrophied arm had so far recovered that the patient could carry as much weight with one hand as with the other, and without any apparatus he could put his hand on the opposite shoulder or the top of his head.

On the Nature of Immunity and the Cure of Infection.—EMMERICH and LOEW (*Munch. med. Wochenschr.*, November 8, 1898) have made important discoveries regarding immunity and the healing of infectious diseases. The full reports of their investigations have not yet been published, but the practical results are thus summed up by the investigators:

1. Many times a culture of bacteria will cease growing, although there is sufficient nutritive material, and the surroundings are favorable. This cessation of growth is due to the presence of enzyms which are formed by the bacteria themselves, but which ultimately dissolve the bacteria.

2. There are bacterial enzyms which are not only capable of destroying their own particular kind of bacteria, but other kinds as well, including pathogenic ones.

3. Since these bacteriolytic enzyms are capable of destroying bacteria in the living body, there is a possibility of stopping infectious processes by their use. For instance, it is possible to cure an otherwise surely fatal infection with anthrax inside of thirty hours by means of the enzym of bacillus pyocyaneus. Since a single cubic centimeter of this enzym solution will destroy in twelve to twenty-four hours millions of diphtheria, cholera, or typhoid bacilli in a test-glass it is possible that it may have the power of healing these diseases if rightly appiied. It has a similar action upon the bacillus of the plague.

4. Bacteriolytic enzyms are soon destroyed in a living body, and for this reason, although it is possible to cure an infectious disease, it is impossible to confer immunity for any long period of time. The enzym may, however, be combined in the laboratory with an animal albumin so that it will remain unchanged in the living body and confer immunity against particular kinds of infection. The investigators succeeded in this manner in making a rabbit immune to anthrax, and a guinea-pig immune to diphtheria. The so-called agglutination is the first stage of the destruction of the bacteria by the enzyms.

5. The difference in the reactions obtained with any given immunizing serum in the laboratory and in the living body is due to the presence or absence of oxygen. If this is excluded from the test-glass specific pathogenic germs in a test-glass are not only agglutinated, but killed and dissolved, a fact which has been shown by experiments upon the bacilli of cholera and typhoid.

The Oppler-Boas Bacillus in the Diagnosis of Gastric Carcinoma.—KNICKERBOCKER (*Phil. Med. Jour.*, November 19, 1898) discusses the importance of the Oppler-Boas bacillus in the diagnosis of carcinoma. It is an unusually long, non-motile, thread-like bacterium, found in the contents of carcinomatous stomachs. The germs lie end to end or at right angles to each other. So far as is known, it never appears in the presence of hydrochloric acid. Numerous observers have confirmed the presence of these bacilli in enormous numbers in cases of gastric carcinoma, and their absence, accompanied by the absence of lactic acid, in the presence of pyloric stenosis, is an argument against carcinoma. The best opinion seems to be that this bacillus, while not pathognomonic of gastric carcinoma, is very important in the diagnosis. The bacillus stains readily with the anilin dyes. Knickerbocker's experience coincides with that of the European observers, and from it he draws the following conclusions:

1. That, while not pathognomonic of carcinoma, the presence of the Oppler-Boas bacilli is of the utmost diagnostic value.

2. That their presence may be demonstrated in nearly all cases at some stage of the disease.

3. That in a large number of cases the bacilli may be found before the tumor has involved surrounding structures to such an extent as to make extirpation impracticable.

4. That in a limited number of cases the bacilli may be found before palpable evidences of tumor.

Sexuality in the Etiology of Neuroses.—FREUD (*Centralbl. f. inner. Med.*, November 5, 1898) laments the disinclination of patients and physicians to examine into the sexual history of the individual who is suffering from any neurosis. He makes the broad statement that in every case of neurosis there is a sexual etiology which can be brought out by the examination in the case of neurasthenia but which rests upon the sexual experiences of childhood in the case of psychoneuroses, and these have been often forgotten. Among neurasthenic patients there are two forms, distinct symptomatically and etiologically. One of these is marked by headache, lassitude, dyspepsia, spinal irritation, constipation, etc., and is due to excessive masturbation, or to frequently repeated nocturnal emissions. The other form is characterized by a sort of fear or anxiety, and is due to ungratified desire, as the result of interrupted coitus, etc. Some patients are seen in whom the occurrence of both causes have produced some of both classes of symptoms. The usual

therapeutic measures are directed to the strengthening of the individual, and to the preservation of his strength. They often fail of their purpose, because they do not take account of the sexual conditions of the patient. There are two new principles to be added: The overcoming of the habit of masturbation, which can only be accomplished in a sanatarium, under the constant supervision of the physician, and later when the aroused sexual appetite will no longer be suppressed, the introduction of a normal habit of coitus. Here the physician finds himself opposed to social problems. In the case of married people who are unwilling to have children, he must not refuse to listen to their difficulties, or he will only force them into their previous bad habits. Unfortunately, there is no means of preventing conception which fulfils all the requirements. Psychoneuroses, which are the result of unconscious sexual experiences in childhood, require a different treatment, and at the best are only to be mastered by much effort and patience.

THERAPEUTIC NOTES.

A Simple Method of Curing Aphonia.—ABRAMS (*Ther. Gaz.*, November 15, 1898) has used successfully the following simple method of curing aphonia. He marks with a pencil on either side of the neck the point where the superior laryngeal nerve sends its internal branch into the larynx. This is the nerve of sensation for that organ, as will be remembered. Then with chlorid of methyl, or a spray of rhigolen he freezes thoroughly the spots marked. The relief is in most instances instantaneous, and phonation which before was difficult or painful, can be performed with perfect freedom. Sometimes the relief thus afforded is of only short duration, and the freezing must be repeated one or several times. The method is relatively painless, and the results are phenomenally good. It is often of value, too, in neuroses of the larynx, like laryngismus stridulus, spastic aphonia, and in the laryngeal crisis of tabes dorsalis.

To explain the action of the method, Abrams suggests three hypotheses: (1) Freezing may act as a counter-irritant and the results achieved may be due to local or reflex action. (2) Freezing may act by producing physical changes in the underlying structures. (3) It may act as a shock.

He rejects the first of these hypotheses on the ground that the reduction of temperature is never great enough to produce the results in this manner. For the same reason the second hypothesis must be rejected. To produce nerve degeneration, the freezing must be of inordinate degree, or frequently repeated, as shown by experiments upon rabbits. The third supposition is therefore the probable one, *viz.*, that the cold acts as a shock and inhibits nerve action for a variable period. To inhibit the pathological action of a nerve, expresses the ideal attainment of therapeusis, and the advantage to a professional of regaining the use of his voice, even for a short time, needs no proof.

Septicemia Successfully Treated by Venesection and Infusion of Salt Solution.—YOUNG (*Maryland Med. Jour.*, November 19, 1898) reports a case of appendicitis in which operation was performed upon a fifteen-year-old boy. The appendix was found in an abscess cavity. It was removed and the abscess drained. The patient's condition was good during the day, but late in the evening the temperature reached 103° F. and the pulse 118. The condition grew worse the following day, and in spite of stimulants and enemata thirst and vomiting increased. Seven hundred c. c. of normal salt solution was injected beneath the right breast with no appreciable result. At 7 P.M., 36 hours after the operation, the temperature was 105.8°, pulse 156. The condition was one of general septicemia, and it was evident that extreme measures were necessary in order to save the patient. Under cocain a large aspirating-needle was inserted into the right bacilic vein. The blood-pressure was so low that only two and a half ounces of blood escaped. Thirteen hundred c. c. (nearly three pints) of normal salt solution was slowly injected, about one hour being occupied in the operation. At the end of that time the pulse had fallen to 130, and the temperature to 104° F. The improvement lasted only a few hours, and at seven o'clock the following morning 2500 c.c. (two and one-half quarts) of salt solution was injected. The temperature and pulse dropped almost to normal, the patient passed large quantities of urine, and made an uneventful recovery. Young considers that this case proves the necessity of injecting large amounts of saline solution in order to cure acute sepsis. If four and one-half quarts were required in a delicate boy of fifteen, probably six or seven quarts would not be too much for an adult. At any rate, little good is to be expected from the injection of two or three pints.

Advantages of Beta-Eucain in Producing Local Anesthesia.—BRAUN (*Arch. f. klin. Chirurg.*, vol. 57, p. 370) gives the result of a long series of trials of different drugs to produce local anesthesia. He found that the amounts of morphin which Schleich recommended for his local anesthesia were so slight that they had no paralyzing effect upon sensation, but that morphin even in such small doses has the unpleasant effect of causing edema. This is particularly noticeable in regions of loose tissue (operation for phimosis for example). He found that the effect of cocain was perceptible in as dilute a solution as 1-20,000. His trials showed him that eucain "A" was somewhat irritating and far below cocain in anesthetic power. With beta-eucain, however, he obtained good results, as good as those with cocain itself, as like cocain it had no irritating effect on the tissues, and was effectual in very dilute solutions. As it is less poisonous than cocain, and can be boiled repeatedly without loss of power, and will not degenerate when kept in dilute solution, it has important advantages over cocain for general use as a local anesthetic. The following solution is recommended:

℞	Beta-eucain	gr. i
	Sodii chloridi	gr. viii
	Aq. dest.	℥ ii.

The anesthesia produced by this solution will last from ten minutes to one hour, and there is absolutely no effect upon the healing of the wound.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the Medical News will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

PROFESSIONAL DIGNITY.

There appeared recently in the columns of one of the New York daily papers an article with the striking caption, "Race against Death for a Keg of Beer." It contained an account of "one of the unwritten laws" governing the ambulance corps of a well-known city hospital, and stated that as a forfeit for bringing a corpse into the hospital in the ambulance the surgeon in charge had to set up a keg of beer for his fellows. In order to escape the payment of the forfeit when ambulance patients are very low and each gasp may be the last, ambulance-surgeons are represented as "standing in" with the drivers of the wagons. The idea of this collusion between driver and doctor, though not explicitly stated, being evidently for the purpose, should the doctor be in danger of incurring the forfeit, of having the driver whip up his horses.

We have waited over a week to see some correction of this story, but none has appeared. A little inquiry brings out the fact that while the unwritten law mentioned has not all the force of a Draconian edict, there is, nevertheless, a foundation for the newspaper story. Without any but the kindliest feelings in the matter, we would suggest that the procedure is scarcely in keeping with the dignity that is expected of members of the medical profession even though these promising scions are only just entering upon their career. We appreciate, of course, that the establishment of the custom is due to an overflow of youthful spirits at the discomforture of a younger professional brother, but there is a passage somewhere about putting off the things of childhood when one is no longer a child, that we commend to hospital residents' meditation.

Besides the lack of dignity we see the possibility of two sources of danger to human life in the custom as outlined. Accidents to ambulances on our streets are frequent and serious enough without the possibility of their being added to by reckless driving because a foolish forfeit is to be avoided. For the young and inexperienced ambulance-surgeon, and at times, too, for the older hand, the thought of the ridicule that will follow the bringing in of a corpse may sometimes seriously hamper the judgment in the matter of the doubtful cases in which a rapidly fatal issue seems not unlikely. At such moments the medical man needs all his diagnostic and prognostic skill, and a judgment absolutely unhampered by any thought but what is best for the patient. This may be the delay of a few minutes until some reaction has set in before the ride to the hospital is attempted, or immediate rapid transfer to the hospital for the sake of the better conveniences there. May we say then, not in any carping or acrimonious spirit (we were young once ourselves) that the hospital-ambulance system will be better without the unwritten law in question.

ANATOMICAL NOMENCLATURE OF THE NERVOUS SYSTEM.

We publish this week an abstract of Professor Wilder's opening address before the recent meeting of the Association of American Anatomists. Our abstract represents fairly enough, as far as our space would admit, Professor Wilder's ideas, but we know that it does not do justice to his vigorous, finished style, and his persuasive method of presenting the subject. Some of the good points our reporter has caught, and we refer our readers to them.

The subject of reform in the anatomical nomenclature of the nervous system is a most interesting one. The crying need of reform is manifest. A

prominent psychoneurologist quoted by Professor Wilder thinks that one-half the time at present required for the study of the anatomy of the nervous system would be saved to the student if the reforms suggested could be carried into effect. Now is pre-eminently the time to introduce them, since of late years the great advance in our knowledge of neural-pathology and anatomy has made modifications doubly necessary. What has been discovered up to the present time, however, is but a mite compared to what lies within our reach in the near future in the comparatively unexplored fields of anatomical psychology and neurology.

It is unfortunate that the work so well begun by the committee of the Anatomical Association has been hindered by the overcautious, the too conservative, the too Germanic, and the let-well-enough-alone people, who fear the results of reform, and think Americans not in a position to think for themselves in the matter or to select for themselves the terms in English best suited for teaching purposes. In Oliver Wendel Holmes' words, it is difficult to teach an ancient canine new devices or an old professor new tricks. Perhaps, as Harvey said, "It is not to be expected that any one over forty should accept a new idea," and we must not look for reform in our generation. The need is so great, however, and becoming so much greater as the number of students increases that we heartily welcome renewed agitation of the subject. It is only by long-continued agitation that ideas as well as material particles that have no natural affinity can be gotten into contact so that when the moment of definite interaction comes they shall be in a position to accomplish the reactions expected of them. Let us hope that unlike inert natural elements, some extraneous force will not be required to start the process that will finally lead to union in the matter, but that the intellectum agens of the professorial body will prove to be the only factor needed to overcome the present inertia of a too halting conservatism.

THE PHONOGRAPH AND THE DIDACTIC LECTURE.

DR. HOLMES' suggestion made recently at the meeting of the Association of American Anatomists merits perhaps some consideration from professors of other branches of medicine than anatomy. The genial doctor suggests a phonograph loaded with what is best as to matter, and suave and taking as to manner, instead of the trite and commonplace didactic lecture, whose main purpose would seem only too often to be, to provide an hour of soothing rest for the overworked medical student. The wonderful influence claimed for the vox humana would not be entirely lost by the substitution, and the professor's precious time might be devoted to the more profitable labor (for science at least) of research and investigation.

One distinct advantage that we foresee would surely accrue from the use of the phonograph is that the next generation of medical men would probably be trained to something like uniformity in the pronunciation of medical terms. It is true the phonograph might require careful watching in this respect or, like a friend's typewriter (the machine) which he discarded because it spelled badly, this new mechanical labor-saving device might acquire bad habits. It would at least be consistent in its errors we feel sure and not accent the penult of a word at the beginning of a lecture and hammer out the accent on the antepenultimate at the end of it. But this is only a minor advantage compared to the fact that we could, with the advent of phonograph days, be sure of having an ideal set of didactic lectures as regards both matter and style. They could be made to equal the text-book, be kept thoroughly up to date, and small replicas of them might be furnished each student so that whenever he wished he could have a repetition of a specially exhaustive or peculiarly important lecture.

The discussion of Dr. Holmes' paper at the session of the Anatomical Association shows that at least professors of anatomy consider that the didactic lecture in the medical school has practically outlived its usefulness. It has still place in the curriculum, but instead of being of first importance the advance in scientific medicine and above all in the science of pedagogics have relegated it to a very secondary position. As a supposed conveyer of information, as a useful means of teaching anatomy, as the important feature of an anatomical course, the didactic lecture no longer has a place. There is a function for the lecture but not as a lecture. As Professor Gerrish said it is still of the greatest usefulness in blocking out work for demonstration. As an independent

entity it is bad, yes worse than bad, since it represents failure to advance in methods of teaching. Advance is patent all around us and medical schools ought to be among the first not the last to avail themselves of what is good in modern pedagogics.

We quit the subject for the moment regretfully, so much remains to be said, but we shall have something to say in this regard again next week in touching upon the discussion of "Advances in Methods of Teaching Science," which constituted the program at the recent joint meeting of the affiliated societies that make up the Association of American Naturalists.

TIGHT-LACING AND PERIODIC HEMATURIA.

PROFESSOR ROVSING of Copenhagen, very well known in Europe as a genito-urinary specialist and a conservative surgeon of acute observation, reports in the *British Medical Journal*, November 19, 1898, a case of hematuria occurring at intervals and finally so serious in character as to necessitate operation. It was found that the bleeding was due to the traumatic effect of extremely tight corsets "the superior pole of the kidney having been pressed between the liver and the ribs." Professor Rovsing concludes his report with the remark, "As I have never seen this alteration of the kidney mentioned among the sequelæ of tight-lacing I will call your attention to this fact as a hitherto neglected and perhaps frequent cause of r nal hemorrhage of apparently mysterious origin.".

The case is of additional interest because it occurred in a young woman of typically nervous diathesis, slightly built, frequently changing color, and varying humor, in whose case the temptation to diagnose some form of nervous hematuria would be especially strong. In the intervals between the hemorrhages the urine was perfectly normal. We are tempted to wonder how many of the cases of so-called idiopathic hematuria, hematuria without a cause, renal epistaxis, etc., or of such indefinite origin as "renal hemophilia," or "neurotic hematuria," or "hematuria neuralgia," or "malarial hematuria," with no other manifestations of malaria present, or finally that delightfully satisfying, because charmingly full-mouthed etiologic discovery, "renal angioneurosis" are due to this simple yet hitherto unnoted cause! In this connection attention is called to a pointed question in physics, presented in another column.

THE STUDY OF CONTAGIOUS DISEASES.

WE have waited patiently and spared comment in the hope of a reconsideration of the action of the Philadelphia Board of Health in refusing the request of the United Medical Schools of Philadelphia that opportunities be granted their students to see cases of contagious disease. It now seems, however, that their refusal to permit the wards of the Municipal Hospital (the city hospital for contagious diseases) to be used for the purpose of demonstrating types of contagious diseases to students is, for the time being at least, final. The reason given is the fear of the spread of the contagious disease. This is, we think, under the circumstances, a specious argument. It is the medical profession that has organized the present system of sanitation by which contagious diseases are rendered so innocuous in crowded centers of population and it is safe to infer that they may be trusted to take care that the study of them shall not prove a source of contagion.

This is a matter in which non-medical opinion should not have too great weight, and non-medical men the deciding voice. Philadelphia has, however, to her cost in medical matters at least, allowed non-medical opinion and lay officials to dictate the policy of her charitable institutions as far as regards the use of their patients for teaching purposes. There was a time when Philadelphia was the great medical center of this country. If in recent years her distinction in this matter has been gradually slipping away from her it has not been so much because her great medical schools have degenerated from their pristine vigor or because the profession in Philadelphia does not contain the giants there were in those days, as that the ultra conservatism of certain city officials have hampered medical teaching by refusing to grant it the opportunities so readily accorded elsewhere.

This last decision is of a piece with the rest of the narrow-minded policy the city officials have thought it best to follow. It caps the climax of that policy and stamps it as extremely short sighted.

Other cities have realized the necessity to the student of personal observations in cases of contagious

diseases. The facilities granted for study have, we believe, in no case had any serious result.

How much the medical men of Pennsylvania need this personal observation of contagious diseases is brought out clearly by the fact that there was, and if we mistake not, still is, an epidemic of smallpox in certain towns in the interior of the State, which was allowed to gain the hold that it has because it was at first unrecognized by the local physicians. They cannot be blamed, seeing that their only acquaintance with the disease was through the unsatisfactory medium of a text-book.

ENGLAND'S SCHOOL OF TROPIC DISEASES.

WE regret to say that the more the details of the plan of the English Government's new School for the Study of Tropical Diseases unfold themselves the greater the opposition to it becomes. This has now culminated in a memorial addressed to the *Times* by a committee of leading physicians, consisting of such men as Sir Wm. Roberts, Sir Dyce Duckworth, Sir Wm. Gowers, Burney Yeo, and others, protesting against the entire plan in its present form. They base their protest upon the following substantial grounds: First, that the proposed outlay for new buildings involved is $80,000, of which the Government promises *only $17,500*, the cost of maintenance, $15,000 a year, toward which the Colonial Office offers only *$5000 in candidates fees*, leaving $62,500, and $10,000 per annum to be supplied by the benevolent public upon whom *all the great hospitals* already rely for the bulk of their financial support. Second, that the proposed site at the Seamen's Hospital, Albert Docks, is extremely inaccessible, and the neighborhood utterly unsuited for the even temporary residence of students. Thirdly, neither the College of Physicians, nor any of the great medical schools, or recognized leaders in the profession have been consulted in any way. Even the staff of the hospital utilized received their first notification of the scheme through the newspapers by seeing there their own names as proposed teachers in the school.

The profession and the medical schools are anxious to concentrate their cases of tropical diseases at some central hospital and arrange for instruction in them without any of this excessive and needless expense, but they naturally object to being ignored in this high-handed manner. Besides, as Mr. Jonathan Hutchinson forcibly points out in the same issue of the *Times*, the profession has just organized a Polyclinic in a most central situation for the benefit of just such colonial physicians, medical missionaries, and other graduate students as the Government school expects to enroll, and the two institutions would be in direct and injurious competition with each other. As the Polyclinic is composed of representatives of every large hospital in London, and can draw its cases from the wards of all of them, it would certainly seem a pity that it and the School of Tropical Diseases could not be combined in some way instead of directly antagonizing one another.

The spectacle of the richest government and greatest colonizing power in the world calmly proposing to pay only *one-fifth* of the expenses of a school to devise means of making the tropics inhabitable by white men is an exhibition which ought to make even officialdom ashamed of its stinginess and stupidity. Considered even as a death-bed repentance for long years of ostrich-like and persistent ignoring of the inestimable services rendered the State by the medical profession it is absurdly inadequate.

ECHOES AND NEWS.

Dr. Little as Professor at Dublin.—Dr. James Little has been nominated as Regius Professor of the Institutes of Medicine at the University of Dublin, Ireland, to succeed Sir John Banks.

The Economy of a Vegetable Diet.—At the vegetarian restaurants now in operation in London a regular dinner can be had for twelve cents, and for thirty cents three meals a day are furnished. No element of flesh enters into the food, but it is said to be well-cooked, palatable, and well-served.

Examination of Applicants for the Marine Hospital Service.—A board of officers will be convened at the United States Marine Hospital, Chicago, Ill., February 14, 1899, for the purpose of examining candidates for admission to the grade of assistant-surgeon in the United States Marine Hospital Service.

Sick Report from Honolulu.—Mail received at San Francisco on the 3d inst. states that two soldiers recently died from typhoid fever. Seven or eight soldiers of the First New York are still at Hilo, too sick to be removed to Honolulu. About 100 convalescents, mostly of the First New York are in a convalescent camp.

Donation to the Lawrence Scientific School, Harvard.—Mr. Charles Wheeler of Philadelphia has given $5000 to Harvard, in memory of his son, Stuart Wadsworth Wheeler, Class of '98, who served during the campaign in Puerto Rico and died in Boston recently, his health having been undermined during the hardships of the campaign in the tropics. The money is to be invested, it is said, and the interest used as a loan fund in the Lawrence Scientific School.

Dr. Von Esmarck's Suggestion.—Dr. Von Esmarck who, through his wife, is closely connected with the imperial house, has written a paper in which he states his opinion that the Czar's conference should aim, at least, to mitigate the horrors of war. The doctor protests against the use of the dum-dum bullet in civilized warfare, and urges that all small-caliber bullets should be cased entirely, or at least at the point in hard metal. Every soldier should, in his opinion, be instructed in Red-Cross work.

The Micro-organism of Faulty Rum.—In the *Lancet* of December 10, 1898, it is stated that this micro-organism has been found; we are informed that it has hitherto escaped observation because it was supposed that no organism whatever could live in liquid of such alcoholic strength as rum. This discovery may prove a valuable addition to the temperance-advocate's armamentarium. No doubt this micro-organism, when magnified upon the stereopticon screen, will be found a hideous monster.

A French Medical Review Suspends.—It is announced that the *Revue des Sciences Medicales*, a quarterly review of reviews in medical literature very well known in other countries as well as in France is about to suspend publication. The *Revue* was established nearly thirty years ago. For the last few years it has been under the editorial direction of Professor George Hayem, the well-known Professor at the University of Paris and the author of a number of books and articles on clinical medicine.

Liquid Air.—The profitable uses that can be made of liquid air, especially in hospitals, are almost unlimited. A quart of it placed in a ventilator will furnish pure air for a day. Fever patients can be kept in rooms cooled to zero, even in the tropics, which would make the nursing of yellow fever perfectly safe, and at the same time, facilitate the recovery of the patient. It might be used with great advantage as a cauterizing agent in cancer, as its action is perfectly under control, and can be instantly stopped.

Can Be Read Backward or Forward.—"The fundamental propositions of Christian Science are summarized in the four following *self-evident* propositions. Even if read backward, these propositions will be found to agree in statement and proof. 1. God is All. 2. God is Good; Good is Mind. 3. God, Spirit being all, nothing is matter. 4. Life, God, omnipotent Good, deny death, evil, sin, disease. Disease, sin, evil, death, deny Good, omnipotent God, Life." From "Science and Health," the Christian Scientists' *vade mecum*.

A Sanatorium for Americans at Nagasaki.—The authorities at Washington are said to have under consideration a plan for establishing at Nagasaki, Japan, a sanatorium for American civilians and soldiers who have been debilitated by the climate in the Philippines. Nagasaki is not especially well equipped for a health-resort, and its climate and surroundings are not appreciably different from those of Manila or Iloilo. There are mountains in the Philippines on the sides of which the debilitated could breathe comparatively cool and pure air and could live among hygienic surroundings.

Pharmaceutical Possibilities.—The "class yell" of the Juniors in Pharmacy at Purdue University runneth thus:

> Physostigma venenosum! Pilocarpus nodulosum!
> Staphisagria, bergamot!
> Pharmacy, pharmacy,
> Naughty naught!

There is a disregard for Latinity in it that finical and supercilious criticism might designate as typically pharmacal, but it illustrates the vocally *noisome* possibilities that exist in the orotund Latin drug names in a way that has never been brought out before. Not everything under the sun in pharmacy is old.

Noise as an Etiological Factor.—Dr. R. W. Hastings has written a paper on this subject which appears in the *Journal of the American Medical Association* of December 24, 1898. He enumerates a number of noises, to which he would certainly have added in italics, had he experienced it, the noise produced by the closing of doors on the Metropolitan Company's street-cars of this city. The conductor seizes the handles, grins like a torturing demon, and then these doors collide with a noise like the simultaneous and concentrated report of a company's musketry fire; it is absolutely unnecessary and certainly avoidable.

Acetanilid Sold for Phenacetin.—Dr. Henry Schmeitzer, an expert chemist, has analyzed a quantity of packages of so-called phenacetin; these samples were found to be mixtures of acetanilid with flour, starch, sugar, bicarbonate of soda, chalk and citric acid. Acetanilid costs fifty cents a pound, while phenacetin costs eighty-five cents an ounce. According to the New York Board of Health, other drugs largely adulterated are citrate of magnesia, bisulphate of quinin, cream of tartar and acid phosphates. The inference is that in using these drugs one should make sure that he has procured the genuine article.

Fire-proof Buildings for the Insane.—The New York Commission in Lunacy has upon its hands the construction and equipment of a new group of cottages, to be built at Central Islip, Long Island, for the Manhattan State Hospital for the Insane. The buildings must be heated, ventilated, and supplied with water and a plant for electric lighting, and the cost must be kept within the amount of the appropriation fixed by law, namely, $500 per patient. This *per-capita* outlay is too small to admit of the Commission entering into contracts that will provide structures that are proof against fire, and it is stated that New York is the only State in the Union that is now building its structures of wood. In case of a fire there is not a more helpless class of people imagina-

ble than the insane. They either sink down to the floor in despair, refusing to make any effect to save themselves, rush wildly into the flames, or leap from upper-story windows to their death. In view of the horrible loss of life in the burning of the State Hospital for a similar class of patients in Illinois, in which scores of patients lost their lives, it would be an act of criminal folly to erect, out on the open plains of Long Island, far from the protection of an adequate fire-department, a group of buildings, the whole interior of which is to be constructed of inflammable wood, through which a gale of wind would sweep a fire with terrifying rapidity.

A Question in Physics.—The accompanying illustrations clipped from a fashion-plate were pinned to a note and forwarded, with the following comment, to Dr. Howard A. Kelly of Baltimore, by one of his younger patients, with whom he had been doing some missionary work along the lines of health and hygiene: "Do you

FIG. 1.

Style No. 400. Ladies' Bicycle waist.

FIG. 2.

Style No. 245. For misses 10 to 16 years of age.

suppose the poor fools who wear No. 400 think their waists get naturally smaller after sixteen? It would be unbusiness-like for doctors to complain. It is so hideous that artists might. Where do you suppose her 'superfluous' (?) insides are? In her shoes?" It is a hopeful sign of the times that our women patients begin to think and to ask such questions.

The New York Academy of Medicine.—At a stated meeting of the New York Academy of Medicine, held Thursday evening, January 5, 1899, the newly elected President, Dr. W. H. Thomson, took the Chair. In his retiring address the late President, Dr. E. G. Janeway, reviewed the work of the Academy during his term of office and dwelt at length upon the report of the Library Committee. He alluded to the fact that the library of the Academy, by reason of the generosity of the trustees of the New York Hospital in their gift of the library of that institution, is now next to the largest medical library in the United States, being surpassed only by that at Washington, and strongly urged the members to make every effort toward the completion of the Library Endowment Fund. He expressed the hope that the debt of the Academy might speedily be wiped out by individual subscription and stated his willingness to contribute his share toward that much to be desired end. He touched upon the laboratory connected with the Academy, which he considers of great importance in increasing its influence in the profession and which he thinks can and should be made self-supporting. He strongly urged that efforts in this direction be made when the Library Fund is completed. He also referred to the report of the Committee on Expert Testimony in Court which was appointed to frame a bill leading to reform which the Academy could support. He said he desired to thank the Chairman, Dr. Starr, for his earnest efforts in this direction and attributed the little progress which had been made by the Committee to the fact that there are many obstacles to be encountered, the chief of which is the difficulty in gaining the cooperation of the legal profession and in inducing the judiciary to accept a reasonable bill. He expressed the fear that reform will not come in this century. He referred with regret to the resignation from the Board of Trustees of the Academy of Dr. A. Jacobi whose efforts had done so much to make the organization what it is, and, in closing, expressed the hope that under the leadership of his honored successor the Academy would prosper as it never has before. In his inaugural address Dr. Thomson, after thanking the Fellows for the honor they had conferred upon him, spoke of the purpose for which the Academy was founded, viz., to advance the progress of medicine, and expressed regret that the growth of specialism had necessitated the breaking up of the body into sections. He referred to the time when weekly general meetings were held, at which topics of universal interest were discussed and which were largely attended by the general practitioner, and suggested that the progress of medicine could best be advanced by the discussion at consecutive general meetings of such subjects as syphilis, for example, from the various standpoints of the general practitioner, the dermatologist, and the neurologist. The latter part of the address was devoted to a consideration of immunization, vaccination, serum-therapy, and the etiology of edema. Before the close of the meeting an oil portrait of Dr. Joseph D. Bryant, former president, was presented to the Academy, the presentation address being made by Dr. A. Jacobi.

SPECIAL ARTICLE.

SCIENTIFIC AND EDUCATIONAL REFORMS.

MEDICAL NOTES FROM MEETINGS OF SECTIONS OF THE ASSOCIATION OF AMERICAN NATURALISTS HELD AT VARIOUS EDUCATIONAL INSTITUTIONS IN NEW YORK CITY DURING CHRISTMAS WEEK, 1898.

PROFESSOR BURT WILDER of Cornell University, President of the Association, opened the general session with an address on some misapprehensions as to the simplified nomenclature of neural terms. He spoke at considerable length, more especially of two sources, of misapprehension as to the neural terms that had been suggested by him and recommended for adoption by a

majority of a committee of the American Association of Anatomists appointed for that purpose. There is a false impression abroad that it is his personal influence that swayed the majority of the committee, in spite of the well-known fact that the other members who signed the majority report are independent thinkers, interested teachers, and capable investigators. It is also thought that most of the terms recommended for adoption are new and unusual in English. Nothing could well be more false. Barclay in 1803 had suggested some of them, especially the much-discussed terms of intrinsic toponymy. Owen had prophesied in the '40s that substantive anatomical terms because of their helpfulness to teacher and pupil would surely come in. Pye Smith in 1877 spoke strongly in favor of simplicity and took almost the very ground which the committee of the Anatomical Association now recommends for adoption.

Oliver Wendell Holmes in a personal letter to Professor Wilder some years ago said he did not hope to see the reforms in his day. "It was hard to teach ancient canines new devices or old professors new tricks." He hoped, however, that the agitation would be continued until even "that capricious dame Science would consent to try on the new-fashioned garment."

Professor Wilder acknowledged that the continuance of the agitation is not pleasant, but the number of students in this department of science will in the future be so great that the present discussions and the unpleasantness they involve make it well worth the effort to simplify the subject for them. Spitzka has stated it as his opinion that half the labor of the anatomical student of nervous tissues will be saved by the introduction of the new terms.

As to the opposition to the contemplated reform, a good deal of it is due to "certain habits of uncritical imitation and unreasoning opposition to what appears new, because unfamiliar, which man shares with the other mammals." Wordsworth had summed it up in the well-known lines,

> "I do not like you Doctor Fell,
> The reason why I cannot tell
> I do not like you Doctor Fell."

A certain amount of opposition comes from the fact that the German Anatomical Society, utterly disregarding what has been done in England and America in the line of simplification, has adopted another nomenclature. The Germans claim to desire unity in the matter. Some married men say that man and woman are one, but the man is *the* one. It would seem that the German desire for oneness premised the proviso that the German should be *the* one. In any case it is to be remembered, with the present racial impulses at work, that what is English will eventually prevail. A certain condescension in foreigners had been noted long ago and we must simply go about our business for ourselves, assured that in this as in everything else all will come out right in the end.

The passage on the quasi-military despotism of General Usage and the similitude, comparing reform to the incoming tide, are so forceful that we reproduce them verbatim. The latter Professor Wilder quoted from an unknown source, as did Kipling the couplets that appeared at the head of certain of his short stories. We have been tempted to think that both writers could say more of the origin of their quotations if they wished:

"It has been urged that members of this association should defer to what is called General Usage. Of all so-called leaders the most incapable, blundering, and dangerous is *General* Usage. He stands for thoughtless imitation, the residuum of the ape in humanity, for senseless and indecorous fashions, the caprices of the demi-monde, for superstition and hysteria, the attributes of the mob, for slang, the language of the street hoodlum, and of his deliberate imitator the college sport, and finally in science for the larger part of the nomenclature of the brain.

"As scholarly anatomists it is at once our prerogative and our duty to scrutinize and reflect and to deal with the language of our science in the same spirit and with the same discrimination that we practise in regard to the facts and generalizations thereof.

"When the first little wave of the rising tide comes creeping up the shore the sun derides her, and the dry sand drinks her, and her frightened sisters pull her backward, and yet again she escapes, and still her expostulating sisters cling to her skirts, and the rabble of waves behind cry out against her boldness, and all the depths of the ocean seem to rise to drag her down, and now the second rank of waves who would have died of shame at being the first have unwillingly passed the earlier mark of the little wave that led them, and now you may float on in your ship for lo, the tide is full.

"So it is with all systems of reform. Though the pioneers be derided the great needs of humanity behind push on to triumphant acquisition of the new order of things."

DR. HOLMES, Demonstrator of Anatomy at the University of Pennsylvania, then read a paper on the defects in our present methods of teaching anatomy. He considers that the first defect to be remedied is the matter of preparation for the anatomical course before beginning the study of medicine; this preparation to consist not alone in a better general education but in a certain amount of special scientific training which every studen who intends taking up the study of medicine should have the opportunity to acquire during his last year or two as an undergraduate. The present method of teaching anatomy is especially defective because it gives too important a place in the curriculum to the didactic lecture. If there is any branch of medical work in which the merely didactic lecture is out of place it is in the study of anatomy. There are some who still insist on the influence upon the student's mind of the personality of the lecturer, and the magic of his voice to impress great principles and give a living grasp of the important points among the infinite details of the vast subject. If the human voice is so wonderful then Dr. Holmes suggests that a committee of the Anatomical Association, composed of our best teachers of anatomy be appointed to draft a set of lectures which the man possessed of the most finished style shall put into vigorous pellucid English, and the most eloquent, whose voice is warranted to keep the most dys-

peptic of students awake even after dinner, shall talk into a series of phonographs. Replicas of these phonograms shall be furnished to all the medical colleges and lo, we shall have an ideal didactic course in anatomy.

The practical study of applied anatomy is too important a matter to allow its advance to be hindered any longer by old time methods. Practically, all surgical mistakes, at least in the early years of practice, depend on the neglect to bring the study of applied anatomy up to the pedagogic standard that already exists for other sciences.

A. C. LANGMUIR read at a session of the American Chemical Society a paper of special interest on the determination of arsenic in glycerin. Mr. Langmuir considers that traces at least of arsenic are to be found in all glycerin. He attributes its constant presence not always to the employment of arsenic in its manufacture with consequent contamination of the product, but thinks that arsenic is to be found naturally in the fat from which glycerin is obtained. Animals consume a certain amount of arsenic, and this is deposited in the fat of their tissues to appear later on in products obtained therefrom. Most of the present methods of obtaining glycerin demand the use of arsenic but Mr. Langmuir has succeeded in demonstrating the presence of the poison even when none had been used by the manufacturers of the glycerin.

The paper led to a good deal of discussion, much of which showed a strong tendency to oppose the view that arsenic was deposited in animal fat, and that the contamination of the glycerin occurred in that way. Some years ago when for a time glycerin was lauded as a specific for most constitutional troubles that involved loss of weight, the results obtained from its use in large quantities were so contradictory in different parts of the medical world that the present discussion will be welcome should it help to clear up certain doubts as to the uniformity of its composition as made by different methods. As glycerin still occupies a not unimportant place in the Pharmacopœia the subject is of no little present interest.

PROFESSOR GERRISH of Portland, Me., spoke on the order of topics for the course in anatomy; the use of charts and blackboards and the relative value of didatic methods. The blackboard and sketching has been in Professor Gerrish's experience of much more value than the most elaborate charts. There is a living interest in seeing the parts sketched even imperfectly, that cannot be aroused by any mere chart, however well executed.

It is to be remembered, moreover, that a system of recitation is an important function of all proper teaching of anatomy. It impresses important points and leads to the correction of erroneous impressions. Examinations in anatomy should not consist merely of question and answer, the text-book supplying the information and a good memory being the only requisite to secure good marks, but the student should be placed before a dissected subject and asked to demonstrate instead of explaining.

PROFESSOR HUNTINGTON of the College of Physicians and Surgeons of New York City spoke on practical anatomy and how to teach it and on the order of topics. He considers that the teaching of practical anatomy requires the coordination of oral teaching with practical work. This demands the division of the class into sections so that each student shall get personal instruction. A competent staff of demonstrators must be provided for the dissecting-room, so that the anatomical material and the magnificent opportunities it affords for training in practical anatomy shall not be allowed to go to waste as has been the case too often in the past. As to the order of topics he considers that the viscera should be taught first and that there should be a coordination of the physiology and anatomy courses so as to secure the most effective results.

At the afternoon session Professor Huntington spoke on the morphology and phylogeny of the vertebrate ileocolic junction. He traced the cecum or its equivalent through all its evolutional phases, illustrating his remarks by stereoscopic slides of specimens from the various mammals. The hour's talk was an excellent example of the value of comparative anatomy in teaching human anatomy and furnished a sample of the illustrated didactic lecture, that medical men generally would not willingly see barred from the curriculum.

DR. MARTIN read a paper on the examination of the cecum and appendix in one hundred subjects, which will evidently lead to the modification of some at present accepted views as to the blood-supply and peritoneal attachments of the appendix.

PROFESSOR HUNTINGTON in the discussion of the paper called special attention to the fact that while Zuckerkandl had found obliteration of the lumen of the appendix in 50–60 per cent. of the cases examined by him, Martin had found it in a very small number of cases and those found had occurred only in subjects more than sixty years of age.

PROFESSOR DWIGHT of Harvard asked if any vascular connection had been found between the ovary and appendix in female subjects. Dr. Martin replied there had not. Professor Dwight said that personally he had always considered any vascular connection reported to have been found between these structures accidental, the result of pathological adhesions. The organs were developed from entirely different embryological elements and any vascular connection must be pathological and acquired.

DR. HAYNES of New York City gave an explanation of a new method of cutting gross sections of the cadaver with demonstrations of the technic. He is able after an injection of a four-per-cent. solution of formalin once and a two-per-cent. solution twice during the course of a week, to make complete sections in any direction of children's cadavers, so as to make specimens for the demonstration of visceral relations that are almost, if not quite, equal to frozen sections for teaching purposes, yet are made practically with but a tithe of the labor and care required by the old method.

A New York Hospital Changes Its Name.—It is officially announced that the New York Cancer Hospital will hereafter be known as the General Memorial Hospital.

CORRESPONDENCE.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

GOVERNOR HASTINGS' ANNUAL MESSAGE — AN AGE LIMIT FOR TEACHERS—THE SAMARITAN HOSPITAL ENTERTAINMENT—ANNUAL ELECTION OF THE COLLEGE OF PHYSICIANS—SOME RECENT HOSPITAL BEQUESTS — PERSONAL NOTES—OBITUARY — HEALTH STATISTICS.

PHILADELPHIA, January 10, 1899.

GOVERNOR HASTINGS' message, which was sent to the Legislature last Tuesday, contains some excellent suggestions. He calls attention, among other things, to the wretched overcrowding of the State hospitals and advocates the county's care of its own indigent insane, a plan which has been in operation since May, 1897. He also urges the need of separate hospital care for epileptics and favors the adoption of a plan similar to that in existence in New York and some other States. The Governor states that there is one epileptic in every thousand persons in Pennsylvania.

An insane hospital, erected within the guard-walls of the State's penitentiaries, is recommended for the care of insane convicts of whom there are about 200 in the State. Attention is again drawn to the filthy condition of many streams of the State which are alike used for drinking purposes and for sewers. The message is an excellent exposition on sanitary matters relating to the State and though the Legislature will probably pay the usual scant attention to additional State necessities, water in time wears away rock, repeated drilling in time may pierce legislative skulls.

It is to be regretted that a system such as prevails in German universities, of retiring teachers after a certain age limit, does not obtain in this country. This is forcibly brought to mind by the fact that no less than two of our local medical schools are seriously handicapped by having upon their teaching force men, who, while brilliant and able in their day, are far from being able to satisfactorily fill the positions they still continue to occupy. An institution burdened in this way is helpless for the elections are made for life, and not realizing their decay, these veterans still remain monuments of a past glory and obstacles to further advancement. But one way, and that a clumsy one, remains to shelve a worn-out teacher, namely, by making his position emeritus. That this is frequently combatted vigorously is shown by the failure of a recent attempt to do this, the prospective recipient declining the position with tears of gratitude for the proposed honor! Fools step in where angels fear to tread and constantly dwindling clinics may be less delicate, but equally effective as hints from friends and fellow-teachers.

The Samaritan Hospital has been placed in an unenviable position by reason of a collector who was employed to manage an entertainment to be given by the hospital. At a meeting of the Board of Trustees, held on Saturday, it was determined to refund all money collected as the collector was taking fifty per cent. of all donations made, while the trustees' understanding was that fifty per cent. of the gross receipts of the entertainment should be received by him to defray the cost of renting the Academy of Music and other expenses incident to the occasion. About $1000 was donated upon which the superintendent allowed the collector fifty per cent. under the impression that the money came from an advance sale of tickets. The proposed entertainment has been abandoned.

January 2d the annual election of the officers of the College of Physicians took place, resulting as follows: President, Dr. John Ashhurst, Jr. (reelected); vice-president, Dr. William W. Keen (reelected); treasurer, Dr. Richard H. Harte; secretary, Dr. Thomas Neilson; honorary librarian, Dr. Frederick P. Henry; librarian, Charles Fischer. Two new councillors were elected, Drs. Henry R. Wharton and Morris J. Lewis, the others remaining unchanged with the exception of Drs. Packard and Dulles, whose terms had expired. The censors are Drs. Alfred Stillé, William F. Norris, Arthur V. Meigs, and Richard A. Cleeman. Library, hall, and other committees were appointed with but few changes in the present members.

The Training School for Feeble-minded Children at Elwyn has been left $2500 by the will of the late Francis M. Brooke. The income of the money is to be used for the entertainment of the children.

Judge Mayer Sulzberger and the co-executors of Simon Muhr's estate have just made a third distribution of the money left by him to charity. The total amount is $42,000 which, with the $126,000 already divided, makes a total of $168,000, with the likelihood that a fourth distribution will be made in the near future. Among the institutions which received this last instalment are: The Jewish Hospital Association of Philadelphia, $7000; the Pennsylvania Hospital, $1400; the Jefferson Medical College Hospital, $1400; the Hahnemann Homeopathic Hospital, $700: the Philadelphia Polyclinic Hospital, $700; the Philadelphia Lying-in Charity, $560: the Women's Hospital of Philadelphia, $560; the Children's Hospital of Philadelphia, $560. In addition to these sums every home for old people and children, every sanitarium association, day nursery, etc., received sums varying from $260 to $1500.

Another generous gift of last week was that of Peter A. Schemm, who, with his mother, gave $5000 for the maintenance of a free bed in the German Hospital in memory of the late Peter Schemm.

By the will of L. Taylor Dickson, who died recently, his entire estate amounting to about $100,000 is to revert to the Pennsylvania Hospital upon the death of the five beneficiaries to whom it is left in trust during their lives.

Dr. Florence Watson, Pathologist to the State Hospital for the Insane at Norristown, has resigned on account of ill health and Dr. Edith Barker of the Delaware Insane Hospital will, in all probability, be elected to fill the position thus made vacant.

Dr. B. Franklin Stahl has been appointed Lecturer on Dietetics at the University of Pennsylvania and Dr. Thomas S. Kirkbride, Jr., has been appointed Director of the Laboratories of the Philadelphia Polyclinic. The

laboratories are to be thoroughly reorganized and an effort will be made to bring this class of work at the Polyclinic into more prominence.

Drs. Emil Hertel, D. I. McCalley, Thomas D. Cook, and George Steinicken have been appointed vaccine physicians by the City Council of Wilmington. The Berks County Prison Inspectors have elected Dr. S. T. Schmell as physician to that institution.

William Potter, ex-Minister to Italy and President of the Board of Trustees of Jefferson Medical College, is said to be President McKinley's selection for the post of Ambassador to Russia.

Dr. Charles C. Lange, a graduate of the University of Pennsylvania, died suddenly at his home in Pittsburg, on January 3d, aged fifty-six. Dr. Louis A. Livingood, a graduate of Jefferson Medical College, died at Womelsdorf, January 6th, aged 68.

The total number of deaths occurring in Philadelphia during the week ending January 7th, as reported at the health office, was 713, of which number 185 occurred in children under five years of age. The total number of new cases of contagious diseases was 307, reported as follows: Diphtheria, 95 cases with 23 deaths; scarlet fever, 32 cases with 5 deaths; typhoid fever, 180 cases with 24 deaths.

MEDICAL MATTERS IN CHICAGO.

[From Our Special Correspondent.]

SYMPTOMS AND DIAGNOSIS OF MOVABLE KIDNEY—SURGICAL TREATMENT OF MOVABLE KIDNEY—EDITORSHIP OF THE "JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION"—SUPERINTENDENT OF ELGIN ASYLUM—ANNUAL REPORT OF COUNTY PHYSICIAN—IMPROVEMENTS IN COOK COUNTY HOSPITAL—HEALTH STATISTICS OF CHICAGO DURING THE PAST YEAR—NEBULIZATION IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

CHICAGO, January 9, 1899.

AT the December, 1898, meeting of the Chicago Gynecological Society, Dr. H. B. Stehman dwelt upon the symptoms and diagnosis of movable kidney. In considering the subject of differentiation, he said there are several anatomic and pathologic facts, which, if kept in mind, will help one materially: (1) The post-peritoneal position of the kidney as compared with the liver, spleen, gall-bladder, and various cysts and growths within the abdominal cavity, which can be easily demonstrated by combining percussion with inflation of the bowel. (2) The reniform shape of the kidney in comparison with the characteristic shape and feel of the spleen, liver, gall bladder, etc. (3) The immobility of the displaced kidney during inspiration and expiration, as compared with the descent and ascent of the spleen and liver and growths connected with them during respiration. (4) The pulsation of the renal artery, which, if felt at all, will always be recognized as part of the pedicle, for it must be remembered that the range of motion of the kidney is determined by the vessels, nerves, and ureter. (5) The ease with which the organ can frequently be moved from place to place and restored to its normal position in comparison with organs or growths whose positions are fixed. (6) Tenderness on pressure and the sickening sensation which is produced by compressing the organ between the two hands.

In ovarian cyst the development of the tumor and recognition of its origin may be determined by vaginal examination. In echinococcus cyst, that is, pedunculated, differentiation may be quite difficult, unless a hydatid fremitus can be felt; otherwise recourse can be had to aspiration. In fecal impaction, copious enemata with the liberal exhibition of cathartics will rarely fail to clear up the diagnosis; and if the coprostatic mass envelops the kidney, by dislodging the same the bean-like form of the organ will stand out in plain relief. It should constantly be borne in mind that excluding the symptom of pain, the movable kidney has little in common with ordinary inflammation, and thus in the presence of the characteristic symptoms of appendicitis or the edema, redness, tenderness upon pressure, with probable fluctuation of a perinephritic abscess, the physician should hardly fall into the error of confounding either of the two with displacement of the kidney.

At the same meeting, Dr. L. L. McArthur read a paper on the surgical treatment of movable kidney. He believes he has made a step in advance toward the ideal by a procedure with which all perforating sutures of the kidney parenchyma may be abandoned while supplying a fair substitute for the folds of peritoneum and transversalis fascia which normally hold the kidney in place. He has satisfactorily accomplished it in this manner: (1) A curved transverse incision below the last rib is made anteriorly through all the structures down to the peritoneum. (2) The peritoneum is then by blunt dissection loosened from lateral parietes sufficiently to permit boldly enlarging the posterior angle of the wound without fear of injury to important structures quite back to the quadratus. (3) The fatty capsule of the kidney is loosened by blunt dissection. (4) The anterior layer of the lumbar fascia is then loosened from the tissues on which it lies to such an extent as will admit the kidney in the pocket thus made. The lower flap of the wound now has a compartment for the lower half of the kidney. (5) Prior to inserting the kidney in the new compartment, two or three stitches are inserted into the cut edges of the transversalis aponeurosis, which serve to pucker the pocket containing the kidney. (6) The kidney having been dislocated first upward, its lower end is slid into the pocket. (7) Closure now of the stitches in the aponeurosis of the transversalis fixes the lower half of the kidney external to one of the layers of the abdominal parietes, supporting the same by so broad a surface that no injury to the kidney can result, and no displacement can occur. Dr. McArthur has found the pocket for the lower half of the kidney sufficient, and suggests its use in the movable cases, where a very complete arrest of its wanderings can be secured; two or three stitches can be made to hold the kidney until adhesions form. By this arrangement, too, the movements of the other abdominal organs cannot dislodge the kidney in question, it being external to one of the layers of the abdominal wall,

pressure from above tending to drive it deeper into the pocket thus formed.

A call was issued for a meeting of the Board of Trustees of the American Medical Association shortly after the death of Dr. John B. Hamilton, with a view to selecting an editor for the journal. Accordingly, the board held a conference January 3d. Numerous candidates for the editorship are springing up all over the country, Chicago having 5, Philadelphia 3, Cincinnati 1, New York 1, and St. Louis 1. It is said that the members of the board have been literally besieged with letters and telegrams extolling the virtues and abilities of certain candidates and pointing out the weaknesses of others. One or two out-of-town members of the board, fearing they would be pestered with visits from wire-pullers, stopped at a certain hotel in this city without registering. After discussing freely the qualifications of the various candidates, the board adjourned without selecting an editor. At its February meeting it will reconsider the matter. Dr. Truman W. Miller, a Chicago trustee, is at present acting as supervising editor of the journal at the request of the board.

No one has received as yet the appointment of Professor of the Principles of Surgery and of Clinical Surgery in Rush Medical College, a vacancy caused by the death of Dr, Hamilton. It is thought that either Dr. D. W. Graham or Dr. Arthur D. Bevan will secure the position. The latter is now Professor of Anatomy in Rush Medical College. Dr. Graham is at present conducting Dr. Hamilton's surgical clinic.

Dr. F. S. Whitman of Belvidere, Illinois, has been appointed to succeed the late Dr. Hamilton as Superintendent of the Elgin Asylum for the Insane.

Dr. E. C. Fortner, the County Physician, in his annual report points out the need in Chicago of a hospital for the treatment of alcoholic cases. At the Detention Hospital, where these cases are now treated, during the past year 501 women and 772 men, alleged to be insane, were tried. The court discharged 246, sent 600 to Dunning, 130 to Elgin, and 260 to the Kankakee Insane Ayslums, and 11 died.

During the past year the Warden of the Cook County Hospital, Mr. Graham, made a number of improvements. The new receiving ward was opened and put in service. It is fitted with every modern convenience and equipped with the best apparatus. The important feature among the improvements is the elaborate sterilizing plant with which the new operating-rooms have been equipped. The total appropriation for the hospital was $245,248. Of this $140,000 was expended for maintenance and supplies, and $105,248 for salaries. The number of patients admitted during the year 1898 was 18,283. The average cost per patient was 72.7 cents a day. The total number of employes was 225.

The daily average number of patients at the Dunning Asylum for the year 1898, was 1357; at the Infirmary, 1312, making a total daily population of 2669. The cost of maintenance of the patients, without counting in the salaries of employes, is 18 cents a day; adding the cost of salaries the daily average expense is 28½ cents per capita. Out of a total appropriation of $337,161 for the year, $276,420 was expended, making a saving of $60,740.

The City of Chicago has maintained its remarkable record for healthiness during the year. Notwithstanding the ominous appearance of two epidemic diseases much dreaded by sanitarians and health officers, namely, influenza and cerebrospinal meningitis, both during the first five months, the Commissioner of Health reports that the total deaths during 1898 were less than 1000 more than those of the previous year, when the mortality-rate was the lowest ever recorded for any city of more than half a million population. During the year the Municipal Laboratory, the work of which has come to be generally recognized as the backbone of effective sanitary administration, has been moved into more commodious quarters, its equipment largely increased, and its facilities improved in every respect. With this change and improvement has come a more than corresponding increase in the volume and variety of the work performed. Demands from the public for its skilled examinations of food-products and for its new and unobjectionable methods of disinfection, and especially from physicians for assistance in the recognition and control of the contagious and infectious diseases, are steadily increasing. All this has been made possible by the wisdom and foresight of the City Council for the maintenance and extension of the work.

Among the improvements effected during the year in the different branches of the Health Department may be noted the supervision of the cemeteries and undertakers as to burials, and of certificates of death as to causes, whereby it is made more certain, on the one hand, that no unauthorized burial or removal of a dead body may take place, and, on the other hand, that the true cause of death shall be reported in all cases. This rigid supervision has added greatly to the value of the vital statistics of the department.

The results of other improvements steadily pushed during the year are to be seen in the reduction in the deaths from contagious diseases generally, due to supervision of contagious disease funerals and other measures enforced to prevent the spread of such diseases; in the lowest actual number of deaths from diphtheria in any year since 1884, and the lowest death-rate of this disease among the patients treated by the department physicians, ever recorded in any community; in the lowest summer death-rate on record among infants and young children; in the more active cooperation of members of the medical profession with the department, and in the increasing confidence in the efforts of the department, encouraged and supported by the civic administration in all its branches, to safeguard effectively the interests of life and health in the community.

At a meeting of the Chicago Medical Society, held January 4, 1899, Dr. Homer M. Thomas read a paper on "The Mechanism of Nebulization in the Treatment of Pulmonary Tuberculosis."

He referred to the general interest which is taken in the subject of nebulization at the present time, and particularly its application to the treatment of pulmonary

troubles. Nebulization is one of the oldest propositions in treatment known to medicine. It traces back to the time of Hippocrates, who was the first to devise an apparatus for the purpose of inhalation. The evolution of nebulization has been greatly enhanced by the production of an oily menstruum, particularly the oils of the coal-tar products, which, as vehicles, may be used in combination with the stronger basic oils for inhalation. A difficulty which has appeared to lie in the direction of this treatment has been in the imperfect construction, and hence inefficient action, of various nebulizing instruments. Dr. Thomas described in detail a nebulizer which he has devised for his own use, and which has proved eminently satisfactory.

The latest addition to facilities in Cook County for treating disease has been the erection of a consumptive hospital at Dunning, which is devoted exclusively to the care and treatment of tubercular patients. One of the measures used in treatment is nebulization of the essential oils, as oil of cinnamon, oil of wintergreen, oil of pine needles, Merck's oil of cloves, oil of eucalyptol, beechwood creosote, and thymol. The compressed-air mechanism in the new hospital is probably the most complete in this part of the country. Extreme care has been used in providing absolutely pure air for the application of this treatment there. The air first enters the building from the highest ridge of the roof; it is filtered through three screens of increasing fineness; it passes into an antiseptic chamber, and then into a water bath, the water of which is filtered and chemically pure, and the water drops down through the compressed air as it passes through for the purpose of separating from it any possible impurities that may have escaped the former methods of purification and antisepsis. It is then carried from the water bath into a large tank of 150 gallons capacity, is stored at a pressure of 45 to 50 pounds to the square inch, it passes through another antiseptic chamber, and is then ready to be piped throughout the building. The capacity of the hospital is about 380 patients and with the present piping arrangement it will be possible to nebulize at the bedside probably 50 or 60 patients' special nebulæ as may seem needed for each case. In addition, there are rooms large enough to accommodate 10 or 15 patients at a time in which the air is supersaturated with antiseptic nebulæ. In these rooms the patients gather for from fifteen minutes to thirty or forty, and breathe this highly charged antiseptic air. By this means it is hoped, with the very efficient mechanical appliances there in operation, to greatly assist in the amelioration and possible extinction of pulmonary tuberculosis.

In the discussion on Dr. Thomas' paper, Dr. George W. Johnson stated that from June 1, 1897, to October 1, 1897, he persistently treated 260 tuberculous patients by the inhalation of vaporized oils, such as beechwood creosote, oil of cloves, and eucalyptol, using albolene as a vehicle. These oils were vaporized by compressed air (hydrostatic) of from 15 to 25 pounds pressure per square inch. The vapors were respired from a mask fitting tightly over the face and for a period of fifteen minutes each morning and evening. While inhaling the vapor the patients were required to breathe as deeply as possible and about the normal number of respirations per minute. From these 260 patients a careful clinical record of 40 cases was kept on such points as quantity and character of sputa, microscopic examination, temperature, pulse, respiration, cough, night-sweats, physical examination, and body weight. A study of this clinical record for four months showed good results. In each case the weekly examination of the sputa showed a marked diminution in the number of pus-cocci, but no appreciable diminution in the number of tubercle bacilli. The sputum was diminished in quantity, the cough greatly allayed, the body weight increased, with marked relief from night-sweats and dyspnea. The patients took kindly to the treatment. From October 1, 1897, to October 1, 1898, he had admitted to his tubercular ward 333 patients. Of this number 236 were given the vapor treatment persistently and 118 were so much improved that they left the institution to seek employment. He is of the opinion that inhalation therapy has a bright future.

OUR LONDON LETTER.

[From Our Special Correspondent.]

CHARACTERISTIC TRAITS OF THE LATE SIR WILLIAM JENNER—A SET-BACK FOR THE CHRISTIAN SCIENTISTS—A POWERFUL ALLY FOR THE VEGETARIANS—RADICAL TREATMENT OF HERNIA IN THE BRITISH ARMY.

LONDON, December 31, 1898.

THE death of Sir William Jenner is the principal subject of interest among the profession here at present. It was in no sense a surprise as he withdrew from all practice on account of failing health nearly nine years ago, at the age of seventy-four. In the eye of the public his principal distinction lay in the length and importance of his services as Court Physician for the term of no less than 32 years. He attended the Prince Consort in his last illness and the Prince of Wales in what very nearly proved to be his, in 1872. For days the royal patient hovered between life and death and so constant and assiduous were the attentions of his physicians, that he was popularly believed to have been saved only by one of them breathing into his mouth for several hours! Curiously enough the disease in both father and son was typhoid fever. Not only had Jenner the absolute confidence and warm regard of his illustrious patients (Her Majesty was pleased to allude to him in the last Court Circular as "not merely a most skilful physician, but a true and devoted friend," considered here a wonderful piece of condescension to a mere medical man) but of the profession as well. In fact, the best thing about his long tenancy at this distinguished position was that it was not due in any way to self-seeking, ambitious scheming or subserviency of any sort. Upon one occasion the Queen foolishly wrote to him expressing her deep regret that one with whom she was so intimately connected should have publicly upheld and endorsed the cruel practice of vivisection. Jenner promptly replied that he was sorry to pain Her Majesty by incurring her disapproval, but that he

felt under obligation to follow his own best judgment and conscience in such matters and if she felt in any way dissatisfied, his resignation was before her for action at any time. The matter was dropped at once and no further intimations of the sort were attempted again.

To the profession Jenner was best known by his splendid work as a teacher in the Chair of Principles and Practice of Medicine in University College, which influenced such men as Lord Lister, Sir Russell Reynolds, Sir William Roberts and Michael Foster, all of whom were among his pupils. His memory will live chiefly in his classic monograph differentiating typhus from typhoid. He was very proud of his descent from the same family as the great discoverer of vaccination.

Another decision has just been rendered which is of much importance in its bearing upon both Faith-Healing and Christian Science. It was given by no less an authority than the Lord Chief-Justice himself upon an appeal from the decision of a lower court. The plaintiff, a member of the sect known as "Peculiar People," had permitted his five-months' old child to die of bronchitis without summoning medical aid. He had followed scriptural injunction and had the child anointed with oil and prayed over by the elders of his church, also hiring a nurse to attend it. His counsel claimed that having done everything which he conscientiously believed to be necessary, he could not be held guilty of neglect. The Chief-Justice gave judgment at once upon the agreed statement of fact without calling for argument from the prosecution. He held that no matter what the father might have done or how devoted in other respects he might be shown, if he had deliberately failed to do the one thing which the unanimous experience of the race had shown to be of greatest value and importance in such circumstances, he was guilty of wilful and criminal neglect. As for the plea of religious or conscientious scruples (and here the decision is of special interest from the fact that Lord Russell is a devout Catholic), that, however valid in morals or theology, could not be entertained for a moment in a court of law, as otherwise the door would be opened for the gravest and most serious abuses. Nothing but absolute physical inability could excuse any man in the eye of the law for failure to use every common and well-attested means for the protection of the lives of those under his care.

The finding of the lower court was therefore sustained and the prisoner was taken back and next day sentenced to four-months' hard labor. It is to be hoped that this authoritative decision will govern the action of all judges before whom such cases are brought in future instead of the flabby invertebrate policy which has hitherto been pursued.

Dr. Alexander Haig's new book on "Diet and Food" ought to bring as much consolation to the vegetarian crusaders as it brings dismay to his friends. Not content with a moderate application of his really most ingenious and interesting theories and experiments upon the uric-acid factor in disease, he has overleaped all bounds of discretion and now attributes almost every evil that the flesh is heir to, moral as well as physical, to this baneful excretion. Suicide is more common in men than in women, because the former eat more meat! The gentler sex come in for their share of disaster in that chlorosis is due to the same dietetic vice. He even goes so far as to declare that "In diet lies the key to nine-tenths of all the social and political problems of our time." Truly uric acid is the root of all evil. Holding rigidly to his childishly inadequate and unchemical theory that the only source of uric acid in excess, in the body, is that actually taken in in the food, he naturally taboos every food-substance containing it in any considerable quantity; and falls at once into the vegetarian camp.

Even here, however, he cannot rest easy, but lays about him right and left because the vegetarian although avoiding the chief source of ready-made uric acid, still indulges in eggs which are bursting with it, and coffee and tea which consist almost exclusively of it in the easily convertible form of caffein.

Like most men who experiment chiefly upon themselves he has become almost hysterical in his extremeness. At this rate we shall soon be as purely and peaceably vegetarian as sheep and about as interesting.

The last Harveian lecture was delivered last week by Dr. William Ewart upon "Medical Education and Medical Practice: Their Pressures and Their Prospects." He paid a high compliment to America for her progressiveness in recognizing the value of clinical laboratories and for the high standard of public opinion in the prompt recognition and early treatment and avoidance of disease. The most serious problem approached by him was that of contract medical practice or clubs which not only guarantee to their members all professional services required for the disgraceful subscription of *eighty-seven cents* per annum but also employ agents to canvass for members and thus attack the poor doctors' remaining private patients. In some districts nearly two-thirds of the population belong to such clubs and practitioners all over the country are finding the situation a most serious one. Bht as yet no adequate remedy seems to have been devised.

The radical operation for hernia has just been recognized by the Army authorities and a circular issued urging all enlisted men with rupture now in the service, which are considered suitable for operation by their regimental surgeon, to repair to certain specified military hospitals where surgical experts have been detailed to perform it. In future no soldier will be invalided permanently for hernia, unless this operation has been tried or is judged inadmissible.

At the last meeting of the Medico-Chirurgical Society an elaborate paper was presented upon "An Improved Method of Treatment of Separation of the Lower Epiphysis of the Femur" by Jonathan Hutchinson, Jr., and H. L. Barnard. The authors had been fortunate enough to have the care of four cases of this rare fracture, in all of which the method gave excellent results. The difficulty in these cases has always been, first, in reducing the fracture and, second, in keeping the fragments in place on any ordinary splint. Out of thirty cases collected only six patients recovered with a useful limb.

The new method solves both difficulties by completely flexing the joint, when the fragments slip readily into place, and then retaining it so by bandaging the leg to the thigh for ten days or two weeks. By this time fair union will have occurred and the limb can be placed upon a Macintyre splint and gradually straightened with the screw-threads. This curious position is said to be well borne by the patient. Skiagraphs were shown of all the cases treated both before treatment, showing clearly the position of fragments, epiphysis forward, shaft backward, and after the excellent results of the method.

An ingenious representative of the *Lancet* is securing some interesting information upon the abortion question "from the inside" by writing to the advertisers of abortifacients and representing himself as a pregnant woman, and ordering supplies of their remedies. If they advise stronger preparations at higher prices, as they usually do, he again "bites" and purchases, and then analyzes all the stuff sent him. The composition ranges so far all the way from dangerous savin oil to innocent rue and senna tea in quart bottles.

TRANSACTIONS OF FOREIGN SOCIETIES.

MISTAKING TUBERCULOUS PERITONITIS FOR ACUTE INTESTINAL OBSTRUCTION—CEREBELLAR ABSCESSES FOLLOWING MASTOID DISEASE—ORIGIN OF LIPOMATA—DIAGNOSIS OF ACTINOMYCOSIS—PNEUMONIA WITH MULTIPLE FOCI—BILIOUS FEVER WITH HEMOGLOBINURIA—GLYCOSURIA IN PREGNANCY—SERUM DIAGNOSIS OF GASTRO-INTESTINAL CATARRH—SERUM DIAGNOSIS OF TUBERCULOSIS—CURE OF KELOID BY INJECTIONS OF CREOSOTE OIL.

AT the Surgical Society, November 23d, QUENU spoke of the possibility of mistaking tubercular peritonitis for acute intestinal obstruction or for appendicitis. One patient, a woman from whom he had removed both tubes and ovaries for tuberculosis, developed such sudden symptoms of stoppage of the bowels that he thought the small intestine was obstructed by an adhesion. Laparotomy showed that there were no adhesions, but that the peritoneum was thickly studded with minute tubercles. The operation was terminated, and the symptoms of obstruction vanished but the patient died soon afterward from extension of the tuberculosis. In another case obstructive symptoms came on suddenly in a little girl, the pain being referred to the right iliac fossa, so that the diagnosis of appendicitis was made. The usual incision for that trouble permitted the escape of some fluid and showed the peritoneum to be tubercular. This patient died two days later with symptoms of meningitis.

BRUM said that he had twice operated upon children having tuberculous peritonitis, under the supposition that they were suffering from acute appendicitis. Both patients recovered their health.

POTHERAT, BROCA and TUFFIER mentioned similar instances in which the diagnosis between acute intestinal obstruction and tuberculous peritonitis was made, either with difficulty or not until operation. In one of BROCA'S patients there was present obstruction by a band, as well as tubercular lesions. Appendicitis in another patient was mistaken for tuberculosis until it was too late. Most of the mistakes in diagnosis occurred in young children.

At the session of November 30th, QUENU spoke of two cases of non-union of fractured bones, in which union was secured after the administration of thyroidin. One of these patients was myxedematous after thyroidectomy.

RECLUS used thyroidin with success in a case of non union of six-months' duration, but it failed in his hands in two other cases.

PICQUE reported a case of cerebellar abscess following mastoid trouble in a child four years of age. He classified such abscesses as antero-internal, antero-external, and postero-internal. The last is much the rarest form of the three. They are best attacked by a temporo-occipital craniectomy which exposes the abscess in no matter which of the three situations, while the partial mastoid resection of Wheeler, or the total mastoid resection of Mignon, often give insufficient opportunity to get at the abscesses in the anterior situations, and fail utterly when the pus is situated in the posterior regions.

GUINARD and BROCA expressed a preference for the mastoid route, unless a diagnosis of posterior cerebellar abscess could be definitely made out before operation.

At the session of December 14th, TUFFIER showed a specimen which he had removed from beneath the clavicle of a woman aged twenty-seven years, where it had been growing six years. Besides the fatty lobules there were in it, calcified portions which examination showed to be due to an affection of a lymphatic gland. The specimen seemed to afford evidence in support of the recently advanced theory, that lipomata are due to inflammation of lymphatic glands, a true lipomatous periadenitis.

DELBET mentioned the occurrence of lipomatosis about lymphatic glands in such a manner that each gland was encircled by a thick layer of fatty tissue. Fat tissue develops similarly in the abdomen about the kidneys, bladder, rectum, etc., but such fat cannot be differentiated from true lipomata, and under conditions which waste the general tissues of the body, it holds its own, acting in this respect the part of a tumor. These perivisceral lipomata are probably of inflammatory origin, as are many lipomata which are found upon artisans at points where they are subjected to repeated contusions. There is, however, another distinct group of lipomata, which are congenital in origin, and often associated with angiomata. The term adenolipoma is an unfortunate one, since it suggests an adenoma rather than an inflammation of a gland, and it is better to use the term lipoma of inflammatory origin. The perivisceral fat tissue may be less definitely encapsulated and of greater fibrous consistence than the tissue of the common lipomata, but these distinctions are variable ones, for lipomata of all grades of encapsulation and firmness occur.

LEJARS thought that there is a great difference between the ordinary lipomata and symmetrical lipomatoses which in their growth can assume a certain degree of malignancy.

PONCET said that the diagnosis of actinomycosis can

be readily made from the clinical characteristics, and that one ought not to depend on microscopical diagnosis alone, for many times it is difficult to find the characteristic fungi, and if the microscopical diagnosis alone is considered, many cases of undoubted actinomycosis will be allowed to slip away unnoticed. His experience led him to believe that the disease is far commoner than is generally understood.

At the Medical Society of the Hospitals, November 25th, DUFLOCQ described a case of pneumonia with multiple foci, there being no less than nine of these in the lungs, and five in the rest of the body as follows: a suppurative arthritis of the right shoulder, a prelaryngeal abscess, an inflammation of the inguinal and crural glands, a suppurative psoritis, and finally, a meningitis. Pneumococci were demonstrated in these various foci, and were also found during life in the blood.

At the session of December 2d, VINCENT read a paper on the etiology of bilious fever with hemoglobinuria. Most writers assume that hemoglobinuria is due to malaria. In five cases which had recently come under his notice he had never been able to find any organisms in the blood except in one instance when an ameba was present. The patients had an intense fever with jaundice and bilious vomiting. Moreover, sulphate of quinin is useless in such cases. Two of the five patients referred to died, and three recovered. In paroxsymal hemoglobinuria, so-called, the occurrence of a chill is often said to produce the hemoglobinuria; but in the disease under discussion, such did not seem to be case. Koch and others have asserted that the condition can be produced by the quinin which has been taken to ward off or to cure malaria; but this view does not seem to be well founded. The clinical character of the affection, and the epidemicity which it sometimes manifests, leads one rather to the opinion that it is of an infectious nature.

At the Biological Society, November 26th, BROCARD spoke of the glycosuria of pregnant women, of whom he had examined 125, finding that sugar existed in the urine of sixty of them, that is to say, in about fifty per cent. of the cases. The presence or absence of sugar was variable, being influenced by the diet, the time of day when the water was passed, etc. Glucose and lactose were the sugars usually found, saccharose and levulose being present only occasionally. In many instances in which no sugar was found in the urine, it would appear if the patient took 50 to 100 grams (1.5 to 3 ounces) of sugar. Why should the ingestion of this small amount of sugar give rise to glycosuria? An attempt has been made to explain this fact by saying that the hepatic action was insufficient, but glycosuria occurs in women whose livers are acting perfectly as far as one can observe. The glycosuria of pregnancy is rather to be attributed to a disturbance of the general nutrition.

NOBECOURT reported experiments made to determine in attacks of gastro-intestinal trouble in infants due to the colon bacillus, whether or not there is a specially virulent colon bacillus which is the cause of the inflammation. He found it impossible to settle this question by methods of agglutination, since the serum of patients who had virulent coli bacilli in their stools, failed utterly to agglutinate these bacilli, while the serum of those patients whose stools contained non-virulent coli bacilli frequently exerted a weak agglutination upon such bacilli. In other words there is no such thing as a serum diagnosis of gastro-intestinal infections. Experimental serums, obtained after inoculations with the same virulent coli bacilli, had an agglutinative power, each for its own colon bacillus, but not for others equally virulent, obtained from the diarrheic stools of other infants in the same locality and place, so that it is equally impossible to speak of a special sort of colon bacillus which is responsible for gastro-intestinal affections of infants.

WIDAL said that the serum reaction for coli bacilli in man does not possess the value which that for typhoid bacilli possesses, because the different specimens of coli bacilli obtained from sick or healthy individuals, in spite of their similarities, are, nevertheless, distinct. The clinical results are quite in accord with this statement. It was at first reported that a serum diagnosis was possible in four-fifths of the cases of gastro-intestinal catarrh, but more careful investigation has shown this to be much overstated. The speaker agreed with Nobecourt that there is no special kind of colon bacillus which produces gastro-intestinal infection, and that the serum diagnosis of cases of this disease is worthless.

December 10th, MONGOUR and BUARD stated that a sharp agglutination was caused by the serum of four patients suffering from serous and hemorrhagic pleurisy, undoubtedly tuberculous, as well as by the serum of nine phthisical patients. Twenty other patients ill with various maladies (epilepsy, rheumatism, bronchitis, scarlatina, typhoid fever, etc.) were subjected to examination by the serum method, and a positive result led to the discovery of latent foci of tuberculosis in them which had not before been suspected. The greater the resisting power of the patient, and the less his cachexia, the more sharp was the agglutinative reaction.

At the Society of Dermatology and Syphilography, December 8th, BALZER described the result of injections of oil containing 20 per cent. of creosote for the cure of keloid in a girl aged sixteen years. The child was of a strumous diathesis and her brother had died of tuberculosis. She had two keloids, presumably tubercular, recurrent in the scar following the removal of a tumor, probably lupus. One c. c. (15 drops) was injected, several punctures being made. Owing to the density of the tissue some of the fluid exuded. The pain was slight, but the inflammatory reaction the following day was severe, and was followed by the disappearance of a considerable portion of the growth. The ulcers which formed healed readily. After four treatments the smaller of the keloids had disappeared entirely, while the larger persisted after nine injections, although greatly reduced in size.

REVIEWS.

THE HYGIENE OF THE VOICE. By THOS. F. RUMBOLD, M.D. St. Louis: Witt Publishing Co., 1898.

THIS little monograph was evidently written for sing-

ers and, probably, to some extent, for physicians. Besides enumerating a number of annoying functional and organic troubles that may afflict speakers and singers, the author presents a horrible picture of the effect of tobacco upon the respiratory mucous membranes, devoting one paragraph to show how smokers may be detected after death. The bookmaking is something to shudder at.

A COMPEND OF DISEASES OF THE SKIN. By JAY F. SCHAMBERG, A.B., M.D. Philadelphia: P. Blakiston's Son & Co., 1898.

THIS little work, which constitutes the dermatological volume in the publisher's series of Quiz-Compends, will undoubtedly prove one of the most valuable of the series. The subject of dermatology is so much neglected at our schools, and its presentation to the student, moreover, rendered so difficult and complex that the undergraduate will surely welcome the admirably clear and concise synopsis here presented.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. By JOHN B. SHOEMAKER, M.D., LL.D. Third edition. New York: D. Appleton & Co., 1898.

THE third edition of Dr. Shoemaker's well-known textbook constitutes a welcome addition to the works on dermatology. The previous editions of the book are so well known to the profession and have been so favorably received that any words of commendation would appear superfluous. The work is particularly rich in formulas for the internal and external treatment of skin diseases and will be valued especially by all those who share the author's therapeutic enthusiasm. Paper, presswork, and typography are of a high standard of excellence.

TRAITE DE MEDECINE ET DE THERAPEUTIQUE. Publie sous la direction de MM. P. BROUARDEL et A. GILBERT. Tome cinquième. Paris: J. B. Baillière et Fils.

THE fifteenth volume of this system embraces the diseases of the salivary glands, of the pancreas, of the liver, the spleen, the kidneys, and of the male and female generative organs. The widely known views of the French school on therapeutics and pathology are found emphasized, although credit is given to German investigators and clinicians. The chapters on gynecology are wofully deficient, while those on diseases of the other abdominal organs are fully and thoroughly treated. The work is one for reference only.

THE CARE OF THE BABY. A Manual for Mothers and Nurses. By J. P. CROZER GRIFFITH, M.D., Clinical Professor of Diseases of Children, University of Pennsylvania. Second edition. Philadelphia: W. B. Saunders, 1898.

THERE are many, many things in this splendidly written book that tend to make the treatment of sick children easier for the physician, and that will aid a mother in keeping her children out of the doctor's hands. The element that predominates is one of common sense based upon experience. Here one finds all that concerns the child from the time of its birth to the hour of its beginning education, and it is safe to assume that a child handled in the manner indicated in Dr. Griffith's book will be a splendid specimen mentally and physically. Although the book is intended primarily for mothers and nurses, there is much in it which the average physician does not know and might know to the advantage of his patients.

THE POCKET FORMULARY FOR THE TREATMENT OF DISEASES IN CHILDREN. By LUDWIG FREYBERGER, M.D., Vienna; M.R.C.P., London; M.R.C.S., Eng. Clinical Assistant, Hospital for Sick Children, Great Ormond street; Curator of the Museum, Pathologist and Registrar, Great Northern Central Hospital, London. London: The Rebman Publishing Co., Ltd., 1898.

THIS little book will be found helpful in prescribing for children. It contains a brief account of the properties and the general and special therapeutic uses of drugs, old and new, which have been proven valuable in the treatment of children's diseases. A large number of formulæ is given, many of them being credited to eminent authorities. Incompatibles, antagonists, and antidotes are noted, and careful mention is made of the correct dosage for different ages, and also of the exact amount needed of the flavoring agent which will best disguise an unpleasant taste or smell. Lists of preparations suitable for local and hypodermic medication are appended. The book is clearly printed and conveniently indexed.

THERAPEUTIC HINTS.

For Gastric Fermentation, due to gastrectasia, or pyloric stenosis:

℞	Resorcin	ʒ ss
	Bismuthi subnitratis	ʒ iiss
	Aq. dest.	℥ iii.

M. Sig. One teaspoonful in a glassful of water half an hour before meals, three times a day. (Shake the bottle before using.)—*Einhorn.*

For Uric-Acid Diathesis.—For such patients the following mixture is recommended by GOLDING BIRD:

℞	Sodii bicarbonatis	gr. xlv
	Ac. benzoici	gr. xv
	Sodii phosphatis	gr. lxxx
	Aq. bullient	℥ iss.

M. Dissolve and add:

	Aq. cinnamomi	℥ iii.

Sig. Two teaspoonfuls three times a day.

To Prevent Vomiting after Eating in Tubercular Patients.—MATHIEU claims that the administration of menthol as given below will limit or entirely prevent the occurrence of the coughing spells which follow ingestion of food, and frequently induce vomiting:

℞	Menthol	gr. iv
	Syr. simplicis	ʒ i
	Mucil. acaciæ	℥ iii.

M. Sig. Two to four teaspoonfuls at intervals after meals.

THE MEDICAL NEWS.
A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIV. NEW YORK, SATURDAY, JANUARY 21, 1899. NO. 3.

ORIGINAL ARTICLES.

GONORRHEAL ARTHRITIS.

BY A. BRADLEY GAITHER, M.D.,
OF BALTIMORE, MD.

IN 1781 the extended article of Swedaiur called the attention of the medical profession to the fact that a peculiar form of rheumatism often existed during cases of urethral discharge, but many years passed before it was recognized that the gonorrhea should be looked upon as the cause of the inflammation in the joint. The discovery of the gonococcus by Neisser in 1879 at once gave rise to various theories as to the cause of gonorrheal arthritis. One school held that it was due to the gonococcus itself; another, that pus micro-organisms, which obtained entrance through erosions in the urethra, produced by the gonococcus, were the cause of the disease; a third, that it was the result of a mixed infection; a fourth, that a toxin, produced by the action of the gonococcus on the mucous membrane of the urethra, should be considered as giving rise to the articular symptoms.

That the fluid drawn from the synovial membrane often did not contain gonococci was brought forward as a proof that their presence was not essential at the point of inflammation, the possibility of the death of the gonococcus before the joint had been tapped being ignored. However, it was generally acknowledged that the disease did not exist with non-specific urethritis, and, on the other hand, was present in cases of gonorrheal ophthalmia, consequently something more than a mere irritation of the mucous membrane was necessary. It was also admitted that patients subject to ordinary articular arthritis did not show any predisposition to gonorrheal arthritis, while those who had suffered from the latter disease seemed especially liable to another attack should they acquire a fresh case of gonorrhea.

Höck, in 1893, and Neisser, in 1894, demonstrated positively the presence of the gonococcus in the effusion drawn from a joint affected with gonorrheal arthritis, and thus placed the pathology of the disease on a solid basis. Bordone-Uffreduzzi, in 1894, furnished the positive clinical and bacteriological proof that the disease is due to the gonococcus by making cultures from an ankle-joint, and producing specific urethritis in a healthy urethra by inoculation with the pure cultures. But the presence of the gonococcus in the blood-stream had not yet been proved, although it had long been maintained by many authors.

Assuming that gonorrheal arthritis is due to the direct entrance of the gonococcus into the circulation, one of two conditions must exist in order to harmonize with the symptoms of the disease: as only one joint is generally affected, the cocci must be present in the blood-current in very small numbers or the power of resistance of the membranes and tissues must be comparatively less. As a matter of fact, the gonococci found in an inflamed joint are rarely present in such numbers as would be expected, showing that the media in which they are growing is not especially congenial, or that the virility of the coccus has been diminished in its transplantation. Finger claims that the gonococcus can cause suppuration in the connective tissue. If this be accepted as true, it is surprising that its presence in the blood does not produce greater destruction of tissue than has been observed, and that the inflammatory foci set up are comparatively so few and also are so widely separated.

The presence of gonococci in the blood-stream has been proved by Thayer and Bloomer in an article on "Ulcerative Endocarditis Due to the Gonococcus."[1] The case was that of a female, aged thirty-four years, who had been suffering from an endocarditis of unknown origin. Gonorrhea was not suspected. During life, blood was aseptically drawn from the median basilic vein and mixed with agar-agar, the proportion of blood in the plates being at least one-third, which combination is practically Wertheim's medium. After forty-eight hours in the thermostat the plates were found crowded with white pin-head colonies. Cover-slips from these colonies showed a small oval diplococcus, at times biscuit-shaped, the elements being side by side. Transplantation on agar-agar, gelatin, potato, litmus milk, and bouillon were negative, no growth resulting. At the autopsy there was found an acute ulcerative endocarditis, with a diplococcus present in the valve, which, under similar tests, proved identical with that obtained from the blood during life. Examination of the vaginal secretion made after death showed a diplococcus, decolorizing by Gram's method. The authors believed that the diplococcus found in the case was the gonococcus of Neisser for

[1] *Johns Hopkins Hospital Bulletin*, April, 1896.

the following reasons: (*a*) Its form and arrangement were characteristic; (*b*) while present free, the cocci were frequently found crowded in the protoplasm of leucocytes in the thrombus on the valve; (*c*) it refused to grow on ordinary media; (*d*) it grew readily on human blood-serum and agar-agar (one-third blood); (*e*) it decolorized when treated by Gram's method.

The results obtained from this case prove beyond any reasonable doubt that the gonococcus can be present in the blood stream, thus giving a satisfactory explanation as to the manner in which the coccus is transferred from one portion of the body to another. The gonococcus enters the circulation through ulcerations in the urethra. The tissues beneath the epithelium of the urethra are often invaded, and sections have shown the smaller capillaries filled with gonococci, thus giving positive evidence as to the manner in which they may gain entrance into the blood-stream. Crippa reports a case of gonorrhea, of two-days' duration, in which there was marked edema of the frenum. The edematous areas were punctured, and gonococci were found in the fluid obtained. This discovery offers an explanation as to the mode of infection in those rare cases of gonorrheal arthritis which develop within a few days after the appearance of the urethral disease.

Cases of gonorrheal arthritis have been classified into serous, serofibrinous, seropurulent, and purulent synovitis, the names applied expressing the character of the contents of the joints. The serous and serofibrinous are the milder and more frequent forms of the disease. They generally end in complete resolution, with a gradual return of unrestricted motion. Every recurring attack seems to take a more severe form, and a third or fourth infection will almost certainly result in permanent disability. Dr. Broadhurst reports a case in which the patient had suffered three attacks of gonorrheal arthritis, each one preceded by acute specific urethritis. The attacks were progressively more severe, and after the last there remained some stiffness which appeared to be more muscular than articular. The man married, and was shortly afterward seized with acute inflammation of every articulation, resulting in ankylosis, which left him practically ossified, without power to move his head or any limb, and unable even to masticate his food. Purulent synovitis fortunately is rare. It often results in the complete destruction of the joint affected, sometimes necessitating resection or amputation. It is generally impossible to decide which variety of synovitis is present until after the joint has been opened, and in the early stages the treatment is the same under all circumstances. If there have been mild recurring attacks of serous or serofibrinous synovitis, a chronic condition of hydrarthrosis will probably remain, but with favorable prospects for unrestricted motion.

The knee-joint is most frequently involved in gonorrheal arthritis, furnishing about one-half of the cases. Next in order follow the ankle, shoulder, and hand. Fournier collected reports of 120 cases. The number of joints affected was 212. The knee was affected in 83 cases (more than two-thirds), the ankle in 32 (about one-fourth), and the fingers and toes in 25 (about one-fifth). The disease is present in two per cent. of all cases of specific urethritis in males, but is rarely found in females. A man of such large experience as Foucart says that he never saw a case in a woman.

Instances have been reported in which gonorrheal arthritis developed within a few days after gonorrhea was contracted, but, as a rule, it appears between the third and fifth weeks. It may, however, develop after months, as a result of chronic posterior urethritis, and the patient cannot be considered as having escaped this complication until it is positively known that the urethra no longer contains gonococci. Acute gonorrheal arthritis, whether monarticular or polyarticular, begins with a feeling of dull pain in one or more joints, followed quickly by redness and swelling, as the inflammation increases. Pressure over the tendons and insertions of the ligaments give pain before effusion has taken place. There is a rise in temperature, possibly as high as 104° F., but generally there is a marked contrast between the amount of swelling or pain and the temperature. Effusion occurs rapidly, the tension produced aggravating the pain. Extension of the inflammation along the muscle-sheaths prevents motion, and causes pain to be felt above and below the joint. In a few days the temperature drops to nearly normal, rising again if a new articulation becomes involved. Although the tension in the joint may become so great as to make suppuration seem inevitable, as a rule it does not take place, and the disease shows a tendency to become chronic, with occasional acute exacerbations. The endocardium and pericardium are not involved as frequently as in articular rheumatism. The urethral discharge is not diminished or suppressed by the appearance of the arthritic complication.

In chronic gonorrheal arthritis or hydrarthrosis, the invasion may be so slow and the constitutional affection so slight, that the first symptom which attracts the patient's attention may be the swelling and restricted motion of the joint. The knee, ankle, and elbow are usually affected. Absorption, as a rule, is very slow, and deformity may result

from adhesions due to inflammatory changes, or the exudate may develop organized fibrin, with resulting ankylosis of the articulating surfaces. In severe cases the synovial membrane may be thickened, while its inner surface becomes granular and pulpy. Erosion of the articulating cartilages and destruction of the bone substance, with separation of the periosteum, may completely destroy the joint, necessitating resection or amputation. The bursæ may undergo similar changes to those which take place in the synovial membrane of the joint. The most frequently affected is that in front of the tendo-Achillis, involvement of which gives rise to the characteristic limp, so often seen in cases of gonorrheal arthritis. The muscles of the neck and eye are at times involved, while affections of the spinal cord and sciatic nerve are by no means rare.

The diseases with which gonorrheal arthritis is most likely to be confused are articular rheumatism and tuberculosis of the joints. The persistence of pain in one articulation, the chronicity of the effusion, and the lack of conformity between the local lesion and the constitutional symptoms are the main differences from articular rheumatism. The diagnosis from tubercular inflammation is facilitated by the bacteriological examination of the contents of the joints, and of any existing urethral or vaginal discharge. In cases in which the result of such examination is negative, the differentiation is very difficult to make, especially in married women, with possibility of venereal disease contracted from the husband, and without a tuberculous history.

The treatment of gonorrheal arthritis has been most unsatisfactory, and will continue so until a means has been discovered for discouraging the development of the gonococcus, when once it has entered the circulation, or has been deposited in locations which cannot be reached by topical applications. White recommends quinin in doses of 5 to 10 grains, three times a day, and biniodid of mercury $\frac{1}{10}$ of a grain until improvement sets in. Mercury, in various forms, pushed to its constitutional limit, has been advocated by many authorities, and in some cases can be used to advantage. Copaiba, in large doses, and salol are also, at times, of great value. If the swelling and pain are great, the application of leeches may give temporary relief. The use of the Paquelin cautery, applied daily, is of benefit, especially in the subacute stage. Hot applications of a lead-and-opium solution may be used to alleviate pain, and the joint should be wrapped in cotton, bandaged lightly. If the case has become subacute or chronic, with delayed resolution and impairment of motion, massage, and particularly forcible, gradual flexion of the joints hastens the return of voluntary motion. Too much stress cannot be laid upon this point. By breaking up any adhesions before they have had time to become thoroughly organized, not only is the function of the joint restored sooner, but also possible permanent impairment of motion is prevented. Force, however, should only be used in flexion. If adhesions keep the joint in a position of flexion, the tendons should be severed before forcible extension is attempted. Surgery is being more frequently resorted to, and the aseptic opening of the joint, in severe cases, followed by irrigations with an antiseptic solution, is a rational and often most satisfactory procedure. If the arthritis is due to specific urethritis, the urethra should receive especial attention, and the patient should be warned, on his recovery, of the great danger of permanent disability should he again acquire gonorrhea.

The patients whose cases are here reported were treated by means of copaiba, 10 grains, cubeb, 5 grains, salol, 3 grains, and pepsin 1 grain. As constitutional effects of copaiba were present in both instances, it seems probable that the therapeutic results noted were due to this drug.

CASE I.—January 10, 1896. A. R., white, aged twenty-five years, had been suffering from specific urethritis six weeks. First attack. Slight burning on micturition. No increase in frequency. Discharge profuse and purulent. Had been treated with injections of sulphate of zinc. Two days before was taken with feeling of malaise, followed by slight chill. Temperature, 102° F.; pulse, 90. The joints of the second and third fingers of the right hand were slightly red, swollen, and painful, the articulation of the first and second phalanges of the second finger being especially sensitive. The hand was enveloped in cotton, and a bandage applied. Capsules of salol compound, one every three hours, was ordered. No injection was ordered, as the patient could not use a syringe on account of the condition of his hand. January 12th. Patient was in great pain, complaining of throbbing sensation in the right hand, especially the second finger, which showed effusion at the joint of the first and second phalanges. Skin covering the same was glistening. Could not bear weight of bedclothes on hand, or slightest draught from an open door. Hot lead and opium lotion applied every two hours. Temperature, 101° F.; pulse, 92. January 16th. Sixth day. Temperature, 100° F.; pulse, 84 in morning. In the evening a bright rash appeared over face, arms, body, and legs, which proved to be a well-marked copaiba erythema. Bowels slightly loose. From the moment the erythema appeared the symptoms of the arthritis improved, the pain practically disappearing in a few hours. The capsules were discontinued. January 18th. The fingers could be moved with almost no pain, and the swelling around the joints was less. The urethral discharge, which greatly dimin-

ished while the effect of the copaiba was at its maximum, returned as before when the administration of the drug was suspended. The gonorrhea lasted several months, with no return of the arthritis.

Case II.—March 10, 1897. W. F., white, aged twenty-four years, had had specific urethritis three weeks; second attack. No pain on micturition or increase in frequency. Discharge moderate and purulent. Four days before right knee became painful and enlarged. Was then markedly swollen, with slight effusion. Swelling pronounced on inner surface, extending along tendon-sheath above joint. Articulation of metacarpus and first phalanx of right little finger was swollen, red, and painful. Duration two days. The patient was ordered capsules of the salol compound, one every three hours, and an irrigation for urethra of bichlorid of mercury 1 to 40,000. March 12th. Patient had been compelled to go to bed on account of pain in knee. The joint was wrapped in cotton and hot lead-and-opium solution applied every two hours. Condition of right knuckle unchanged. Temperature, 101.8° F.; pulse, 80. Bowels very loose. March 14th. Condition improved. Knee not so painful. The diarrhea was so pronounced that the capsules containing copaiba were stopped and quinin and salol substituted. March 17th. Pain and swelling in knee much less. Temperature, 100.5 F.; pulse 80. Bowels regular. Capsules of salol compound were again administered, one every four hours. March 20th. Patient much improved. Pain in knee practically gone. Swelling less pronounced. The knee-joint was stiff and could only be slightly flexed. Temperature, 99° F.; pulse, 76. Massage treatment was given the knee every day, with gentle forced flexion, and as the effusion was absorbed voluntary motion gradually returned. The capsules were continued and on April 1st the man could walk fairly well. By April 10th, one month after the beginning of treatment, only a slight stiffness remained, and the urethritis having been cured in the meantime, the patient was discharged.

Both these patients seemed especially susceptible to the action of copaiba, and in both marked and continued improvement was noted as soon as the physiological effects of the drug were observed. There seemed to be an almost immediate relief from pain. Copaiba undergoes changes in the economy by means of which it becomes germicidal. Appenheim has shown that urine passed by a patient after the administration of 20 grains of copaiba sterilized silk threads charged with microbes. Since gonorrheal arthritis has been proved to be due to the transplantation of the gonococcus, the possibility that the systemic effect of copaiba may inhibit their growth or even prove germicidal, cannot be ignored. Although in the light of our present knowledge we are unable to make out a distinctly rational treatment for gonorrheal arthritis, copaiba, by the results obtained from its use, seems to have proved itself worthy of a trial.

PROTARGOL AND ARGONIN IN THE TREATMENT OF THE PURULENT OPHTHALMIA OF INFANTS.[1]

By EDWARD S. PECK, M.D.,
of New York;
Professor of Diseases of the Eye in the Post-Graduate Medical School and Hospital; Visiting Ophthalmic Surgeon to the City Hospital.

Since the introduction of silver nitrate in the treatment of gonorrheal catarrh, by Professor Neisser of Breslau, experiments have aimed at the eradication of the micro-organism characteristic of that infection. Previous attempts lay in the sole direction of arresting the profuse secretion, with the evident idea of the ancient metaphor—no secretion, no infection. Since Neisser's announcement of the gonococcus, about twenty years ago, efforts at replacing the silver nitrate by other agents have been made in the direction of those whose action is more bland, or less caustic. Condé's fluid, solution of potassium permanganate, cupric sulphate, zinc sulphate, mercuric bichlorid, chlorin, bromin, etc., have been in vogue, with the result that none of them has achieved the distinction of a *sine qua non* in ophthalmic practice. No remedy has accomplished what the silver nitrate has, *viz.*, to eradicate the gonococcus and to thus destroy the source of infection. In that most excellent paper of Weeks (1886) which aroused perhaps more earnest endeavor to establish the true germicidal remedy for this infection than any modern contribution in English, we are told the relative germicidal properties of the various remedies in ophthalmic practice employed in this and kindred conjunctival diseases. The silver nitrate holds the first position, but, unfortunately, it cannot be used in the strength of solution required on account of its severely irritating properties.

My only motive for presenting this brief paper is to emphasize the following points in connection with the two remedies, protargol and argonin, in so far as they seem to be superior to the silver nitrate; these points are: (1) the quicker destruction of the gonococcus; (2) the earlier disappearance of the secretion and the inflammatory process; (3) the resolution of the injured corneal and conjunctival tissues. A brief chemical review of these two agents is necessary in order to understand their clinical relations. Each is described as "a silver proteid compound, solutions of which cannot be precipitated by sodium chlorid, or by albuminous fluid." Protargol contains 8.3 per cent. of silver; it is a yellowish powder, readily soluble in cold as well as in hot water, forming a clear solution. It keeps well in powder form and in solution. Argonin contains 4.2 per cent. of silver. It is also a powder, fine,

[1] Read before the Section on Pediatrics of the New York Academy of Medicine, December 8, 1898.

white, readily soluble in water on gently warming, but its solution is turbid. Argonin decomposes if exposed to too much heat in the preparation of solutions, and when decomposed it is very irritating. It is said not to keep well in solution, even in dark-colored bottles. In this connection it should be noted that silver nitrate contains 6.35 per cent. of silver, occupying between protargol and argonin a middle position as to the basic salt.

I desire to quote the conclusions of a clinician as to argonin, who used only 2-per-cent.-solutions. "First, both experimental and clinical investigations have shown that argonin kills the gonococci in a short time, notwithstanding its lack of albumin-coagulating power. Second, even in solutions stronger than 2 per cent. it has hardly any tendency to set up inflammation and it has no caustic properties." Protargol is more painful, and does not require solutions stronger than one-half to two per cent.; it is more promptly germicidal, and it is less likely to irritate. The germicidal superiority of protargol over either argonin, or silver nitrate commends it especially in the disease under consideration. This, in brief, is a comparison of the clinical behavior of each salt.

In some of the cases observed by me the gonococcus disappeared as early as two weeks, and in none later than four weeks. The average persistence of the specific germ under the silver-nitrate treatment is about five weeks. In one case where the mother had the gonococcus of Neisser, and both eyes of the infant were affected, the duration was only two weeks; but the ophthalmia did not appear until the child was more than two-weeks old. On the other hand, the bacteria were abundant in both mother and child. This was one of those unusual cases in which the abundance of secretion did not carry with it virulence of infection; and the anomalous relation can only be explained by the late development of the ophthalmia. In the limited observations thus far made by me there has been less ulceration of the cornea, with iris-protrusion and incarceration, less corneal staphyloma, and less cicatrization of the conjunctiva than with the silver nitrate; in other words, a quicker eradication of the gonococcus, and an earlier disappearance of the secretion and inflammatory processes, have been followed by a prompter resolution of the injured cornea and conjunctiva, while pain and reaction have been much less under the protargol than under the silver-nitrate treatment.

Before giving in detail the method of employing these salts, it is pertinent to the purposes of this contribution to describe the gonococcus found in the gonorrheal ophthalmia of infants, and the method of preparation for microscopic observation. The bacterium which Neisser discovered in 1889, as distinctive of gonorrhea, was a diplococcus of about one micromillimeter in size, contained within a round pus-cell formation; this is the usual bacterium found in purulent ophthalmia, and it establishes the unfailing source of origin of the contagion. Fifteen to twenty cells on one slide under one-eighth immersion-lens with a No. 2 binocular would be regarded as a large number; this power represents about 750 diameters; cells containing from twenty to one hundred diplococci may be said to be rich in bacteria. Sometimes only one or two round cells are found with from ten to twenty diplococci contained in each, in which case the specimen may be said to be poor in germs.

There are other microbes than the diplococcus of Neisser capable of reproducing purulent ophthalmia. Weeks isolated a bacillus in 1886 capable of reproducing a contagious ophthalmia; this was the same bacillus noted by Koch in Egypt in 1883, but not renewed by culture or transmission. Gifford in Omaha, and Axenfield and Morax in Paris and Würzburg, and Burnett in Washington found not the diplococcus of Neisser, but the micro-organism of pneumonia. Morax in 1897 found a diplobacillus, which he regarded as essential to the production of a contagious subacute conjunctivitis. As stated, all of these varieties of germs have been found and cultivated, and from their cultivations purulent ophthalmia has been produced. While we are indebted to bacteriologic discoveries for the nice differentiation of these diseases, the last word has not been said as to the actual conditions under which micro-organisms act. There must be a proper habitat of connective tissue and mucous membrane for the full play of their specific qualities; and there is much to be learned.

The method of preparation is very simple. A loop of wire, preferably of platinum, made fast to a wooden handle, gathers up a bit of secretion from a lower lid; this is transferred to a glass slide, and a second slide is smeared upon the first, thus giving two surfaces for observation at the work-bench; these slides are separated from each other, and placed in a bath of Löffler's methylene-blue for one or two minutes; a stream of water is allowed to flow over the deeply-colored specimen, after which their surfaces are dried with white blotting-paper. Thus two specimens are ready for observation. They are best examined under immersion with oil of cedar, and with the power already noted. The presence of a single cell with diplococci means infection—and it often happens that repeated examination has to be made to verify the supposition of their presence.

The following process is given by F. Miehle[1] for

[1] *Pharm. Ztg.*, xlii., p. 817.

making solutions of argonin readily and rapidly: Ten parts of cold water are first introduced into a flask, and then one part of argonin. The whole is then vigorously shaken until a uniform mixture is had, when sufficient boiling water to make up the desired quantity of solution is added, the whole being frequently shaken until complete solution occurs, when the mixture is strained through a piece of gauze. The most effective solution of argonin for clinical work is one of 3 per cent. To prepare solutions of protargol the powder is stirred with some water, with or without the addition of a little glycerine, into a paste, and then diluted by adding the necessary quantity of cold or lukewarm water. Solutions of 0.25 to 2 per cent. are generally employed. A saturated solution of protargol is 50 per cent.

The method of using these solutions in a case of gonorrheal ophthalmia of an infant should be described at this point, as also the whole régime of the management of the patient. I may say here that such régime requires the skilled work of a trained nurse or nurses, in conjunction with the good judgment of a physician. The best type of régime is found in a well-regulated hospital; but the same details can be carried out in a private family, under similar skilled labor and good judgment. If one eye only be affected the fellow eye should be covered securely in every part, save at the lower outer region, over the temporo-malar portion of the orbit. This little opening is left for ventilation. The least harsh covering for a newly born infant's eye is lintine; this is cut round, slightly larger than the orbit; it is covered with a soft fluff of sterilized cotton; and this latter with gauze; collodion is smeared around the whole edge of the pad, save at the point already noted. This protected eye may be inspected every second day. The affected eye must be handled by the nurse from behind the patient's head; the nurse should never carry the infant in her arms; small round layers of lintine are transferred from a large square of ice every minute or two to the affected eye—and these minute changes are made for one hour without intermission; when an interval of one hour, or two or three, is given, according to the mild character of the affection. The rule is, however, to begin with continued applications of the ice-cold pledgets by day and night, the patient being under the care of two nurses. No interval of application should be ordered until there is positive evidence of an abatement of secretion; and this may not occur under two or three weeks; and it may result in a few days. The eyeball, lid, interspaces, and conjunctival sacs should at first be thoroughly irrigated with warm saturated solution of boric acid, the saturation-point of boric acid being about 4 per cent. As the secretion diminishes and gets shreddy, the nurse should wipe out the discharge with cotton dipped in the same boric-acid solution. Every effort should be made to keep the eye free from secretion. The protargol solution, at first 5 to 10 per cent. in strength, should be carried rather forcibly over the eyeball, and into the folds of the conjunctival sacs by means of a large pipette; it should at first be used from four to six times a day. As soon as the secretion lessens in amount, or becomes shreddy, while its fluid part becomes thinner, the protargol solution may be brought down to 2 per cent., and may be used less frequently. A successful result of such treatment would be a limitation of the disease to three, possibly, two weeks.

Examinations for gonococci should be made every second day, and an eye should not be regarded as safe, or as amenable to contact with its mother, until a full week has elapsed, in which absolutely no gonococci are found under the microscope. It must not be forgotten that, even with an apparently uninflamed eye, the sclera being white, the cornea glistening, and the lids scarcely swollen, gonococci may be present. The physician should not be too conservative as to the length of quarantine in a convalescing ophthalmia.

It is of great clinical advantage to know that protargol can be combined with many other salts, such as the sodium-chlorids, alkalies, etc.; it is unaffected by cocain, atropin, eserin, and other allied anodynes used locally in the eye; hence its field of usefulness in ophthalmia is very broad. It is not decomposed or precipitated by the albumin or alkalies present in the secretions from mucous membranes; and it may be stated that it is the only silver compound at present known which is not precipitated by dilute hydrochloric acid. I may add that its use in my hands in suppurations of the lacrimal sac, purulent styes, etc., has been more frequently followed by a checking of the pus-formation than when any other agent has been employed.

The following cases are quoted to show the advantage to be derived from the use of protargol in the treatment of gonorrheal ophthalmia. The results obtained show that the duration of the disease has been shortened, that gonococci have disappeared at an earlier date than usual, and that the sight of the affected eye has, to say the least, not suffered more than when other methods of treatment have been employed. In the earliest cases the protargol powder was dusted into the eye three times each day and allowed to remain fifteen minutes. This was soon changed to twice each day, but as the inflammatory reaction was marked and the patients com-

plained of severe pain, a fifty-per-cent. solution was substituted, being applied twice or thrice each day and allowed to remain in the eye three minutes. Later, a five-per-cent. solution was used and allowed to remain in the eye fifteen minutes. This last solution has proved to be the most satisfactory.

I will note only three cases of infantile ophthalmia in detail:

CASE I.—This case, of which I have incomplete notes, was that of a French baby five days old, admitted September 23d. Gonococci were found in abundance. October 3d there was great chemosis with corneal ulceration. The pure protargol was used twice each day and allowed to remain three minutes. On the fourteenth day after admission gonococci had disappeared, and on the seventeenth day the secretion was so slight that all treatment at night was discontinued. At this time the mother refused to remain longer in the hospital and we were unable to watch the case further; recovery was assured, with slight temporary ulceration of the cornea.

CASE II.—A Syrian mother brought her baby of two weeks of age to my service at the Post-Graduate Medical School suffering with purulent ophthalmia. Both eyes were attacked, pus was abundant, swelling was great, but there was no involvement of the cornea of either eye. On inquiry of an interpreter I learned that the mother had a profuse vaginal discharge, and that the ophthalmia was five-days' old, in other words, it developed on the ninth day of the life of the child. After the second visit I declined to treat the child as an ambulant patient, and both mother and child were sent by special boat to the Ophthalmic Division of the City Hospital. The mother was found to have the gonococcus of Neisser, while the secretion from the infant's eyes was rich in bacteria. Mother and child were isolated. Vigorous treatment, as already detailed, by the aid of a day and night nurse, and with the use of a solution of protargol, five per cent., so far hastened the eradication of the gonococci, and the subsidence of the inflammation that the child was discharged from treatment in 2½ weeks. In this case the protargol acted like a specific.

CASE III.—The most remarkable case is that of a baby born November 1, 1898. For several weeks previous to confinement the mother had been in the venereal ward for an obstinate gonorrhea. The child's eyes were carefully irrigated just after birth and silver nitrate, two per cent., dropped in the eyes. This was repeated on the following day. No discharge was noted until November 10th, when the left eye was attacked. The secretion at first was scanty and yellow. An examination was made at once. Pus-cells containing as high as thirty gonococci were found. The conjunctival mucous membrane was red but the inflammation was slight. Ice-pads were applied to the eye for three hours. On the following day the secretion was greatly increased and of a dirty brown color. The chemosis was very slight and the cornea bright and glistening. Ice-pads were applied constantly day and night, and the eye was irrigated with warm boric acid solution every ten minutes. Two drops of protargol solution, five per cent., were applied at 1 and 9 A.M., and 5 P.M.; and allowed to remain ten minutes. November 18th, eighth day, the discharge was so scanty and the inflammation so slight that the ice-pads were applied every fourth hour and irrigations were lengthened to intervals of fifteen minutes. The cornea remained bright and clear, and the baby would open the eye widely when the light was not too strong. By November 21st, eleven days after admission to the eye ward, the discharge had almost stopped and, as no gonoccocci had been found since November 11th (the secretion having been examined every second day) the protargol was discontinued. The eye was irrigated once each hour and the day and night nurses were discharged. On the following day the discharge reappeared and increased rapidly. The color was a dirty yellow. The gonococci were numerous, some pus-cells containing more than thirty of these organisms. On the second day after discontinuance of treatment protargol, five per cent., was used as before and the irrigations were employed every fifteen minutes. Ice-pads were applied every fourth hour. There was very little inflammation and the cornea was still bright and clear. On November 25th, after a long examination, one cell containing a few gonococci was found. The secretion was again extremely scanty. November 28th and 30th, a few gonococci were found. On the latter date it was decided to use the protargol every four hours. On December 2d, the secretion was very slight, and only one pus-cell containing gonococci could be found. There was no involvement of the cornea and vision was perfect.

In this connection a few cases of adults will be of interest:

CASE IV.—The first adult case is that of a young man (McMahon) aged nineteen years, who was admitted to the Ophthalmic Division of the City Hospital, September 21, 1898. Gonorrheal ophthalmia had appeared in his right eye two days before admission. He had concurrent gonorrhea. There was extreme chemosis and abundant discharge but no corneal involvement. Ice-pads were applied constantly day and night, and the patient strictly confined to his bed. The eye was irrigated with warm boric-acid solution every fifteen minutes. A few grains of protargol were dusted into the eye three times each day and allowed to remain fifteen minutes. This increased the chemosis and the patient complained of a severe burning pain. We then tried leaving the powder in the eye three minutes but this was also too irritating. Finally, a fifty-per-cent. solution was made, applied three times each day, and allowed to remain three minutes. On October 5th, the secretion had so far diminished that irrigations were made once in thirty minutes. Two days later the time was lengthened to once each hour. October 12th, twenty-first day, the inflammation had so far declined that the ice applica-

tions were made intermittent—one hour on and one hour off. This was soon changed to one hour on and two off, and shortly afterward to one hour on and three off. By October 25th, just five weeks after the disease began, the secretion had entirely disappeared, all treatment except an occasional drop of atropin had been stopped and the patient was up and about the ward.

In this case the secretion was examined every other day. During the early stages the gonococci were numerous and the pus abundant. The number of gonococci diminished gradually. They disappeared at the end of the third week, at which time protargol was discontinued and silver nitrate, one per cent., was substituted. Atropin was used as required. To day the eye presents leucoma, staphylomata, and pannus. The patient has perception of light but cannot count fingers.

CASE V.—Frank T., aged twenty-six years, gonorrhea concurring, an unusually virulent case. The disease appeared in the left eye September 17th, and in the right eye September 21st, the day of admission to the hospital. At this time the left cornea was deeply ulcerated and the right one hazy. Gonococci were numerous and the secretion abundant. The same treatment was instituted as in the preceding case and the strength of protargol diminished as before. On October 5th, two weeks after admission, the secretion was so much diminished that the period of irrigation was lengthened to once every thirty minutes and, two days later, to once each hour. Chemosis diminished steadily and on October 18th, intermittent ice applications were begun (one hour on and one off, one hour on and two off, and finally one hour on and three off). October 25th gonococci had disappeared. November 1st, forty days after admission and forty-four days after the appearance of the disease all secretion had disappeared, treatment was discontinued, and the patient was out of bed. With the disappearance of gonococci silver nitrate, one per cent., was substituted for the protargol. At present there is leucoma and a small staphyloma of the right eye. Leucoma and slight adhesions of left eye. Iridectomy of right eye, performed later, produced very useful vision.

CASE VI.—In the case of a boy, aged sixteen years, with concurrent gonorrhea, the gonococci were never numerous, though there was severe chemosis. His attack began September 20th. He received the same treatment as the previous patients. An ulcer of the cornea developed. September 27th ice applications were replaced by hot applications, one hour on and one hour off. On October 2d these were reduced to one hour on and three off. October 3d the applications were discontinued. From two to five irrigations were employed twice each night and then discontinued. The gonococci had steadily diminished and disappeared on the twentieth day. Result: Staphyloma and leucoma. Can count fingers at twenty-five feet.

CASE VII.—Mary R., aged forty-five, gonorrhea concurring, a syphilitic. The disease appeared in the left eye September 21st. Gonococci were numerous and chemosis was severe. A corneal ulcer rapidly developed. After one week the pure protargol was replaced by a solution of fifty per cent. and the eye was irrigated three minutes after each application. By October 8th, seventeenth day, the intervals of irrigation were lengthened to twice each hour. Five days later the application of ice-pads at night was stopped. From October 13th to 20th they were used one hour on and three off and during the day only. Protargol was not stopped until October 15th. On October 20th, just one month after the first appearance of the disease, all treatment was discontinued and all secretion had disappeared.

I am under obligations to Dr. E. E. Woolworth, House Surgeon of the City Hospital, for the details of the cases here presented; also, to Dr. Ralph Tousey, Junior Surgeon of the City Hospital, for the stained preparations of the diplococcus shown under the microscope before the Section.

GASTRIC LAVAGE AFTER GENERAL ANESTHESIA.

BY I. P. GUNBY, M.D.,
OF SHERMAN, TEXAS.

AFTER an operation requiring general anesthesia, nausea is frequently the most disagreeable symptom. No matter how thorough the preparation or how skilful the operation, vomiting will sometimes come on with reaction, and persist for days in spite of everything the nurse or physician may do. It has seemed to me that nausea may well be called the *bête noir* of anesthesia. When chloroform, as it is now manufactured, is given carefully, and the patient watched closely and continuously, I believe one may feel perfectly safe from the dangers that were formerly supposed to attend its administration. In my experience the distress and trouble commence after the patient has reacted. This nausea is more pronounced in adults than in children, and as a rule grows worse each successive time the chloroform is administered.

The cause of the nausea after general anesthesia has not been made very clear. It has been claimed that it is due to the effect of the anesthetic on the central nervous system, stimulating the vomiting center. It has seemed to me that a somewhat general idea of the cause may be gained if one considers that the entire system is thoroughly saturated with the anesthetic. Every one of the senses is paralyzed, and all the functions more or less suspended except those of circulation and respiration. As the organs begin to recover and the nervous system reasserts its control, their efforts are first directed to the expulsion of the poison that is present throughout the body. The lungs, the skin, the kidneys, the liver, and bowels all do what they can in ex-

pelling the anesthetic. The vomiting is an effort on the part of Nature to relieve the surcharged glandular and vascular systems of the drug. Chloroform can be detected in the mucus vomited for some days after its administration. Of course, some of the drug is swallowed with the saliva during its administration, but I am convinced that the stomach in this and some other conditions in which the system is profoundly poisoned takes upon itself an excretory function, separating the offending material from the circulation and expelling it from the body.

Patients find relief from the nausea after chloroform when they get rid of the chloroform, and one may hasten this relief by assisting the excretory organs. These patients should breathe the purest, freshest air that can be had, their bodies should be bathed and rubbed, the kidneys should be kept active, and the bowels moved. They nearly always find relief when the bowels move freely, but this is sometimes difficult to accomplish on account of the stomach rejecting every purgative that can be given, and, unfortunately, the laboratory department of our profession has not yet furnished us with an effective cathartic that can be administered hypodermically.

During the month of January, 1898, I gave chloroform to a woman who had been accustomed to wash her stomach out for some time on account of some digestive disturbance. While taking the chloroform, and after its administration was discontinued, she retched and vomited a great deal. When she regained consciousness she called for her stomach-tube, and proceeded to flush her stomach with warm water. It afforded her relief from the nausea immediately, and later in the day she took nourishment, and on the next day ate as heartily as usual. Her experience made quite an impression on me, and I determined to try the method thoroughly. I have found that patients experience some difficulty in swallowing the tube the first time when they are conscious, so I determined to irrigate the stomach before they fully regained consciousness. My colleague, Dr. King, and I have carried out this measure in nearly every operation we have performed on adults during the past eleven months, and it has almost uniformly succeeded in relieving our patients of nausea, or rather in preventing them from experiencing nausea. It has, indeed, made the after-treatment much simpler and easier both for our patients and for ourselves, and in some doubtful cases we have thought that their escape from nausea turned the wavering balance in their favor. On looking up our records, I find that we have employed the measure more than fifty times, and the list of operations after which it has been employed covers a considerable range. One was a case of abdominal hysterectomy, another of resection of the intestine, and there were a number of laparotomies for various causes. In all these patients there was scarcely any nausea. Occasionally there was some vomiting, but it was of short duration, and the patients experienced very little distress. They were more cheerful, and took and assimilated nourishment very much more readily than had been usual in similar cases under our observation. The nurse in charge of the Sherman Sanitarium, where most of these operations were performed, soon became an enthusiastic advocate of the procedure. She believed that it relieved her and the patients more than anything that could be done.

The method we employ is that of flushing out the stomach by means of an ordinary stomach siphon just as the chloroform is discontinued, and while the operator is applying the dressings to the wound. From one to two quarts of warm water is used, it being continued until the water returns free from bile or mucus. In order to keep the patient's teeth from closing on the tube, the use of a mouth-gag or large cork is necessary. It is best to have a large-sized stomach-tube, as the smaller ones often become choked by thick mucus. Not more than ten or twelve ounces of water should be introduced at a time, as larger quantities are apt to cause some retching. We have found that the distance from the mouth to the stomach varies considerably, and a little judgment is required to introduce the tube just far enough and not too far.

How this lavage acts in preventing nausea I cannot say. It certainly does not clear away enough chloroform to amount to much. It cleanses the stomach of the accumulated mucus, bile, and saliva, and in some way gives to it a freshness and vigor that enables it to send its contents down the intestines instead of up the esophagus. I think the simplicity of this method should commend it to all. It can be easily carried out in a few minutes without annoying the patient, for he is not conscious that it has been done unless informed of it afterward. It hastens convalescence by enabling the patient to take nourishment much sooner than it otherwise could be taken. It will decrease the dread of chloroform, and render operations generally less objectionable. I sincerely believe the time will soon come when a gag and stomach-tube will be a part of the outfit of the assistant who gives the anesthetic, and that every anesthetizer will be instructed in their use just as regularly as in the administration of the anesthetic.

Trachoma in Hungary.—Trachoma is widely spread among the 8,000,000 inhabitants of Hungary, four in 1000 being afflicted with the disease.

CLINICAL MEMORANDUM.

A NASOPHARYNGEAL POLYPUS OF ENORMOUS SIZE.[1]

BY MAX THORNER, M.D.,
OF CINCINNATI;
PROFESSOR OF CLINICAL LARYNGOLOGY AND OTOLOGY IN THE CINCINNATI COLLEGE OF MEDICINE AND SURGERY; LARYNGOLOGIST AND OTOLOGIST TO THE CINCINNATI HOSPITAL.

NASAL and nasopharyngeal polypi of more than average size are occasionally encountered, but the specimen of polypus here presented, which was taken from a patient on April 23, 1898, is of such unusually enormous size that I present it on this account.

The patient, a white man, thirty years old, was admitted to my service at the Cincinnati Hospital, his complaint being inability to breathe through his nose, fulness in the head and deafness and continuous roaring noises in the ears. This annoyance had existed for several years, and was first noticed some seven or eight years ago. He stated that he had been operated upon several times, the last time at Washington, D.C., about one year before, when a tumor had been removed piecemeal from his throat, but not very long after the operation the obstruction again made itself felt.

The patient had the characteristic expression of a mouth-breather. Hearing was very much diminished, and the voice had the characteristic nasal twang. Upon examining the throat a large polypoid mass of grayish color and glistening surface about the size of a pigeon's egg could be seen protruding below the right side of the soft palate. The soft palate itself was immovable during phonation and was undoubtedly pushed forward. Upon lifting the palate with a palate hook, which could be very easily done because the mucous membrane was apparently obtunded, it was seen that enormous white masses of irregular size filled the entire post-nasal space. The site of origin of these masses could not be made out, but it was apparent that it was somewhere on the right side of the pharynx. The left nasal fossa was free, but the right fossa was filled posteriorly with the same polypoid masses. I was under the impression that I had to deal with several polypi, and expected to remove them one after another.

On April 23d I operated upon the patient in the presence of the internes, Drs. McKee, Iglauer, and Dean, under cocain anesthesia. I introduced a cold-wire snare behind the soft palate, and pushed it up as far as possible over the polypoid masses. After some difficulty I succeeded in extracting this enormous mass of polypoid tissue, and found to my utter astonishment that I had removed the entire growth, which represented one large polypus, consisting of many large and small lobules. Some of these lobules were of the size of a small hen's egg. (The illustration does not convey an exact idea of the specimen as it was made after the latter had been in a solution of formalin for some time and had become hardened and somewhat contracted.) The tumor was attached by a slender pedicle of the diameter of a thin lead-pencil to the right lateral wall of the pharynx just in front of the orifice of the Eustachian tube, and after the operation the bleeding-point of its insertion could readily be seen with the aid of a rhinoscopic mirror. The right nasal fossa, of course, was free after the operation, as the

Exact size of nasopharyngeal polypus removed from the patient.

[1] Read at the annual meeting of the American Laryngological, Rhinological and Otological Society, at Pittsburg, 1898.

mass which had been seen in its posterior portion was but a part of the polypus.

The growth is a so-called mucous polypus, which, as we know now, is nothing but a fibroma edematosum, and, though located in the post-nasal space, must not be confounded with a nasopharyngeal fibroma, which usually takes it origin from the periosteum of the basilar portion of the occipital bone and the anterior surface of the upper cervical vertebræ. There is little doubt that this polypus originated in the posterior portion of the right nasal fossa near the choana, and that by reason of its location and weight it descended into the post-nasal space, where the conditions for its unusual development were very favorable. The hemorrhage following the operation was insignificant. The largest diameter of this tumor is 2¾ inches, its greatest thickness 1⅜ inches, and its weight 1 ounce, 5 drams.

I have been unable to find a record of a post-nasal polypus of similar size.

NOTE.—No recurrence had taken place up to December 22, 1898, eight months after the operation, when the patient presented himself again for reexamination.

SPECIAL ARTICLE.

THE MEDICAL NEWS' INVESTIGATION INTO THE CLAIMS OF CHRISTIAN SCIENCE.

BY JOHN B. HUBER, M.D.,
OF NEW YORK;
ASSISTANT TO THE CHAIR OF PRINCIPLES AND PRACTICE OF MEDICINE IN THE NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.

IN the following report to the MEDICAL NEWS on the results of an investigation of Christian Science from the viewpoint of a doctor of medicine, although a number of general observations are set down, a consideration of this cult as a philosophic system has not been attempted. I have in the main confined myself to an examination of the Christian-Scientists' method of treating the sick and of the results claimed for this method. In pursuance of this plan I have gathered the histories of some twenty people treated "in Christian Science," and these histories are detailed in this paper.

To begin with I called at the "First Church of Christ, Scientist," in Forty-eighth street, between Sixth and Seventh avenues, this city, having a card of introduction to Mrs. Stetson, the "pastor" of the church. I went in at the basement and entered a large room which was very comfortably furnished and which had an air of inviting warmth; one got the impression that esthetic effects had been attempted with much success. A gentleman took my card to Mrs. Stetson. In the meantime I observed several hundred men and women (the latter much the more numerous) chatting in groups. It seemed a well-dressed, a well-to-do, and so far as I could judge at the time, an intelligent company.

I was presently taken to a room such as would be the vestry-room in an ordinary church and here I met Mrs. Stetson. During my call of half an hour I complimented her upon the pleasing appearance of this room. Photographs, pictures, flowers, and a divan (upon which were placed silk and embroidered cushions) were artistically arranged, the carpet was very soft and everything seemed calculated to create an agreeable impression and to make one feel at ease. Mrs. Stetson, in answer to my compliment, said it was a principle in Christian Science to arrange a patient's environment so that the senses would be pleased and gratified. Cleanliness, good order, and all other wholesome conditions were a means to an end—"they helped, though in a minor way, to cure the patient."

Mrs. Stetson kindly appointed a time several days later for me to call again. In the meantime I prepared a number of questions; Mrs. Stetson preferred not to answer these questions herself but arranged to send them to the Reverend Mary Baker G. Eddy, the *Mother* of the Christian Science Church. This was done through the agency of a Mr. Metcalf. I wrote a letter to Mrs. Eddy which accompanied the questions. There were in all some twenty-eight, among which it was asked if the treatment of the sick is a part of Christian Science; upon what principle the Christian Scientists' method of teaching the sick is founded; how the Christian Scientist defines health; how the Christian Scientist defines disease; if, on the patient presenting himself, the causes of his disease are inquired into; if symptoms are investigated; if post-mortem examinations are made; if diagnoses are made; if material substances (drugs) are administered to the patient; how a patient is treated; what is done in infectious diseases; if Christian Science can, without the administration of drugs, cure patients in whom the structure of the organs is diseased; if surgical injuries, such as fractures of bones, are treated "in Christian Science;" if animals, when they become sick, can be cured by Christian Science, etc.

I received no reply from Mrs. Eddy, but Mrs. Stetson informed me the matter had been referred to Mrs. Eddy's counsel, Septimus J. Hanna, Esq., of Boston, Mass. Judge Hanna sent Mrs. Stetson a letter on the subject, which Mrs. Stetson kindly turned over to me with permission to use it as I should see fit. A copy of this letter follows:

"Editorial Office of THE CHRISTIAN SCIENCE JOURNAL,
"95 Falmouth St.
"BOSTON, MASS., November 18, 1898.

"MRS. A. E. STETSON,
"New York City.

"DEAR SISTER:—Mr. Metcalf handed me the questions submitted by Dr. Huber. I have also received and carefully read your letters. As I think Mr. Metcalf has informed you this matter was referred to me from Concord. I have been so very busy that I have not had time to give this matter the thorough attention it needs until now.

"I have carefully read and considered the entire paper. My conclusion is that it will be wholly impractical, indeed, I may say, impossible to answer these questions in such a manner as to make an entire paper fit for publication in a medical journal, or in any other magazine or periodical. The questions submitted touch the entire subject of Christian Science both in its theology and ther-

apeutics. These questions can be answered only in one way, so that they can be understood; and that is by just such study of the Bible and "Science and Health, with Key to the Scriptures" as the earnest, sincere Christian Scientists are giving them every day of their lives and have been for years. When we think of the helps provided by our leader, the Rev. Mary Baker Eddy, for her own students in arriving at a correct interpretation and putting into practice the teachings of these text-books, such as the publications established by her, the Bible lessons made up of selections from the Bible, and our text-book constituting the sermons for our study in all the Christian Science churches, the many auxiliaries she has published and is publishing in further illuclucidation (*sic*) of the text-books; when we stop to consider that even those of her students who may be considered the most advanced are yet mere infants in the understanding and ability to demonstrate the truth contained in these text-books, can we not easily see, and will not your friend, the doctor, at a glance, see the utter futility of attempting to answer his questions so as to make the answers intelligible to the medical profession and their readers? I admire greatly the kindly spirit manifested by the doctor and those for whom he is acting and the entire fairness, from their standpoint, of the questions submitted, but this does not relieve the difficulty of the situation. I therefore return the doctor's questions with many thanks in behalf of our leader and the cause for the impartial spirit manifested.

"Yours in truth,

"S. J. HANNA."

I wish, in passing, to state that I have put the question "Do you isolate a patient suffering from an infectious disease?" many times to many Christian Scientists. I consider this question simplicity itself and I think any sane person possessed of merely rudimentary honesty should be able at once to answer it intelligently and satisfactorily. But so profound is this "Science" and so spiritualized are its devotees that I have not been able to obtain from any one of these people a straightforward answer. No doubt Judge Hanna, being a lawyer, could, if he chose, tell the reason why he who asks such a question as this would have to spend months or years in Nirvana-like abstraction before he would be able to appreciate an answer to it.

He who would be a good Christian Scientist must have in his possession the Bible and the book, entitled "Science and Health, with Key to the Scriptures." If he would be a good Christian Scientist "Science and Health" must be his *vade mecum*. As he reads this book he is likely to be compelled to stop several times at every page and meditate upon what he has read. At the end of his meditation the passage will probably be no clearer to him than when he began to think. Mrs. Eddy has therefore provided other works to explain the statements made in "Science and Health." There are at least twelve such works, or collections of works, comprising books, pamphlets, and sermons, and ranging in price from 20 cents for a sermon to $6 for a book. Everything of a copyrightable nature which I have seen, including Mrs. Eddy's photograph, has been copyrighted. In some instances the truth can be had by the job-lot and at correspondingly reduced rates, as one copy of a pamphlet for 50 cents and twelve copies for $4.50. Many of these works have passed through a number of editions. I took a copy of "Science and Health" to the rooms of the American Bible Society in Astor Place, New York City. This society is engaged in the endeavor to disseminate truth solely for truth's sake. This one book ("Science and Health, with Key to the Scriptures") costs $3 over a book-store counter. It has now passed through at least 153 editions. I showed this book to the gentleman in charge at the Bible Society. He produced a Bible similar to this book as regards type, paper, binding, etc., the essential difference in make-up between the two being that there are 651 pages in "Science and Health" and 1285 pages in the Bible. It costs less than 40 cents to put this Bible on the book-store shelf; and the Bible Society sells it for 50 cents. This society gives a discount of ten per cent. from its list prices to auxiliary societies and to dealers in books.

I am told that Mrs. Eddy had to borrow the money with which to publish the first edition of this book, and that she is now a millionaire. On the most conservative estimate this statement seems altogether credible. Mrs. Eddy, at all events, must have found extremely remunerative the business of elucidating (?) the truths set forth by the poor Nazarene. Besides Mrs. Eddy there are those among her followers who have produced works on Christian Science; these works (which are not presented to truth seekers) are not to be studied by the faithful unless they bear the stamp of Mrs. Eddy's approval and they are not used in the various classes unless by her permission. The mercenary motives underlying this movement will be further commented upon in the course of this paper.

I have been present at several "experience meetings" in the Christian Science churches. There is an organ prelude, then a reading from the Bible, after which comes the reading of an extract from "Science and Health." A discourse follows, several hymns are sung, and finally a number of people rise from their seats and relate how they have been treated, or, in their opinion cured "in Christian Science." There is no benediction. In the audience women were greatly in the majority; I counted in one gallery twenty-nine people of whom twenty-five were women. These meetings were held in the evening. There are said to be about 3000 Christian Scientists in and about New York City. There are seven churches in the Greater New York, four of which are in the Borough of Manhattan. These four are located as follows: (1) At 143 West Forty-eighth street; (2) in West Eighty-Second street, between the Boulevard and West End avenue; (3) 80 West One Hundred and Twenty-sixth street, and (4) now situated on the corner of Twenty-ninth street and Madison avenue, for which a new building is being erected on the corner of Eighty-sixth street and Central Park West. The "pastors," or "first readers" as they are also called, of these four churches are all women, at least one of whom enters the pulpit gowned and bediamonded as for a social function. These churches are, then, in the neighborhood of the well-to-do; there

are, so far as I know, no mission churches in the poorer parts of the city, and it does not seem to be the endeavor of those at the head of the movement to carry the blessings of "Christian Science" among the poor. Indeed it is a tenet in Christian Science that one has no business to be poor. All the Christian Scientists I have met and seen appear to be above actual want and some of them are evidently very wealthy.

I find among these people very few of the very young men and women; this I would explain on the assumption that youth is likely to be normal in its mentality. On the other hand I have seen many in middle and in advanced life who seem to me to have in their earlier years found it difficult to conform their minds and bodies to the universal scheme; who have probably found it irksome to live in accordance with Nature's laws; who have as a result, been unhappy and dissatisfied with life; who have taken up, one after another, faith-cure, theosophy, spiritualism, etc., and are now trying Christian Science as the latest of these fads, to cast it aside in its turn as soon as they find it as great a delusion as its predecessors. These people are no doubt especially numerous in these times of unsettled problems and of unphysiologic living. I have, indeed, met a number of people who *have been* Christian Scientists, and who rather pathetically state that they have found this movement as illusory as any other of its kind.

Every Christian Scientist, every little child even, can be a "healer" in Christian Science. The treatment is carried on by means of thinking, speaking, or writing. No material substances are prescribed (so I am told) and no topical applications of any sort are employed, indeed, the administration of drugs would render ineffectual the healer's efforts. The treatment is alleged to be purely mental. Some, but not all healers, take obstetrical cases; however, it seems generally preferable to have a physician called in to deliver the child and the placenta, but he is not permitted to do any more than this. While the physician is thus engaged the healer stands by the patient's bedside and thinks. The healer charges fees for his services the same as the physician does. It costs to be healed in Christian Science!

The healer need not know what the patient complains of, but the patient may, if he wishes, "put in a claim," that is, he may tell what is the matter with him. To the healer, however, it makes no difference whether the patient tells or does not tell what he suffers. The latter, moreover, does not need to be with the patient (*vide* "Science and Health"). This is an undoubted convenience from the healer's point of view, all the more for the reason that the Christian Scientist charges a fee for each treatment whether he be with the patient or not. In the middle of the night a friend of the patient may go, or may telephone for that matter, to the healer's house and inform him that the patient is ill. The healer may then, while lying on his back in his own bed, treat the patient "absently." The healer may treat absently by letter no matter at what distance. Furthermore, the healer may, without knowing it, cure in the patient a malady other than the one from which he is given to understand the patient is suffering. For example, a female Christian Scientist living in this city treated "absently" a young woman living in the northern part of New York State for irregular menses. This disorder was healed. Then the delighted young woman informed the healer by letter that she had not mentioned the fact that she had been deaf; but she could now hear, thanks to the treatment she had received from her distant Christian Science healer.

Some patients are cured in one treatment, others require a number of treatments; in some cases the patients are a long time, months or years, as long, in fact, as they remain credulous, under treatment before they are cured or discouraged into seeking other methods. The more powerful healers attempt to dissipate tumors, cancers, and various surgical diseases. Mrs. Eddy can cure anything; for instance, she has healed in one sitting a cancer which had eaten down to the jugular vein; she does not trouble herself to supply for investigation the names, addresses, etc., of such subjects. But who could expect the "Mother" of this "church" to descend to such petty details! However, among the rank and file there seems to be some difficulty about the healing of surgical diseases; in fact it is acknowledged that at present the treatment of such diseases by the ordinary healer is rather unsatisfactory, although it has been reported (among other interesting statements) that a short leg has been made long by means of Christian-Science treatment.

Here an observation may, very humbly of course, be ventured. The Christian Scientist holds that "all is mind; there is no matter." Now the benighted outsider would arrive at what he would consider the logical conclusion that if this is so it should be as easy to dispose of a fractured skull as of an attack of hysteria and that (it being unnecessary according to the Christian-Science dictum to take into consideration the varying densities of tissues) it should take no longer to cure a cancer than to cure a bilious headache. But to this the Christian Scientist would say that Christian Science is still very young and that its adherents have not yet been sufficiently saturated with "the truth" to be able to overcome the greater difficulties. In the course of time, however, the more stubborn diseases will succumb—nay, the time will come when the dead will be taken by the hand and raised from out their coffins (again *vide* "Science and Health").

Christian Science can also make sick animals well; in these cases the cure is achieved by thinking or talking, and it is alleged that no material remedies are used.

I am informed that at the end of a course of study in Christian Science the student is given the following formula which he is to use in treating disease. For instance, the patient "Kate" has a cough; she is thus mentally addressed: "Kate, you are not sick and you know it. There is no matter, therefore matter cannot pain. You are a child of God, who gave you the power to govern your present condition. But you are not aware of it. Therefore I, who manifest God, I, who reflect the Divine idea, I, who am a follower of Christ, who said "Verily, verily I say unto you, the same things which you see me do now, those will do that believe in me, and even more." I, who do not *believe* but *know* that nothing can stand up before

infinite mind, I say that cough which troubles you must go. Get thee behind me and dissolve thyself into nothingness whence thou comest, for thou art nothing but the work of mortal mind, which itself is only the upper stratum of matter which exists not." I am told also that the healer may, if he wishes, speak this formula while treating the patient.

(To be continued.)

THERAPEUTIC NOTES.

Nosophen and Nosophen Gauze.—HORACE TRACEY HANKS (*American Gynecological and Obstetrical Journal*, December, 1898) renews his favorable opinion regarding this medicinal substance in gynecological work. After an experience of nearly four years with nosophen he believes that it has virtues equal to those of iodoform. It has the additional advantage of being free from odor. He commends it for its efficiency in preventing excessive and rapid suppuration in all abrasions and on all raw surfaces after curettage, when this procedure is applied for endometritis or for removing the débris of an abortion. The nosophen gauze is also efficient as a dressing for abdominal wounds.

Colloidal Silver and Blood Poisoning.—WERLER (*Deut. med. Wochenschr.*, October 6, 1898) has convinced himself that Credé's last soluble silver salt, which bears the name of colloid silver, is a specific for sepsis. It is administered not in solution by the mouth, but in the form of inunctions, the salve employed containing 15 per cent. of the soluble silver, about 15 grains of such an ointment being rubbed into the skin of the chest or back every night. Improvement in the general condition, in the cases of surgical sepsis from minor wounds which Werler reports, occurred after only one inunction had been made. In order to effect a cure, however, it is necessary to repeat the treatment from five to twenty times according to the nature of the case, those conditions which are chronic requiring a longer course of treatment. Locally a wet dressing of silver citrate, 1 to 4000, was employed. Unfortunately in all of the cases reported by this observer, the focus of infection had found its way to the surface of the body at about the time that treatment was begun, so that it is open to question whether the subsidence of general symptoms was not dependent upon this fact. In the treatment of chronic furunculosis, the use of the silver salve was eminently satisfactory.

Urotropin in the Treatment of Cystitis. — KELLY (*Therapist*, October 15, 1898) realizing that cystitis is due to the invasion of the bladder by micro-organisms, says that the first indication for treatment is to render the urine antiseptic. For this purpose he has tried with a certain amount of success, salol, ammonium benzoate, guaiacol, resorcin, benzo-naphthol, sodium salicylate, creasote and other preparations. They are all helpful in making the urine antiseptic, but no one of them has given him the complete satisfaction which he has had from the use of urotropin, a non-toxic and non-irritating derivative of formic aldehyd. It is formed by the action of four molecules of ammonia on six molecules of formaldehyd, and was first introduced to the profession by Nicolair in 1895, who asserted that it possessed the power of dissolving uric-acid concretions and also that taken *per ora*, it prevented the development of bacteria in the urine. In cases of phosphaturia and cystitis its action is almost a specific one. It appears in the urine as early as fifteen minutes after its administration, and its presence can be recognized twelve hours later after a dose of 7½ grains. It is soluble in 1.2 parts of water at 68° F., and the reaction of its solution is faintly alkaline.

If the condition of the patient is a very bad one large dose of the drug should be given, as much as 20 grains twice a day; and if the urine is strongly alkaline, a little dilute mineral acid should also be given until the reaction is improved. Kelly gave these remedies to a man aged thirty-five years who had suffered for a long time with cystitis. Nine days from the beginning of treatment the urine became clear and slightly acid, and in fourteen days it was free from pus. This was the first time in fifteen years that he had passed clear urine. The dose of the urotropin was gradually diminished, and discontinued altogether in a couple of months. There was no return of the trouble.

Epistaxis Cured by Poultices.—ROCHE (*Brit. Med. Jour.*, December 10, 1898) has used with success for stopping a nose-bleed a very hot poultice on the back of the neck. This simple treatment has never failed him, and has succeeded in a number of instances when other remedies, such as compression, ice, and astringents, had failed to stop the bleeding.

Foreign Body in the Trachea Removed by Intubation.—SEVESTRE (*Zeit. f. prak. Aerzte*, November 28, 1898) passed a laryngeal tube into the throat of a five-year old girl who had swallowed a glass bead about a third of an inch long and half as broad, and who suffered from attacks of asphyxia. In case the intubation had failed, it was to have been followed by a tracheotomy. Some minutes after the tube was in place, the foreign body was coughed out. It had lain in the trachea for more than six weeks.

Suture of Wounds in Veins.—SCHULTES (*Deut. Zeit. f. Chir.*, vol. 49, p. 624) says that the suture of a wound in the side of a large vein has so many advantages over the other methods of treatment of this accident, such as compression, lateral ligature, or the application of a clamp, that it is the only permissible procedure. Compression almost certainly produces thrombosis, a lateral ligature is likely to slip off, and clamping by no means insures the union of the edges of the wound in the vein. All of these disadvantages are avoided by the suture of the rent. Of the twenty-six reported cases of patients treated in this way, twenty-three recovered without complication, and death in the other three instances was in no way due to the venous suture.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

J. RIDDLE GOFFE, Ph.M., M.D., Editor,

AN INVESTIGATION OF CHRISTIAN SCIENCE.

THE somewhat sudden appearance in this country of the cult known as Christian Scientists and the aggressive attitude shown by its disciples in the practice of "healing the sick" for hire has naturally aroused the opposition of the medical profession. This opposition, however, has been stimulated thus far by the natural instinct of saving the innocent and credulous from what ostensibly appeared to be the workings of a religious mania. Nothing, however, was definitely known of the foundation of this belief or the history of its organization. In order that the medical profession might have placed in its hands definite and complete knowledge of the basis upon which the claims of this sect are founded, the MEDICAL NEWS deemed it wise to institute a careful investigation. Dr. John B. Huber of New York kindly undertook the task and, after a careful and conscientious study of the subject, involving much time and arduous labor during the past three months, now presents to the readers of the MEDICAL NEWS the results of his searching inquiries.

No effort has been made to discuss this cult as a psychologic system. The investigation has been confined to an examination of the Christian-Scientists' method of treating the sick and of the results claimed and obtained in its application. In pursuance of this plan, twenty cases of people treated "in Christian Science" have been personally investigated and all the facts conscientiously recorded. So far as we know, this is the first attempt that has been made to investigate and follow carefully to their conclusion a series of cases designated by the Christian Scientists themselves as illustrative of the success of their work. The report of Dr. Huber sets forth the facts as he found them in each case. It gives an interesting and instructive picture of the disingenuousness of the leaders of this doctrine and reveals the emptiness of their pretensions as applied to the healing of the sick.

In an address delivered recently at a Christian-Science meeting in Brooklyn the statement was made that there are seven Christian Scientist churches in Greater New York and thirteen in the immediate vicinity, thirty-eight churches and congregations in the State of New York, and about thirty thousand adherents of the faith in the State. It was also claimed that there are one million Christian Scientists in this country. If this is true, it is time that a little sunlight of well-founded knowledge should be shed upon the mercenary motives and religious hypocrisy of the originators of the sect, their criminal responsibility for many deaths, and the utter emptiness of their claims when practically applied.

MEDICAL ADVERTISING FRAUDS.

IN one of the large department stores in a neighboring city, where one may find "all things needful from the cradle to the grave" (see advertisement), the employee who fits glasses in the most approved style and without charge was recently seen attracting custom to the store by examining the eyes of a presumable patient, but probably a fellow-clerk, in one of the large windows. His maneuvers soon drew a crowd, and doubtless many went away with a fixed purpose of soon submitting to the scientific investigation of the operation. The fact that he was using a head mirror with the light behind him instead of in front of him and that it is not easy to detect an error of refraction with a four-inch concave mirror did not inspire the passerby so forcibly as did the array of instruments displayed, including an ophthalmometer and compressed-air apparatus, and the

assumed look of intelligence upon the operator's face.

We are all familiar with the old clergyman and retired missionary who has a sure cure for consumption and who, in his gratitude for restoration to health, is anxious to send free the formula which has cured him. As well do we know that when this formula comes it will contain one or more ingredients which cannot be supplied by any druggist—and even the department store is unable to fill the order. When we write to this generous clergyman he informs us that the drug in question is very rare. It should be kept, however, by all first-class druggists but, if we have difficulty in obtaining it, for a few dollars he will send a supply of the medicine, and in the meantime he will find out why our druggists are so lax in this respect.

And now comes a supposedly reputable firm of manufacturing pharmacists which is trying to bunco the profession in a similar manner. A circular is sent broadcast extolling the virtues of a drug which cures cataract by stimulation of the absorbents and a dissolution of the opaque matter in the crystalline lens or its capsule. Appended to the report are a number of glowing testimonials, and there follows this note: "We will be pleased to furnish the address of any of the physicians whose testimony is given in the foregoing on request." Somewhat interested in this matter a request was made for the addresses of the physicians and it elicited the following circular letter:

We are in receipt of your favor of recent date, and pleased to know you are interested in ——. While we could refer you to a number of physicians who have used this remedy successfully, they have recently had so many letters, on account of our publishing their names in our circulars, you would probably not receive a reply for some time as, of course, they are very busy and could not answer all of them. Dr. —— of —— avenue, this city, has made a special study of —— in the treatment of cataract, and if you would address him, he could, no doubt, give you some information. We trust you will give the remedy a trial as, from the reports we have received from physicians who have used it, it certainly has done much good, and is worthy of a trial.

The four testimonials appended and presumably from medical men are from these sources, according to Polk (1898): The first is a resident of a parish in Louisiana with a population of 30. The next two are not found at all, but the fourth name appears twice. The first is a professor of gynecology in a Western city, the second a specialist in female troubles and private diseases. Evidently if cataracts are to be intelligently treated by such men we will have to revise our etiology of the disease. The one man whose name is given is a graduate of a homeopathic institution of but a few years' standing, and is in the employ of the concern.

It is an insult to the profession to ask its members to essay a trial of any therapeutic measure upon such testimony, and is another bit of evidence that the whole system of testimonials and testimonial-giving is clap-trap and a fraud.

PROFESSOR BEHRING AND HIS REWARDS IN GERMANY.

IT is announced that Professor Behring and Dr. Ruppel of the University of Marburg have applied for a German patent for a serum to be used in the treatment of tuberculosis. According to the wording of the application, what the inventors claim to have discovered is "a method of preparing from tubercle bacilli or from cultures containing tubercle bacilli, a highly toxic substance capable of producing immunity to the effects of the tubercle bacilli."

When his application for an American patent for diphtheria serum caused such vigorous protest on the part of the medical press all over the world, Behring said that the rewards of a medical investigator were so small in Germany if he followed the beaten paths of medical custom in giving his discoveries to the world, that he had made up his mind to break with precedent in the matter and reap, if possible, the commercial advantages of exclusive rights in his remedy. In the light of what our foreign correspondent wrote after a visit to Marburg (MEDICAL NEWS, May 4, 1898), it is easy to see how flimsy is Behring's excuse for entering the commercial field under the banner of the Höchst Farbwerke.

Shortly after the importance of his discovery became assured, Behring received the call to the Chair of Hygiene at Marburg. The salary is not princely; no German university Professor's is. Owing to peculiar conditions, however, and to the fact that Prussia confiscated the revenues of the Duchy in 1866, and that it has been the constant effort of the Prussian government to keep Marburg on a higher

plane than the rival and neighboring University of Giessen in the Duchy of Hesse, Marburg has been especially favored among the Prussian universities, and has always had an ample revenue. A magnificent set of laboratories is located here, of which Behring's is not the most poorly equipped. In his position he has had the privilege of an assistant, to whom he might delegate practically all the drudgery of teaching, reserving his own time for the more important work of investigation.

Most scientific investigators would be apt to consider this ideal. Marburg is beautifully situated in the valley of the Lahn. It rivals in the picturesqueness of its situation though not, perhaps in historic associations, the far-famed Heidelberg, or Bonn, or Jena. All this surely was no unsubstantial reward for Behring's part in the serum discovery. Then he became the diphtheria-antitoxin expert for the Höchst manufactory, a huge concern which employs some 9000 men, mostly in the manufacture of dyes from coal-tar. In connection with this they manufacture coal-tar derivative products for use in medicine. It is this concern which owned the antipyrin patent, in which there has been millions, and it is its success with this that has tempted it into the antitoxin field. Shortly after Behring's connection with the Höchst concern began he erected a laboratory on the heights overlooking Marburg. It is most picturesquely situated above the town, and is itself an imposing granite building of striking beauty architecturally. It is here that of late most of his investigations have been carried on, though his apparatus for evaporation of tubercle-bacilli cultures without the destruction of the bacilli, by means of vacuum chambers, is at the university laboratory down in the town.

To pretend that a man situated like this *needs* to violate all the principles which so far the profession has kept sacred is carrying the plea to too great length. It is plain that it is the money-making side of the question alone that has influenced the medical scientist to depart from a consecrated usage to ask for exclusive rights in the sale of his remedies. Every medical man is bound, then, to oppose as far as he is able, the grasping spirit it implies. Not alone the present issue is at stake but the profession must give a lesson which will impress others who may become inoculated with the commercialism so rife at present. It is quite within the range of possibility that a thoroughgoing inflammatory reaction in the body medical now would produce enough mercenary antitoxin to make its members immune against attacks from this insinuating microbe for some time to come.

THE SUCCESS OF GALL-STONE SURGERY.

THE fact that any one surgeon has performed one-hundred operations for gall-stones is in itself quite worthy of mention. But a German surgeon named Kehr has the remarkable record of 360 laparotomies of this character, 151 of them being performed in the last two years. Kehr lives on the north side of the Hartz Mountains, in Halberstadt, a town of less than 40,000 inhabitants, which up to the present time has been familiar to American doctors chiefly on account of its curiously carved wooden houses, some of which date back to the Fourteenth Century. It is not much more than one hundred miles from Berlin, and the whispers of jealous colleagues must have reached the ear of Hans Kehr, for he feels obliged to explain why he should be called upon to operate upon patients suffering from gall-stones at the rate of six a month, while his more celebrated professional brethren in the larger cities have to content their souls with a dozen cases a year. The reason given is that the physicians in the region about his town have become very proficient in making the diagnosis of gall-stones, and knowing the good results which follow an operation done in the early stages of this trouble, they lose no time in persuading their patients to go to Kehr. The difference between German methods and our own is strikingly illustrated by the fact that one physician who has been especially successful in getting his patients to submit to operation, backs up his advice by the withdrawal of morphin in case the patient does not agree with him. This measure, he says, is well-calculated to help the patient decide upon an operation.

However, the results obtained by operation are so good that it seems allowable to resort to almost any measures to induce the patient to agree to the removal of his gall-stones; and the low mortality and permanency of cure are of course the chief reasons why Kehr has been able to go on performing these operations at an ever-increasing rate. He numbers

among his patients people from all Europe, as well as from the various German provinces.

The mortality in these 360 cases, irrespective of the condition of the patient at the time of the operation, is 11.7 per cent. If deaths from other causes, such as carcinoma, suppurative cholangitis already advanced at the time of operation, and complicating operations, such as gastro enterostomy, are omitted, there remains only twelve deaths in 327 laparotomies, or 3.8 per cent. mortality. That is, indeed, a low figure for an operation which is at best a difficult one, and which often requires three or four hours for its completion. But the results in some special classes of cases are even better. Thus cystostomy was performed upon 180 patients who had stone in the cystic duct or in the bladder. Only three of these patients died, in all of whom it was found impossible to suture the gall-bladder to the parietal peritoneum.

Kehr believes in making the details of operation as simple as possible. He has only one assistant and one nurse. No gloves are worn, but one-half hour is spent in sterilizing the hands, and occasionally during the operation the hands are washed with bichlorid and normal salt solutions.

Kehr's article is full of suggestions, and is heartily recommended to every surgeon. It is No. 225 in *Volkmann's klinische Vortraege*. He emphasises the importance of determining before operation not only the presence of a gall-stone, but its exact situation. Thus, if there are impacted stones in the common duct, it would be the worst treatment in the world to open the gall-bladder and so destroy the pressure of bile which, if left to itself, might drive the gall-stones forward into the intestine. He never operates, therefore, on a patient in an acute attack of closure of the common duct. He never operates upon carcinoma of the common duct or pancreas; at most, nothing more than an exploratory laparotomy is done in order to make sure of the diagnosis. Patients over sixty years of age who have jaundice and slight colic may be considered in most cases to have carcinoma.

Slight distention of the gall-bladder after some operations causes a spasm of its walls and pain. This occurs when the patient is fasting. It is of benefit to give such a patient a meal even in the middle of the night, as the presence of the food causes the bile to flow into the intestine instead of into the bladder. The "ideal" operation, that is, suture of the gall-bladder and its return to the peritoneal cavity, is risky, and its originator, Czerny has abandoned it. The drainage of the bladder for a few days is a help toward recovery and not a drawback.

Kehr takes a bright view of the future of gall-stone surgery, and it is not to be wondered at that he does. His figures are as good as, or better than, those obtained in the operative treatment of appendicitis. Autopsies show that great numbers of people have gall-stones without having suspected it. The proportion is at least one in thirty, and some counts make it as much as one in ten. Undoubtedly, most of these persons have at some time suffered from symptoms, the cause of which was not recognized by them or their medical attendants. With the popularization of this subject, and the finer differentiation of abdominal pains by the profession and laity alike, it is not unreasonable to suppose that ten years hence cholecystostomy and choledochotomy may be as frequently performed as appendectomy is to-day.

ECHOES AND NEWS.

Dr. Quinlan's Appointment.—Dr. Francis J. Quinlan of this city has been appointed Laryngologist and Rhinologist to Charity (City) Hospital, Blackwell's Island, by order of the Commissioner of Charity.

Psittacosis.—This infectious pneumonia spread by parrots has broken out again in a number of Italian towns. Some years ago it prevailed quite extensively, but decrees of municipal authorities forbidding the keeping of parrots in private houses put an end to the epidemic.

Associated Physicians of Long Island.—The regular annual meeting of this society will be held Saturday, January 21st, at the Union League Club, Brooklyn. The scientific session is scheduled for three o'clock in the afternoon, and in the evening dinner will be served at seven.

Health in Havana Camps.—Up to this writing there are three cases of suspected smallpox in the 161st Indiana Regiment. The sick are carefully isolated, and the entire regiment remain in quarantine inside the regimental camp limits. There are 119 men in the general hospital.

Revolt against Contract Medical Service.—The physicians of Oneida, N. Y., have banded together to compel the town to pay regular rates for professional visits to the

town paupers. Every doctor in town signed a paper agreeing not to bid as heretofore for the contract to care for the sick paupers, and an advertisement asking for bids has met with no response. This action is one of the symptoms of a growing revolt among the doctors up the State against contract medical service either for municipalities or for benefit societies.

Another Dispensary Bill.—It is possible that at last the abuse of medical charities in this State is to be controlled if not corrected. Although the Sullivan dispensary bill was defeated at Albany last winter, the necessity for reform was admitted on all sides. A bill has been agreed upon for introduction into the Legislature by representatives of the three State medical societies and the dispensaries, which, if it becomes a law, will in great measure correct the evils now existing. The dispensary committee are T. L. Frothingham, Esq., Dr. D. B. St. John Roosa, and J. G. Cannon, Esq.

Dangers of Tuberculosis.—The report of the special committee of the New York State Senate to investigate the spread of tuberculosis, the establishment of better sanitary conditions for consumptives and the protection of the public has been presented. It finds that consumption is contagious, and recommends that the State establish a hospital or hospitals for the treatment of cases of tuberculosis, the same to be located somewhere in the forest preserve in the Adirondack Mountains, the site to be selected by the trustees approved by the Forest Preserve Board. An accompanying bill provides for an appropriation of $200,000, the appointment of a commission to locate a site (the Governor to appoint), and the appointment of examining physicians, two in number, in each of the cities of New York, Buffalo, and Syracuse to examine patients and commit them by certificate. Patients able to pay, or having relatives able, must do so. A resolution was also offered that 4000 copies of the report be printed for distribution.

Dr. Charles W. McManus.—The Medical Board of the Willard Parker and Riverside Hospitals, having learned with profound regret of the death on January 5, 1899, of Dr. Charles W. McManus, late Interne Physician to the Hospitals, the following preamble and resolutions were unanimously adopted:

WHEREAS, It has pleased the Almighty to remove by death Dr. Charles W. McManus, Interne Physician to these hospitals, and

WHEREAS, Dr. McManus has made for himself in our hospitals an enviable record for conscientious and painstaking work and unremitting zeal in the performance of his duties, and has gained the esteem and affection of his colleagues by his admirable qualities, therefore, be it

Resolved, That this Board deeply regrets the cutting short of so promising a career at the very beginning of professional life; and be it

Resolved, That we offer to the father of Dr. McManus our deep sympathy in the terrible loss he has sustained in the death of this his only son; furthermore, be it

Resolved, That a copy of these resolutions be transmitted to the Board of Health, the father of the deceased, the medical journals, and spread in full upon the minutes of this meeting.

DR. JOHN W. BRANNAN, President.
DR. H. W. BERG, Secretary.

The State Charities of New York.—The State Board of Charities presented its annual report for the year 1898 to the Legislature this week. It states that the inmates and beneficiaries of State and other institutions within the Board's jurisdiction aggregate more than 2,500,000, and the expense of maintenance reaches nearly $22,000,000. Referring to the Dispensary Bill of last year which passed the Senate but was not reported from committee in the Assembly, the report declares: "The Board reiterates its belief that legislation is required to prevent the abuse of medical charities, now so prevalent in New York City, and also the overgrowth of such charities, and hopes that a statute which will be satisfactory to all who are desirous of rectifying such abuses may be enacted." The report of the Special Senate Commission on the spread of tuberculosis was also made and accompanying it was a report upon the spread of tuberculosis in New York City, written by Arthur R. Guerard of New York. Dr. Guerard made a special investigation of the conditions in the Fourth and Sixth Wards. In the Fourth Ward, with a population of 18,323, there are 663 dwellings and an average of 27.6 persons to each house. In 248 out of the 663 dwellings tuberculosis was found, there being in three years 541 cases. The doctor says: "Such houses would seem to be permanently infected and should be thoroughly renovated from top to bottom, or better, condemned and torn down." It must be borne in mind that this report is based upon investigations during 1896. The drastic sanitary measures put in force by the New York Board of Health during and since that year have reduced these percentages somewhat.

Medical Society of the State of New York.—The ninety-third annual meeting of this Society will be held January 31 and February 1 and 2, 1899, in the City Hall, Albany, commencing at 9.15 A.M. on the 31st, and ending at 1 P.M. on the 2d. Preliminary program: Tuesday Morning Session. President's inaugural address; reports of officers and committees; executive business. I. "Fracture of the Cervical Vertebræ, with Specimen," Chauncy P. Biggs, Ithaca. II. "An Unusual Injury to the Kidney, with Specimen," W. D. Garlock, Little Falls. III. "Formaldehyd Disinfection," W. H. Park, New York. IV. "The Close Relation between the Nasal and the Cranial Cavities, and between Nasal and Cranial Disease," Wm. C. Krauss, Buffalo. V. "The Importance of Early Examination and Treatment of Catarrhal Mouth-Breathing in the Public Schools," Clarence C. Rice, New York. VI. SPECIAL ARTICLES.

THE PRESENT STATUS OF OPINION UPON THE USE OF QUININ IN MALARIA— A REPLY TO DR. HARE.

IN the MEDICAL NEWS for January 7, 1899, we published a letter from Dr. Deffenbaugh of St. Joseph, Mo., criticizing a special article under the above title in the NEWS for December 17, 1898. He substantially agrees with the views put forth in our article but thinks that as certain conclusions therein stated are still in doubt they should not be expressed so dogmatically. In extenuation of what we are ready to admit is a dogmatic declaration on our part, *viz.:* that quinin should be used in every case of acute malarial manifestation, no matter what its type or what complication may be present, albuminuria, nephritis, hematuria, or hemoglobinuria, provided such complication is malarial in origin, the following consideration is submitted. It is a condition not a theory that the general practitioner faces in treating a case of malaria accompanied by such complications. Recent discussion and ill-advised editorial comment had made, we felt sure, many a practitioner hitherto confident in the efficacy of quinin, skeptical about its use in cases in which these complications occurred. For him we looked up the authorities on the subject and having quoted Osler and Laveran, Bacelli, and the chief officer of the Royal Niger (Central Africa) Company, we justifiably, as it seems to us, laid down the practical general rule: In malaria always use quinin no matter what the condition. It is clear from the context that we did not have reference to chronic malaria and to mention idiosyncrasies to quinin seemed unnecessary. We were not writing a treatise but drawing a practical conclusion supported by the world's best authorities in malaria for the guidance here and now of the busy practitioner.

In the *Medical Record* for January 7, 1899, Dr. H. A. Hare criticizes "in friendly spirit" our position as to the use of quinin. May we then in the same attitude of friendliness be allowed to reply. With all due respect to Dr. Hare as an authoritative teacher of therapeutics we shall in the interest of truth endeavor to point out the fallibility of his argument and his position on this question as well as substantiate by confirmation from the best authorities the correctness of our own.

Dr. Hare thinks that articles such as ours "will lead the practitioner to prescribe quinin without studying his cases thoroughly and when the condition is really not malaria at all." May we say that our article was on "the use of quinin in malaria," not in other diseases falsely diagnosed as malaria. Dr. Hare says in closing his article that quinin must be "mixed with brains" to get good results. That is all very true, but the poor fellow who begins by missing the diagnosis will probably not have enough of the second ingredient mentioned to be able to spare any of it for the treatment of his patients. Special articles are not written for him and should not be criticized from that standpoint.

Dr. Hare quotes us as saying that "the voices of our Southern medical men, of the medical men of India and of Brazil and Italy are as a unit in favor of the universal use of quinin." This is a misquotation and a serious one. What we said was that they are "a unit against Koch." The statement of Koch that they are especially united against it is explicitly set forth in the preceding paragraph. It is that quinin is given too freely in the tropics and that so-called malarial hemoglobinuria is practically *always caused* by too much quinin. Mark the words *is caused* by quinin, not is made worse by it. The present writer heard that address of Koch and remembers well that Koch said he had never seen hemoglobinuria in a patient unless previously treated by quinin. This is, of course, the expression of a man possessed of a most limited experience in malarial hemoglobinuria and there can be no question of the unity of authoritative sentiment against him.

Dr. Hare then takes up the recent literature upon the use of quinin in hematuric and hemoglobinuric conditions. His second quotation is from *La Presse Medicale* for December 3, 1898. He says "Vincent informs us that American statistics demonstrate that the greater number of patients survive that do not receive quinin." Just what the last part of that sentence may mean is not very clear in its loose English dress; the first part is another serious misquotation. What Vincent says is "Les statistiques de *certains medecines* Americains tendent a montrer" ("The statistics of *certain American* physicians *tend to show*" etc.), quite a different thing from "American statistics demonstate." Vincent himself a little further on in the same article advises the use of quinin in doses of 8 to 15 grains even in the presence of hemoglobinuria. Even supposing the original quotation correct, why go to France for American statistics? And who is Vincent that his opinion on malaria should be quoted so seriously?

Dr. Hare quotes Dr. Meek of Arkansas, who protests in the *Therapeutic Gazette* "in the name of humanity" against the use of quinin in malarial hematuria. "In the name of humanity" is expected to add force we suppose to his protest. But if medical editors would publish them we would have in our medical journals no end of protests "in the name of humanity" and everything sacred, against vaccination, antitoxin, and the use of mercury in syphilis and any other good therapeutic agent that can be named. An English medical editor once said in somewhat Johnsonian style: "Intensity of objurgation in matters therapeutic, whether positive or negative, is usually in inverse ratio to the authority of the man who uses it and usually in inverse ratio also to the value of the suggestion he has to offer. It is only a great authority who can commend or condemn a remedy with a mlid judicial spirit." The old editorial formula has not lost all its application even in our day.

This is what Dr. Meek says: "During the first ten years of my professional life I treated quite a number (six) of cases with large doses of quinin, and the mortality was at least fifty per cent. Since that time I

have treated quite a number (sic iterum) without quinin and the mortality has been eighteen per cent." We scarcely think it invidious criticism to say that statistics with inexact percentage mortalities and indefinite numbers of cases are not very valuable to the seeker after medical truth. Dr. Meek quotes Dr. Guise who treated without quinin four patients with malarial hematuria without a death, after having treated twenty-five patients with quinin with a mortality of fifty per cent. Here is something tangible but the number of cases is so small that no practical conclusion from the result obtained is justifiable.

These we suppose are samples of "the statistics of certain American physicians," quoted by Vincent, that tend to show that the mortality of malarial hematuria is less when treated without quinin.

A number of Greek physicians, Karamitsas, Rizapoulos, Pampoukis, and Chamatianos, are quoted by Dr. Hare as having met with cases of chronic malaria in which quinin caused hematuria whenever administered. We find this same collection of names, with Thomaselli and Carreau, whom Dr. Hare quotes also (perhaps from this identical chapter), in Laveran's book in discussing what the French call *fievre biliaire hemoglobinurique* (bilious hemaglobinuric fever). Now this affection is, in Europe, as Laveran tells us, frequent only in Greece. It is very doubtful if it is ever due to uncomplicated malaria. Various microorganisms have been isolated that have been thought to bear an etiologic relation to it. Vincent's experience with it as reported in the article quoted by Dr. Hare is, we believe, not an unusual one. In only one case out of five was Vincent able to demonstrate the plasmodium malariæ in the blood, and in only two out of five autopsies did he find characteristic lesions of malaria. It is probable that certain cases at least of the affection are not malarial at all. The disease occurs very commonly in tropical countries and it is probable that its careful differentiation from purely malarial forms of hemoglobinuria will do much to set at rest any lingering doubts as to the use of quinin in the latter condition. Meantime, such authorities as Osler, Laveran, Bacelli, and Crosse, the latter having seen a great deal of the disease in Central Africa, advise the use of quinin in hematuria and hemoglobinuria if there are present the symptoms of an acute malarial process.

Finally comes the question of malarial nephritis and the use of quinin during its existence. With regard to the frequency of nephritis after malaria Dr. Hare quotes the statistics of the *Journal of the American Medical Association*. These we have already condemned editorially, because they give an altogether erroneous idea as to the frequency of malarial nephritis. Osler found albumin in the urine of 46.4 per cent. of his patients and Thayer found tube casts in 17.5 per cent. of his patients; but Thayer in summing up as to the occurrence of nephritis after malaria in all the Johns Hopkins cases found that among whites the renal affection occurred in only 1.1 per cent. of the patients. To quote the larger percentages as to albuminuria and tube casts without this conclusion is to give the idea that malaria produces nephritis in one out of every six patients or more instead of about one in a hundred cases. We quoted in our article Rem Picci's statistics of 7000 cases of malaria at Rome with 80 cases of nephritis, exactly the same percentage as Thayer found among the whites in Baltimore. These are evidently reliable data; and very much concern about the possible development of nephritis is not demanded of the practitioner.

There remains the question of quinin irritating the kidneys. Quinin has been given freely in innumerable numbers—millions—of cases and it has never been shown that patients who had taken it nad developed nephritis any oftener than people who had not. Dr. Hare says that he has shown that in toxic doses it leads to inflammation of the kidneys. But so do a great many drugs that in therapeutic doses are perfectly harmless. We at least, do not advise the use of quinin for malaria in *toxic* doses.

Dr. Hare has collected from medical literature some twelve cases in which quinin seems to have acted as a kidney irritant. Most of them present at the same time other genito-urinary symptoms, showing that there was some intercurrent source of irritation or that the patients had probably an idosyncrasy for the drug. He surely would not wish us because of these few cases to modify our ideas as to the administration of quinin in malaria. Many cases of skin irritation from quinin might be collected, yet surely no one would argue therefrom that quinin is irritant to the skin in every case and must be administered always with special reference to that fact.

For idiosyncrasy no rules can be laid down and in our presentation of a short article on quinin we did not think it necessary to refer to it at all, leaving something to the good sense of our readers.

After this discussion of Dr. Hare's authorities, since he lays no claim in his article to any clinical experience in the matter that would make his personal opinion of value, we may be permitted to reiterate our former opinion as to quinin in malaria. In cases in which there are convincing symptoms of active malaria the practitioner will err (if it is an error) with the the world's best authorities on malaria in giving quinin freely even though hematuria, hemoglobinuria, or albuminuria be present.

SCIENTIFIC AND EDUCATIONAL REFORMS.

MEDICAL NOTES OF THE JOINT MEETING OF THE AMERICAN PHYSIOLOGICAL SOCIETY AND THE AMERICAN PSYCHOLOGICAL ASSOCIATION, HELD AT COLUMBIA UNIVERSITY, NEW YORK, DECEMBER 29, 1898.

(Continued from page 56.)

PROFESSOR F. S. LEE read a paper on the nature of muscle-fatigue, in which he said that so far it has been the custom to deduce our knowledge of muscle-fatigue entirely from the frog's muscle. By a comparison between the fatigue-curves of the muscles of the frog, the turtle, and the cat he showed that there are special features of the problem for each kind of muscle, so that the general principles as now taught in physiology will require modification.

Fatigue seems to be induced in the muscle by

the presence of potassium lactate produced during muscular metabolism. When this substance is brought artificially in contact with the excised muscle fatigue rapidly develops, as shown by the curves of contraction obtained after electric stimulation. The same effects are not produced by bathing the muscle during its time of activity with sodium lactate or kreatin, though these substances have been claimed to act also as fatigue-producers. Muscle-fatigue would seem to be due, as far as our present knowledge goes, to the presence of potassium lactate, though perhaps other substances as yet unknown are associated in the effect. Fatigue differs from exhaustion, inasmuch as the elimination of the toxic products restores the muscle to its normal condition, while in exhaustion muscle-elements have been consumed and must be supplied again by the slow processes of vital elaboration of nutritional material.

The biologic significance of fatigue then would seem to be that it is a protective process, guarding the muscle against exhaustion by paralyzing function before overexertion can use up too much of its store of energy. The same biologic significance and protective property would seem to attach to brain fatigue, which prevents the much more serious condition of brain exhaustion. No changes can be demonstrated in nerve-cells after fatigue, while after exhaustion Hodge found vacuolation and lessened staining power, especially of the nuclei, so that the need of this protective influence of fatigue can be readily recognized.

G. C. HUBER read a paper on observations on the innervation of the intracranial vessels, in which he presented an extremely interesting and important fact. Some years ago Professor Obersteiner of Vienna published some observations showing that certain nerves had end-plates in the walls of intracranial blood-vessels; not much work has been done on the subject since. Huber has been able to demonstrate a set of medullated and non-medullated nerve-fibers, these last in plexuses, that accompany the blood-vessels. The medullated seem to end in the adventitia and to be sensory nerves, that is, nerves carrying impulses from periphery to center of the nervous system. The non-medullated are distributed to all the intracranial blood-vessels in perivascular plexuses as in other parts of the body. Serial sections show that they terminate in the unstriped muscular wall of the blood-vessels. It seems clear, then, that the same factors that influence, and the methods of action that hold for, vasomotor nerves all over the rest of the body, may be considered to apply to the intracranial tissues also.

PROFESSOR G. T. W. PATRICK of Chicago read a paper on the confusion of tastes and odors. He has had the opportunity, a rather rare one, of making detailed observations in a case of complete anemia, and has availed himself of it to demonstrate the fact that the two senses, taste and smell, overlap each other in function much more than is thought, and that contrary to the general impression, taste seems to count for but little in many things usually thought pertaining to it alone.

This patient, a woman of good intelligence, has been completely anemic from birth, being unable to recognize any of the nine classes of odors under which odorous substances have been grouped. Substances such as ammonia, chloroform, ether, and pyridin she was able to recognize, but this was evidently due to touch rather than smell, so much of these volatile substances coming in contact with the mucous membrane of the nose as to excite sensations in the tactile nerve-endings there.

Substances in common use in the household, though his patient was an experienced housekeeper, she utterly failed to recognize when blindfolded. Milk was usually mistaken for water, barley water, broth, etc. None of the ordinary meat-broths were recognized, and not even identified as broths, unless there was salt in them. Quinin, though the patient had such an aversion for the drug that she refused to allow her medical attendant to prescribe it for her under any circumstances, was pronounced by her, with eyes bandaged, to be pulverized coffee. Shortly before she had mistaken an ordinary decoction of coffee for a solution of quinin. Tea and coffee were utterly indistinguishable to her, though she was a great lover of coffee, and, of course, thought herself a great connoisseur.

Professor Patrick, after making these observations on the pathological subject, tried a series of comparative experiments on her and two perfectly normal, intelligent women. Even with good smelling powers they failed to recognize milk, failed to distinguish meat-broths, mistook one meat for another, veal and pork for turkey and chicken, and the like, when blindfolded. If they held their noses, tea and coffee became not only indistinguishable, but unrecognizable, and were merely said to be bitter. Out of twenty such trials with coffee, only once was it recognized.

Professor Patrick suggests that a great economy in household expenses may be accomplished by merely blindfolding the family before sitting down to table. If the influence of smell is removed by some contrivance at the same time, most of the savory dishes and drinks now so popular may be replaced by the simplest, cheapest materials.

PROFESSOR C. F. HODGE (with H. H. Goddard) read a paper on possible ameboid movements of dendritic processes of cortical nerve-cells. Dr. Hodge has never been very much taken by the theory that would explain certain phenomena of psychology—sleep, hysteria, consciousness, etc.—by movements of the neurons and the making and breaking of connections between them because of contractions or extensions of their processes. It has seemed to him a little like tearing up railroads and tearing down telegraph lines every night in order to shut off communication for the resting hours.

He has attempted to put a question to Nature in the matter, and has gotten an answer. This he presents for what it may be worth, and makes no exaggerated claims as to the scientific value of the answer, though he considers it an encouragement to further serious work along this line. He took two young puppies and killed one of them early in the morning after it had had a good night's sleep; the other he kept awake all day, which makes a

puppy very sleepy and tired by nightfall; he then killed this second one. Preparations of the cortices show in the case of the puppy kept awake all day a certain varicose condition of the dendritic processes of the cortical cells which is not to be found in the preparation from the untired dog. These varicosities may help to explain the cessation of neuronic contact which finally takes place in fatigue when sleep supervenes, according to the theory that attributes contractile properties to the neurons.

At the joint meeting of the Scientific Affiliated Societies the address of welcome was delivered by President Low of Columbia University, who, besides extending a cordial greeting to the assembled scientists, reminded them of how much had been done for education by such meetings and by the coordination of the different departments of education in a large university like Columbia.

Education is taking a more practical form in all departments, and for this modern science and scientific methods are mainly responsible. The meeting of a great body of scientific men is especially welcome to a great university. Those outside of educational circles thoroughly appreciate the practical tendencies in modern education and give them their meed of recognition. An anecdote might illustrate: Two young women were talking of a young man the other day, when one said, "Isn't he brilliant and learned?" The other said, "Well, he explained to me all about all the varieties of mistletoe the other day and the various plants upon which they are parasitic, but when he passed under it he did not seem to recognize it." There is a knowledge that is merely dry and unimproving, but its day is gone by.

Then followed the discussion upon advances in methods of teaching the various sciences. PROFESSOR CONKLIN of the University of Pennsylvania said that the teaching of zoology as at present organized presupposes laboratory work and demonstrations. The merely didactic lecture is practically a thing of the past. The new light that is guiding modern scientific teaching is the intimate union of research and teaching. The value of teaching in science is directly proportioned to its contact with the living sources of scientific advance. The teacher of science, to be successful, must himself be a contributor to knowledge. A new scientific fact discovered in a laboratory is the best possible stimulus to the work of all connected with the laboratory. It used to be questioned whether original research should ever be undertaken in laboratories meant for the training of undergraduates. This is no longer the case, and during the last few years not a few of some of the notable contributions to our scientific knowledge have come from undergraduate laboratories. The laboratory at Wood's Holl has given an excellent practical example of the value of this method. Other schools will advance in just the degree to which they imitate, as far as possible in their curricula, the Wood's-Holl methods.

PROFESSOR HUNTINGTON of Columbia University discussed advances in the teaching of anatomy. The most important feature of advance is the place deservedly given to comparative anatomy. This leads to the cultivation of the true scientific spirit in anatomical work. Time was when the quantity of facts, not the quality of the facts, given the anatomical student seemed to be the ideal of the teacher. This is getting to be so no longer. The museum of anatomy is no more a mere idle collection of curios, a storehouse for anomalies and monstrosities; it has become a library where the student may go for the illustration of the important parts of anatomy. Object-teaching has replaced theory. Demonstrations are given to small numbers of students, so that personal attention is given to each man. The lecture still has a place, but it is a limited one, a preparation of the student's mind for future demonstrations, not as used to be thought, a pouring-in of ready-made information in unlimited quantity. On the other hand, the danger is avoided of thinking that the study of models can replace the explanations so necessary for the proper understanding of the subject, so that the student may not justly say, "I asked for bread, you gave me a model."

PROFESSOR W. T. PORTER of Harvard University spoke of advances in the teaching of physiology. Professor Porter insisted on the thought so well expressed by President Eliot of Harvard that we must train for power, not for information. With the rapid advance in modern physiology and the immense amount of material it is necessary to absorb, in order to have a practical working knowledge of it, our only hope is to train in scientific methods. Certain subjects in physiology should be coordinated with related practical subjects. Laryngology and ophthalmology would especially benefit by this coordination, and would themselves react beneficially upon physiology. This would lead to putting certain parts of physiology later in the course than now, but that is a change not at all undesirable, and the correlation with practical medicine thus gained will be invaluable in the interest it will arouse in physiology.

The force now making for reform is irresistible. It is nothing less than that the mass of knowledge in every department of medicine is growing so huge as to overwhelm both professor and student. The only refuge lies in a more thorough mastery of the scientific method. The medical student must acquire power rather than information. Only thus will he be able to hold a steady course through the baffling winds and cross-currents of a veritable sea of knowledge.

PROFESSOR GAFONG of Smith College spoke on advance in methods of teaching botany. The day of published laboratory guides is going by. The personal influence of men is replacing the influence exercised over the student by methods, and the teacher is becoming the director of interested investigating students.

Death of an Entire Family from Pneumonia.—The following would seem a further demonstration of the infectious nature of pneumonia. Dr. H. Y. Magnum of Metropolis, Ill., died on December 26, 1898, from this disease; twenty-four hours later his only daughter died; three days after, his wife died; the following week his only son died, and information was received on the 10th inst. that the grandmother, the only remaining member of the family, had died—all from pneumonia.

CORRESPONDENCE.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

CELEBRATION OF THE FIFTIETH ANNIVERSARY OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY—DISCREDITABLE PROFESSIONAL ADVERTISING—NEW LABORATORY BUILDING FOR THE UNIVERSITY OF PENNSYLVANIA—BENEFITS OF MINOR PELVIC OPERATIONS—SOME UNUSUAL FEATURES OF MEASLES—THE PHILADELPHIA MEDICAL CLUB — MEDICO-CHIRURGICAL ALUMNI ASSOCIATION — HOSPITAL GIFTS — PERSONAL NOTES — OBITUARY — HEALTH STATISTICS.

PHILADELPHIA, January 16, 1899.

THE Philadelphia County Medical Society began its semicentennial celebration on Saturday evening, January 14th, when Dr. J. Chalmers Da Costa delivered an address. He spoke of the existing conditions in each country and in every phase of life and after a review of the political and scientific status abroad, dwelt upon this country as it was in 1849, the year in which the Society's first meeting was held. Philadelphia, her lawyers, merchants, and physicians, her customs and her achievements of that time, were carefully gone over, and a short description of the personalities of the great medical men of that day was given. A contrast was drawn between the politicians of that day and this, and he stated that the Senate was not then a club of millionaires but a body of law-givers—not law-sellers. A careful review was given of the history of the Society and the good it has accomplished, and of a fight against the political appointment of an irregular physician to have charge of the Philadelphia Hospital. He made a plea for the appointment of a scientific man as coroner who should be authorized to make use of such material as he becomes possessed of and favored, also, the use of our municipal hospitals for clinical instruction. Of the original founders of the Society but one remains, Dr. Alfred Stillé, and Dr. Da Costa paid tribute to his part in founding the Society, and closed his address by recounting the advances in medicine made and those to be made in the future.

On Sunday evening the Reverend Dr. Kerr Boyce Tupper delivered a lecture on the "Ideal Physician" at the First Baptist Church.

Many of the profession in this city received a card a few weeks ago announcing that Dr. ———, Specialist in Female Diseases, could be consulted at such and such a time. The sequel was to be found in a daily newspaper advertisement which contained the man's name who "cured female irregularities." Last week a throat specialist sent cards to many physicians, together with reprints of various articles written by the advertiser, who is a reputable physician. Perhaps the comparison is hardly flattering but this practice of advertising favors quackery and is certainly anything but elevating.

New Laboratory Building for the University of Pennsylvania.

The accompanying illustration shows the proposed new physiologic, pharmacologic, and pathologic laboratory to be erected by the University of Pennsylvania for the use of its Medical Department. The main part of the laboratory building is 192 feet in length, and there are wings running back at each end 128 feet. Large student-laboratories are placed in the wings, while the front of the main building is divided into a number of special research-rooms, offices, and work-rooms of various sorts. On each floor to the rear of the center of the main building there is a special demonstration and lecture-room arranged in the form of an amphitheater. The animal house is a special building two stories high situated at the open side of the hollow square formed by the main buildings and the two wings. The cost of the building and equipment will be in the neigborhood of $300,000, and it is urgently hoped that a large part of this fund will be secured by contributions from the alumni.

At the County Medical Society on Wednesday evening, January 11th, Dr. George E. Shoemaker read a paper on "Some Cases Showing the Benefits of Minor Pelvic Operations," called for, he said, because of the tendency to overlook these minor, lesser procedures. The recorded cases were those in which the cervix was repaired, fissures cured, scar tissue removed, etc., and while it happened that the majority entailed two or three minor operations, some were questionably classed as minor.

In the discussion which followed Dr. Norris said he advocated better diagnostic power on the part of the general practitioner, which would cause him to send, properly, many patients to the specialist and criticised the gynecologic teaching which the student receives to-day, believing that it tends to make him a dabbler and as an instance stated that many men would hesitate to do a plastic gynecologic operation who think nothing of curetting a uterus, yet the latter is, in his opinion, the more difficult of the two, if it be properly done. Dr. Massey objected to Dr. Norris' statement that all women who complain of backache, pain, etc., should be sent to a specialist and believes in more house or office treatment by the general physician and in fewer patients being sent to the gynecologist.

Dr. James H. McKee read a report on "Some Unusual Features of Measles," one feature being the conveyance, beyond any question, of the disease by a third person, who not only had changed her clothing but had also taken a walk in the fresh air before going to the reported case. Another feature occurred in the case of a boy who had recurring attacks of what was apparently true appendicitis—attacks which were so diagnosed by three physicians in consultation. Dr. J. Madison Taylor suggested that this latter condition might have been due to peritoneal eruptions which were first described by an Italian surgeon in 1896. Dr. McKee pointed out the clear symptoms of appendicitis and did not think Dr. Taylor's suggestion was possible in the case under discussion. Dr. Massey called attention to a case of anterior poliomyelitis following measles and Dr. Taylor to the not infrequent occurrence of this affection as a sequel.

The annual business meeting of the Medical Club of Philadelphia, was held Thursday evening, January 12th, at the Bellevue Hotel. James M. Anders was elected president, Charles Burr, 1st vice-president; George E. De Schweinitz, 2d vice-president; Guy Hinsdale, secretary; John Lock, treasurer (re-elected). Wilmer Krusen, H. Augustus Wilson, G. G. Davis and Ernest La Place were elected as additional members of the executive committee. After the election supper was served during which Dr. Burr paid tribute to the memory of the late Dr. Pepper and other speeches were made by Drs. Anders, Hare, Minnick, and Lemuel J. Deal.

The annual election of the Alumni Association of the Medico-Chirurgical College was held on Saturday, resulting as follows: President, Henry Fisher; secretary, George W. Pfromm; treasurer, E. S. Gans. An executive committee was also elected which varies little from that of last year.

Having learned that the Chester Hospital had an indebtedness of $4500, Samuel A. Crozer sent his cheque for that amount to the treasurer last week. St. Timothy's Hospital at Roxborough was also the recipient of a gift last week of $5000 for a free bed, from Miss Jennie Schofield and Mrs. John Dearnley in memory of their father, Uriah Schofield.

Major D. C. Payton, who has had charge on behalf of the Government of the hospital care of soldiers in Pennsylvania, has been offered a professorship in the Medico-Chirurgical College, the Chair to bear the title of Military and Naval Surgery. Dr. F. S. Bowman has been appointed Out-Door Physician of the Second Ward by the Board of Charities and Correction.

At the eighth annual meeting of the West Branch Medical Association, held at Williamsport, January 10th, Philadelphia was represented by Drs. W. M. L. Coplin, S. MacCuen Smith, and Ernest LaPlace. E. O. Kane, was elected president; J. W. Albright, vice-president; J. M. Corson, secretary, and G. F. Bell, treasurer. Arthur E. Bate, a graduate of Jefferson Medical College, died last week aged forty-six years. William S. Frick, a graduate of the same college, died on Saturday last, aged seventy-two.

The total number of deaths occurring in Philadelphia for the week ending January 14th, as reported at the Health Office, was 642, of which number 185 occurred in children under five years of age. The total number of new cases of contagious diseases was 342, reported as follows: Diphtheria, 69 cases, with 25 deaths; scarlet fever, 36 cases, with 5 deaths; typhoid fever, 237 cases, with 22 deaths.

OUR LONDON LETTER.

[From Our Special Correspondent.]

THE BRITISH ASSOCIATION FOR THE PREVENTION OF CONSUMPTION—ANOTHER DOCTOR BLACKMAILED—THE VACCINIA GERM—THE SENTENCE IMPOSED UPON THE BROTHERS CHIMES, OF BLACKMAIL FAME.

LONDON, January 10, 1899.

THE event of the week has been the great private meeting of the British Association for the Prevention of Consumption, at Marlborough House. I say "private meeting," for although its purpose was publicity and nothing medical has more strikingly attracted the attention of the lay public in many months, yet Marlborough House is the London residence of the Prince of Wales and the Society met there by invitation as his guests. His Royal Highness presided in person and the general eye having been thus skilfully riveted upon the proceedings, Sir William Broadbent made an admirably clear and pointed speech explanatory of the aims and hopes of the Association, if only it could enlist the "man in the street" and his family in their crusade. And in this they really seem to have succeeded this time. It was evidently news of a surprising order to the British public that consumption is a curable disease, and the newspapers have taken it up like a pack in full cry. That astute and energetic organizer, Mr. Malcolm Morris, deserves much credit for the skill with which he and his colleagues suc-

ceeded in securing such a strong cast, an excellent stage, and an admirable time for the presentation of the first public scene of their sanitary drama. Such stars as Lord Salisbury, Lord Rosebery and Mr. Balfour were not only present but did their "turn," and the hit of the meeting was made by the Prince of Wales himself, who in his closing speech announced that Her Majesty herself was already a pioneer in the movement, as she had some months ago ordered the slaughtering of thirty head of valuable Jersey cattle at the Home Farm, Windsor, because they reacted to tuberculin. This certainly was a very progressive thing in an old lady of nearly eighty, and English at that, but it borders upon the ridiculous for all the daily papers to piously refer to it as "Her Majesty's sacrifice for science!". Did they expect Her Serenity to go on drinking tuberculous milk, or to sell the diseased cattle for beef?

Anyhow the meeting scored a great success. One sanatorium where wage-earners and clerks can be treated at nominal rates is announced already and more will soon follow, and what is even better the dear people seem to have got a clear idea that consumption is contagious and a notion to guard against its spread.

These be troublous times for doctors of various sorts. First, for the abortionists, who deserve it, but since that time the fancy for suing seems to have spread. Nearly a dozen of our much harried brethren have been before the courts during the past few weeks. Two cases are of some interest, one on account of its rarity, the other as a specially contagious form of a very common annoyance. The latter was the case of a Dr. Wallace, who was arrested upon the old familar blackmail charge of seducing a patient and then producing an abortion to cover the crime. Absolutely the only "evidence" presented at the trial was that the plaintiff had gone to the doctor's office a number of times to be treated for a uterine displacement, with the ultimate result that after a sitting at which the sound was introduced into the cervix, an abortion at about the third month occurred. The patient was sure that the doctor must have "drugged" her or that she had fainted away, but could not tell upon what visit this had occurred, or recall any of the circumstances attending it. Furthermore, her mother testified that Dr. Wallace having been called in haste to the house, found that an abortion had occurred, and had exclaimed, "And I'm afraid it was my fault," which the old harpy neatly and artistically ornamented with the trifling addition, "I could not resist the temptation!" And upon this trashy excuse for a case the doctor was publicly accused of a revolting betrayal of confidence, arrested and held for some time while the sapient Dogberry, before whom he was brought was deliberating how he should be admitted to bail, all because he was a doctor and as such at the mercy of any female shark who chose to consult him professionally. Fortunately, the case was tried before a strong and competent judge who promptly dismissed it at the close of the plaintiff's evidence as, if it had gone before a jury, there's no telling what the result might have been.

The other case was, to say the least, unusual. A physician was ordered by the coroner to make a post-mortem examination of the body of a child which had died rather suddenly. He did so, and testified at the inquest that the child died of congestion of the brain, whereupon the coroner, Mr. Braxton Hicks (he who took Sir James Crichton-Browne so severely to task for revealing the advantages of ptomain and toxins as poisons to the criminal public) produced two other doctors who at his request had made a second post-mortem. They testified that death had been due to pneumonia, and that the skull had not been opened by the previous examiner. Then Mr. Hicks, who considered that the majesty of the British Constitution had been insulted in the person of one of its principal pillars, himself, promptly committed the first doctor on a charge of perjury. But the unfeeling judge before whom the charge was tried promptly dismissed it, apparently upon the curious and rather inadequate ground that it was simply a case of the famous "doctors disagree," but really as a rebuke to the officiousness of the coroner in setting traps for witnesses. He reduced the magnificent Mr. Hicks to a state of speechless fury by remarking that the proceedings of his coroner's court reminded him more of a performance upon the comic operatic stage than of a real court of law.

The death of Professor Kautback, the well-known pathologist of Cambridge, is widely regretted. He was still a comparatively young man, having held his professorship barely a year and a brilliant future seemed to lie before him.

The newspapers are full of the reported discovery of the vaccinia germ by Mr. Stanley Kent of St. Thomas' Hospital, and several enterprising reporters have interviewed the discoverer and made lovely hash of his scientific descriptions of the process. The episode has of course roused the ire of the "antis" who cannot bear to see any aspect of the vaccination infamy attracting the interest of the public away from themselves and their brass band, and they are rushing into print with letters triumphantly pointing out how abominable a thing glycerin-lymph *must* be when even the conscienceless and ruthless doctors are seeking a substitute for it!

Christmas week was most appropriately signalized medically by the magnificent donation of $1,250,000 by Lord Iveagh to the Jenner Institute of Preventive Medicine. The bulk of this sum is to be devoted to the equipping of laboratories and furnishing of grants for research in bacteriology and other biologic sciences auxiliary to medicine. Fellowships both resident and traveling will also be established.

The late meeting of the Pathological Society was chiefly taken up with the presentation of some new methods of blood-staining by Mr. Pakes illustrated by a large number of specimen-slides and also slides showing the hematozoon of black-water fever of which so much has been heard of late. This Messrs. Pakes and Cross regard as an aberrant form of malaria and pointed out that the absence of the parasite from the peripheral blood by no means disproves its presence in the central organs of the body. This was confirmed in the discussion by two members who had had experience in the tropics and who pointed out that in the so-called cerebral form of malaria, no or-

ganisms might be discovered in the surface-blood, and yet after death the capillaries of the brain he found packed with them. Some of these cases in fact were so intensely cerebral in character that it was difficult to distinguish them from apoplexy. The same condition of affairs would be also found in "intestinal" malaria which presents almost the exact symptoms of cholera.

The sentence of twelve years "hard" upon two of the Chimes brothers of "Lady Montrose Female Tablets" fame and seven years upon the other, is regarded as not a whit too severe. But no one has ventured to suggest that the women who "bit" are to be even blamed in any way for their share in the intended abortions.

VALUE OF PRESSURE IN A SURGICAL DRESSING—SEPARATION OF THE LOWER EPIPHYSIS OF THE FEMUR, NEW TREATMENT—SYPHILIS FROM DRIED VIRUS—PANCREATIC CALCULI—PANCREATITIS SET UP BY THE COLON BACILLUS—DOUBLE VAGINA AND SEPTATE UTERUS—EFFECTS OF FREQUENT AND INFREQUENT FEEDINGS.

AT the Medical Society, November 28th, GOULD opened a discussion on the value of pressure in the treatment of wounds. The importance of securing asepsis has directed the attention of surgeons away from other points in the treatment of wounds, and a routine is apt to be thoughtlessly followed. The maintenance of one position for days, for instance, is not at all according to the wont of Nature. He also held that pressure is largely ineffectual for the purposes for which it is employed, that it is sometimes mischievous, and that it can be well and safely dispensed with. Pressure is usually employed to secure apposition of the edges of the wound, to prevent oozing, to lessen serous exudation, to prevent bagging of fluid, to retain muscular contraction, or to prevent the yielding of cicatrices. But for some time past he had abandoned the use of pressure for these purposes and the wounds had healed better and the comfort of the patients had been promoted. For pressure is not always harmless, and without due care may cause sloughing where there is a large flap, as after removal of the mamma. He had also been struck with its inutility in certain cases, as when the edges united but fluid collected beneath the flap. Pressure did not prevent its reaccumulation, but the insertion of a drainage-tube removed the difficulty at once. Pressure need not be resorted to even after such operations as excision of the mamma. Again after laparotomy for removal of large ovarian cysts or for hysterectomy a simple collodion dressing over the wound is better than the mountains of cotton wool and firm bandage which are still largely used. What surgeons have been in the habit of attributing to their therapeutical measures has been the result of Nature's kindly offices.

DORAN said that five years ago he left off strapping the abdominal wall and simply applied a many-tailed bandage. Later he had used scarcely any pressure, but recently he had returned to its use, as it seemed to him that firm pressure favors the expulsion of flatus, encourages the intestinal movements, and hinders the formation of adhesions. The bandage should compress the abdomen as high as the epigastrium or the gas is likely to be imprisoned in the transverse colon.

SHEILD said that while he agreed with much that the reader of the paper had said he still thought that pressure is desirable after certain operations, such as removal of the mamma, and inguinal colotomy—in the latter instance to prevent extrusion of the viscera should there be severe vomiting. He had seen amputation wounds heal without any dressing, and had been struck with the ease with which the process was accomplished.

BEALE admitted the evil effects of pressure in certain circumstances, notably after excision of joints, in which the healing is distinctly interfered with by the pressure.

At the session of December 12th PITTS read an account of two cases in which he had ligated the iliac arteries. In the former of these he ligated the internal iliac for a pulsating tumor of the buttock, either an aneurism or a sarcoma. The affection proved to be the latter and the patient died from extension of the trouble about a year after operation. In the second case the common iliac artery was ligated on account of repeated hemorrhage from a sinus which had existed a long time, and which was of rather doubtful tubercular origin. The operation was the means of healing the sinus. In both of these patients the incision was made in the median line, the intestines were held up out of the way, and the posterior peritoneum was divided. The common iliac was followed downward until its division was found.

At the Clinical Society, December 9th, the discussion turned on the possibility of syphilis being contracted from dried virus. WILLIAMS presented a report of a case in which a primary lesion formed on the tongue of the owner of a set of bagpipes. The pipes had been loaned to a syphilitic subject and then put away for two months, after which they were played on by the owner, and three weeks later the sore on the tongue appeared. Other more-direct sources of contagion were carefully eliminated.

LUCAS said that there is no more improbability in the preservation of activity of dried syphilitic virus than of dried vaccine virus upon an old ivory-point.

GOULD read a paper on a case of pancreatic calculi, one of which obstructed the bile-duct. The patient was a man, aged forty-six years, who, after a six-months' illness, marked by jaundice and umbilical pain, submitted himself to an operation. The liver was greatly enlarged and the gall-bladder distended. An incision was made over the latter and eight ounces of fluid aspirated. Several calculi were found in the duct of Wirsung and were removed by cutting down upon them. The jaundice and pain were not relieved and three weeks later the abdomen was again opened and a large calculus in the head of the pancreas so situated as to obstruct the flow of bile into the duodenum was removed. The jaundice was relieved but the patient died twelve days later. Small abscesses behind the gall-bladder and behind the ascending colon were found at autopsy.

KELLOCK mentioned a similar case, marked by jaundice

and great pain. After a rigor the patient became less jaundiced and a small calculus was found in the stools. The patient gradually sank from exhaustion. There was another calculus the size of a cherry-pit in a dilated portion of the duct in the head of the pancreas.

FRIPP and BRYANT related the facts in a case of acute hemorrhagic pancreatitis. A man, aged forty-two years, was seized with sudden abdominal pain and two days later was in profound collapse. The abdomen was opened but no obstruction was found. Two days later the patient died. The autopsy showed extensive fat necrosis in the omentum, in the fat around the pancreas, and in the subperitoneal fat, both parietal and visceral. The pancreas itself was twice its normal size and was purplish in color. There were numerous hemorrhages in the fat around it. Sections of the pancreas showed rod-shaped bacilli in the blood throughout the organ but none in the ducts. Cultures grew into colonies of pure coli bacilli. It appeared to be a primary acute interstitial inflammation associated with the presence of the colon bacillus and marked by extensive hemorrhage and by secondary necrosis and inflammation of the parenchyma in the immediate vicinity of areas of fat necrosis. The distribution of the bacilli suggested the blood-vessels as the probable channel of infection.

At the Liverpool Medical Institution, December 8th, LARKIN showed a specimen of double vagina and septate uterus obtained from a woman, aged forty-five years, who died from sarcoma of the lumbar spine. She had had three natural labors and in none of them was the abnormality apparently detected. It did not cause her inconvenience in any way. The vaginal septum was thick and fleshy and the two vaginæ were of equal size. There was an os uteri on each side. The uterus was not bicornate but was divided by a thick septum.

At the Bradford Medico-Chirurgical Society, Novemvember 15th, RABAGLIATI read a paper on some effects of frequent and infrequent feeding. He believed that with few exceptions the cause of all the illnesses he had seen for thirty years was too frequent and too abundant feeding. He thought that Ranke's estimate of the food required by an adult per day was sufficiently large, *viz.*, 100 grams of proteids, 100 grams of fats, and 250 grams of carbohydrates, in all about 1 pound avoirdupois of mixed food. He said that three pounds of food a day frequently produces starvation due to over-repletion. He quoted a case of chronic vomiting in a man, aged forty-seven years, who suffered from chronic gastritis, who had been treated by all kinds of gastric tonics and sedatives and by gastric lavage without benefit. He suggested a long fast to the patient. The patient's temperature under the tongue was 96° F. and at the commencement of the fast his weight was 130½ pounds. During the first week the patient took only water, about a pint a day. During the eighth and ninth days he had, besides water, the whey from a pint of milk, the curds being separated by means of rennet. After the ninth day he had a daily allowance of whey from two pints of milk, no restriction being put on him as to water, which he took either hot or cold as he fancied. He never vomited or felt as if he would vomit after beginning treatment on September 1st till the fast ended on October 6th, neither has he vomited since. At the end of the fast his pulse was 65, soft, steady, and regular, and his temperature 98.4° F. He was up and about the whole time, helping his wife with light domestic duties. His weight at the end of the fast was 117¼ pounds; the loss of weight therefore was 13¼ pounds, or an average of 6 ounces daily during the fast. Since the fast he had been eating ordinary food twice daily, taking a total weight of from 12 to 16 ounces each day.

SELECTED ARTICLE.

LEPROSY IN THE HAWAIIAN ISLANDS.[1]

BY D. A. CARMICHAEL, M.D.,
UNITED STATES MARINE HOSPITAL SERVICE.

Origin.—A number of statements are made relative to the introduction of leprosy into the Sandwich or Hawaiian Islands. Some contend that the disease was brought by the natives themselves, who are an offshoot of the great Polynesian race, the Mahori branch, that inhabit the islands that lie to the south and west. It has existed for ages in the islands of Malaysia and in Java and other islands of the great archipelago. Mr. R. W. Meyer, for many years agent of the Hawaiian Board of Health at the leper settlement on Molokai, in his report for 1886, states that he arrived at the islands in 1850, that in 1857 he first heard of the appearance of leprosy among the natives, and that in 1859 or 1860 he saw the first case of leprosy in a young native who died from it in less than three years. The young man's mother took care of him, and, probably in 1868, she showed signs of leprosy, and died a leper at the settlement. The Chinese generally get the credit for its introduction, although this is denied by many observers, and it is a singular fact that few Chinese on these islands have the disease in comparison with the large number of cases which have occurred among the native Hawaiians.

Leper Settlement on Molokai.—In September, 1864, the spit of land on the northern or windward side of the island of Molokai was chosen as a suitable site for the establishment of a settlement for the segregation of lepers. The site is probably one of the most suitable and isolated that could have been chosen for such a purpose. It is surrounded on the north, east, and west by the sea, and the base or southern side is placed beneath a steep pali or precipice, from 1800 to 2000 feet high, which discourages communication with the rest of the island. The first settlement was at Kalawao on the eastern side of the spit of land. It lies in close to the mountains at the rear and is much exposed to the northeast trade winds. Kalaupapa, the more recent and larger settlement, is situated on the plain to the westward, is further removed from the steep cliffs, and is somewhat protected from northwest winds by the crater of Kahukoo. One and three-quarter miles seaward of Kalaupapa is the small village of Ilioki, and midway between Kalaupapa and Ka-

[1]Abstract from the Public Health Reports to the Supervising Surgeon-General, United States Marine Hospital Service, December 30, 1898.

lawao and close in to the base of the mountain is the village of Makanaupapa, both included in the leper settlement. Water is supplied from the Waikolu Valley and piped from thence to the settlements. Storage reservoirs are placed at different points as a reserve in case of accident to the main supply.

The lepers are supplied with a liberal ration by the Government, which for one week comprises the following: Beef, 7 pounds; salmon, 5 pounds; fresh fish, 7 pounds; pai-ai, 1 bundle, 21 pounds net (a native food prepared from the root of the colocasia esculenta, often written "poi"); rice, 9 pounds, with 1 pound of sugar; bread, 8½ pounds, with 1 pound of sugar; flour 12 pounds, with 1 pound of sugar. Children born at the settlement, of leprous parents, receive one-half of the above ration. Monthly rations are also issued of soap, salt, matches, and kerosene oil. Each leper, outside the homes, receives a clothes ration order of the value of $5 every six months, on the 1st of January and July in each year. Many of the lepers have friends outside who supply them with clothes and money. The cost of the settlement to the Government is about $67,000 per year, and the amount expended for segregation and transportation of lepers and maintenance of the receiving station at Kalihi amounts to about $16,640 per annum.

The following table showing the number of lepers at the settlement on Molokai, mortality, and the number on the books at the end of each ten years from 1864, and estimated from the report of the Board of Health for the period ended December 31, 1897, is given below:

Year.	Admissions.	Deaths.	Discharged or unaccounted for.	Number on the books Dec. 31.
1864	141	26	10	105
1874	91	161	8	671
1884	108	168	8	717
1894	128	155	3	1124
1897	124	139	.....	1100

Spread of the Disease.—From 1849 to 1865 no measures were adopted by the Hawaiian authorities for the suppression of leprosy. The intimate living habits of the natives, using the same sleeping mats, clothing, pipes, eating from the same dishes, bad hygienic surroundings, and, above all, a tolerance of the leper—that is, he was treated as a member of the family and never as an outcast—are given as some of the causes aiding in its spread.

In 1852–53 an epidemic of smallpox invaded the Hawaiian Islands and more than 5000 died. Vaccination of the people resorted to during and subsequent to this epidemic is said to have aided in the dissemination of leprosy. The vaccinations, according to competent observers, were made from arm to arm, with humanized virus, and frequently the pulverized scab selected without much care. The vaccinations were done by planters, missionaries, and the natives, owing to the limited number of physicians available. The general opinion among leprologists is that vaccination had little to do with the spread of leprosy; that the disease was not common in those years, and that there was no marked increase in the number of cases, within the usual period of incubation, subsequent to the epidemic of smallpox.

During the residence of Dr. E. Arning here as a specialist to investigate leprosy for the Hawaiian Government an interesting experiment bearing on this subject was performed by him. In 1885 he vaccinated a number of lepers. The vaccination took in 3 cases, 1 tubercular and 2 anesthetic. Both the lymph and crust of the tubercular case contained the bacillus of leprosy, but he could not detect it in the anesthetic cases. Nonhumanized virus has been used in the islands since 1888 and precludes the possibility of transmitting leprosy by vaccination.

Dr. Arning also performed his now celebrated experiment bearing on the direct inoculation of leprosy. By consent of the Government and a condemned criminal named Kenan, whose sentence was commuted to imprisonment for life, Dr. Arning, on September 30, 1884, excised a leprous tubercle from the arm of a pronounced eper and transplanted it to the exterior surface of the left forearm of Kenan. He was confined and kept under daily observation for the four weeks following, and after that once a week for several months, a microscopic examination of the inoculation spot being made each time. After this he was examined regularly once or twice a month. The microscope revealed the presence of the bacillus lepræ in large numbers until the middle of March, 1885. They then diminished in numbers but were present in the scab fourteen months after inoculation. At this time there was nothing in his appearance indicative of leprosy. Pains in the elbow and wrist of the inoculated arm, which existed in 1885, four or five months after inoculation, soon disappeared. There was no marked change in the condition of Kenan until March, 1887 (two and a half years after inoculation). Dr. Brodie, the prison physician, then noticed changes in the right ear and coppery looking spots on the right cheek. In December, 1887, he was examined by Dr. Arthur Morritz and his description given as follows: "General health good; no pain; slight unhealthy wound on palmar aspect of left index-finger is the only abrasion of the skin. Covering the chest, arms, abdomen, and especially the back, is a copper-colored eruption raised above the surrounding skin and giving to the touch a distinct feeling of thickening. The size of the spots vary from a 10-cent piece to half a dollar, and present shapes round, oval, and serpiginous. The backs of the legs and thighs are affected, and on the front of the knees and thighs are serpiginous patches and small plaques. The right cheek, forehead, and right ear are infiltrated with leprous deposit. Eyebrows show no sign of diminution. The ulnar and popliteal nerves are thickened. Kenan was afterward removed to Molokai and died there. This experiment of Dr. Arning was widely accepted as proof of the inoculability of leprosy, but Mr. R. W. Meyer, for many years superintendent of the settlement of Molokai, states there were lepers in Kenan's family. His mother-in-law, Pulu, died of leprosy in July, 1891, and Kenan's own son, Josepha, was at the leper settlement long before Kenan

himself became a leper, and died there in December, 1893. Kenan's nephew, David, a son of Kenan's sister, also died of leprosy at the settlement in July, 1890."

Other Modes of Communication.—Kissing, nose-rubbing, cohabitation, reception of the secretions from lepers on abrasions of the surface of the skin or by inhalation, deglutition, or transmission by insects. In many of the tubercular cases and some of the anesthetic variety, the lips, cheeks, tongue, arches of the palate and nose are the seat of numerous leprous ulcers, and it is claimed that they also exist in the intestines. The bacilli are readily given off from these ulcers, and it is said can be communicated when a suitable soil is presented, such as abrasions of the skin and mucous membrane, catarrhal conditions, etc.

The natives eat poi, or pai-ai, from the same dish with the fingers, and a leper in the circle with digital leprous ulcers might convey it to the others. The opinion prevails in Hawaii that the disease is not communicated by cohabitation with lepers, but leprologists admit that in the early stages of the disease, when it is not well defined on the surface of the body, leprous patches may be present on the genitals and given an abrasion or suitable soil it is reasonable to infer that transmission in this manner is not impossible.

It is suspected that certain insects play a part in the transmission of leprosy, the common house fly, mosquito, and bedbug being the principal carriers of the infection. The house fly is now prominent as a disseminator of typhoid fever and septic affections, and it is not difficult to imagine that an active part can be taken by this insect in the spread of leprosy, particularly where they can pass from open leprous ulcers to other individuals who may present a suitable soil for the reception of the bacillus. I am not aware that any bacteriological investigations have been made in this matter relative to the house fly. The mosquito is also considered as the disseminator of certain diseases, and some light has been thrown on the influence it may have on the transmission of leprosy by Dr. L. F. Alvarez, the leprologist of the Hawaiian Government. He allowed mosquitoes to alight on the open sores of lepers, and when they had feasted themselves they were captured, killed, and stained preparations made from their crushed bodies contained leprous bacilli in large numbers. Mosquitoes are present in the Hawaiian Islands throughout the entire year. Until the life history of the bacillus lepræ is worked out and isolated cultures obtained, the powers of resistance of the organism to external agencies will remain unknown, but it is believed to be very resistant, and it may exist in a spore condition in the soil, on clothing or other fomites and on the surface of various articles.

Immunity.—All persons are not susceptible to leprosy, and most of the white race seem to have a certain immunity, and if the disease can be conveyed by cohabitation the white sailor seems secure. Many women have lived in intimate relation with leprous husbands and husbands with leprous wives, and failed to contract the disease. A number of the kokuas or helpers on Molokai have lived among and associated with lepers for years and escaped. Bearing on this question, Dr. A. Morritz says: "The washwoman for the hospital at Kalawao has washed the soiled clothes of lepers, the worst cases, for seventeen years, she had lepers living in her house, and her two husbands were lepers for years before they died, and yet in spite of all this contact this woman is hale, hearty, and plump, and as fine a specimen of womanhood as any in the island."

Heredity.—At one time much importance was attached to the theory of heredity in this place but in the light of the present day it is considered an exploded theory. A person has only to visit the Kapiolani Home at Kalihi and see the healthy female children born in the settlement of leprous parents (one or both lepers), and ranging in age from three to twenty years, to be convinced that there is little in the theory of heredity. In contrast with this and an additional argument in favor of contagion is the fact that if these children, born of leprous parents, and without a blemish, be left with their parents and associate with lepers they contract the disease.

Medical Treatment.—The Hawaiian Government with a liberality which is deserving of high praise, has made every effort to employ different measures vaunted as cures for leprosy. Their own physicians have tried many remedies, and in 1883 Dr. Edward Arning of Switzerland was induced to come to Hawaii and serve the Government as a specialist to investigate the subject of leprosy. He accomplished much in the line of investigation, but little relative to curative treatment. He resigned in 1889, and was succeeded in the same year by Dr. A. Lutz of San Paulo, Brazil, a pupil of Dr. Unna of Hamburg.

Under the influence of good food, improved hygienic surroundings, and treatment of a tonic nature the disease improves and sometimes is arrested, in a manner similar to cases of tuberculosis, but the tendency to relapse is great and the cases of aborted leprosy are not numerous. Among the medicinal remedies most valued here are sodium salicylate, salol, creosote, gurgun and chalamoogra oils, pyrogallic acid, crysarobin, ichthyol, lysol, and mercurials in cases associated with syphilis. Dr. Alvarez has tried a bouillon prepared from a culture of the bacillus prodigiosus used as an injection once daily, beginning with 12 c.c. and increasing gradually until 80 c. c. were used. This was tried on 12 leper boys brought from the settlement at Molokai, and the experiments extended over a period of three months. At the end of the period the boys were examined by the medical board and two of them declared free from leprosy and returned to their homes. Another showed marked improvement, but the condition of the others was not changed. He also tried thymus and thyroid-gland extract and dry powder. The result was negative in the case of thymus, but from the thyroid gland were satisfactory. He has also tried the serum of Dr. Carrasquilla of Bogota, Columbia. Temporary improvement in all and marked benefit in one case resulted, which continued for six weeks, "the tubercles which had covered his face, ears, and chest had, with very few exceptions, disappeared entirely." Baths of various kinds, including the Goto system have also been tried. They are all beneficial, but not curative.

Precautions Necessary to Prevent the Introduction of Leprosy into the United States from the Hawaiian Islands.—The period of incubation in leprosy is so long and variable, from three to seven or ten years, its detection in the early stages so difficult, and the fact that leprous patches may first appear on the unexposed parts of the body, such as the upper parts of the arms, chest, back, and nates, and that leprous ulcers may be present in the upper part of the nasal passages, makes its detection by ordinary quarantine methods uncertain. In pronounced cases detection is easy, but these rarely emigrate and the greatest difficulty would be met with in the slight cases occurring in the white or mixed races. The native Hawaiian rarely emigrates, and those who leave their homes generally go as sailors, although I have been informed that there is a small colony of Hawaiians in Salt Lake, Utah. It is possible for persons with leprosy undeveloped, and for the slighter cases, to pass from one country to another without detection, and the fact of its presence in various parts of the United States is evidence that quarantine restrictions do not exclude it. Few medical men are familiar with the appearance of leprosy in its early stages, and cases are often diagnosed as other skin diseases, and the fact that skin diseases, such as psoriasis, various forms of tarina, chloasma, scabies, erythema, etc., are often associated with leprosy, makes its detection still more difficult.

Restrictive measures should be adopted to control the departure of all emigrants from endemic foci of leprosy at the point of departure, and these should consist of a careful inquiry into the family and sanitary history of each emigrant, a rigid physical examination and disinfection of his effects. Similar procedures at the port of arrival should be adopted and a record of the destination of the emigrant preserved. Adoption of the above-named measures would restrict the importation of the disease so far as it is possible to do so, but such proceedings could be still further aided by the Government of the United States assuming control of measures for the suppression of leprosy in the possessions recently acquired by annexation and by conquest, *viz.*, the Hawaiian and Philippine Islands and the island of Cuba, in all of which leprosy exists to a greater or less extent.

REVIEWS.

A CLINICAL MANUAL OF MENTAL DISEASES. By A. CAMPBELL CLARK, M.D., F.F.P.S.G. New York: William Wood & Company, 1898.

THE very numerous text-books on insanity from American, English, and German sources which have appeared within the past five years were apparently considered by the publishers of this manual as insufficient for the needs of the profession, or as scientifically inadequate to reveal to medical men the status of psychiatrical science. When a publishing firm undertakes the issuance of a scientific work it should do so with some show of reason. That this book demonstrates such a reasonable motive may be doubted, for it is scientifically inadequate in all the departments of psychiatrical science. If any department of psychiatry is well exploited, it is the clinical, and of clinical pictures of the various forms of mental disease we have in literature not only more than enough, but all, without exception, the equal, if not the superior, to those of this manual. The work is primitive and of little scientific value.

THERAPEUTIC HINTS.

For Rhinopharyngitis in Young Children.—A simple procedure for local treatment is recommended by GASTON, *viz.*, the introduction into the nostrils, three or four times a day, of a cotton tampon rolled to a point, covered with borated vaselin, with or without the addition of an astringent, such as the following:

℞	Antipyrini	gr. viii–xvi
	Acidi borici	gr. vi
	Vaselini	ʒ v.

M. Ft. ungt. Sig. External use.

If the child greatly objects to the tampons, one or two drops of the following mixture should be instilled into each nostril night and morning:

℞	Menthol	gr. viii
	Ol. amygdalæ dulcis . . .	ʒ i.

M. Sig. External use.

If direct treatment of the pharynx seems indicated, it may be swabbed with iodin in glycerin, equal parts, or with the following mixture:

℞	Iodi	gr. vi
	Potassii iodi	gr. xxx
	Ol. menth. pip.	gtt. iv
	Glycerini	ʒ v.

M. Sig. External use.

For Pruritus of the Vulva, in pregnancy, ichthyol, in the form of ointment (fifteen per cent.) or watery solution (ten per cent.) has been found to effect a cure after all other means of treatment, such as antiseptic douches, lotions, and ointments have been tried without success.—*Doizy.*

An Agreeable Antiseptic Dentrifrice.—

℞	Salol	gr. xlv
	Ol. anisi } aa	*m.* viii
	Ol. geranii }	
	Ol. menthæ pip.	*m.* xv
	Spiritus	℥ v.

M. Sig. Dentifrice.—*Noguć.*

Administration of Opium to Children.—The wine of opium is mentioned by NOGUÉ as a suitable preparation in the following doses:

Up to 6 months	½ drop
From 6 months to 1 year . .	1 drop
From 1 year to 2 years . .	2 drops.

Increase one drop per year of age. These doses may be repeated half-hourly when indicated.

Wine of opium may also be given in an enema, 2 or 3 ounces of a suitable vehicle being employed, in doses as follows:

From 1 to 2 years . .	1 to 3 drops
" 3 to 5 " . .	5 to 10 "
" 5 to 10 " . .	10 to 30 "

ORIGINAL ARTICLES.

THE DIAGNOSIS AND SURGICAL TREATMENT OF RENAL CALCULUS.*

BY NATHAN JACOBSON, M.D.,
OF SYRACUSE, N.Y.:
PROFESSOR OF CLINICAL SURGERY IN SYRACUSE UNIVERSITY; SURGEON TO ST. JOSEPH'S HOSPITAL.

IN considering renal calculus from a surgical standpoint there are several questions to be answered: First, are we, in a given case, positively dealing with stone in the kidney? Second, when does its presence demand surgical intervention? Third, what operative procedure does the case require; and finally, what are the results of the surgical treatment of renal calculus?

The more we familiarize ourselves with the manifestations of renal stone, the more evident it becomes that the classic symptoms set down in the books are not always present. In one instance stone may be present for a long time without awakening symptoms, in another they may be most distressing. This variation depends upon the location and character of the calculus. Lodged at the base of the pyramids, or in the recesses of the calices, there may be no manifestations whatsoever. Lying free in the pelvis of the kidney, acting like a ball-valve and occasionally producing obstruction, there may be at an early period both hemorrhage and colic. Not until, by its presence, the stone has produced a certain degree of irritation in the kidney can marked signs of disturbance be expected to occur. The history of most of the cases coming to the surgeon's notice indicates that the trouble has existed many years. Of ten patients presenting themselves for operation at the clinic at Heidelberg,[1] five had had trouble since earliest childhood, covering a period of from seventeen to thirty-nine years, and in only a single instance had it been of as brief duration as two years.

Assuming that we have to deal with stone, we are at once reminded of the fact that as constitutional conditions are responsible for the calcareous formation, both kidneys are apt to be simultaneously involved. In other cases, renal colic may appear in one kidney much earlier than in the other. With such a history, were complete anuria to occur, experience has taught that the kidney last presenting evidences of trouble is probably responsible for the suppression. Some writers question the possibility of the inhibition of renal function in one kidney as the result of the presence of stone in the other. There is no doubt whatsoever that such a condition of things does occur. For example, in a case published by Israel,[2] in which complete anuria had existed for four days, overcoming the obstruction in the left kidney permitted free discharge of urine from both. That this in reality took place was evident by comparison of the urine accumulating in the bladder with that flowing out of the wound in the kidney. The latter contained a larger percentage of coloring matter, more albumin, and had a much higher specific gravity than that discharged from the bladder. At the same time it is of interest to note that many times obstruction in one kidney awakens manifestations which make evident the presence of stone in the other. To illustrate this, I may recall a case reported by Mr. Herbert W. Page.[3] The man had both vesical and renal calculi so it became necessary in turn to remove the stone from the bladder, to enter his left kidney, and later on to open the right one. The three operations were performed at intervals of about one month.

Attention should be called to the fact that during the period in which the calculus is hollowing out for itself a nest in the kidney a degree of pyelitis is aroused, apparent in the presence of pus in acid urine, but when the nesting process has been completed and the calculus has found a comfortable resting place, the pus disappears and the patient enjoys so great a degree of comfort that he thinks himself cured. This process may cover a period of years. On the other hand, in an individual not possessing the necessary resistance, or when a tubercular condition may have developed renal abscess, suppurative destruction of the kidney may advance and extending through the very substance of the organ may produce abscess in the perinephric structures.

Because of the wide anastomosis of the renal nerves, pain is one of the most uncertain manifestations attending this condition. Dr. Dickinson[4] tells of a young woman who died at St. George's Hospital. Both kidneys were occupied by large, rough stones. The bladder and urethra were perfectly normal, yet her distress was almost entirely vesical. No less eminent a surgeon than Dr. J. William White of Philadelphia reports a case[5] in which he and the

* Read before the Onondaga County Medical Society.

learned editor of the *American Journal of the Medical Sciences* had undertaken an operation for the relief of what both of them had diagnosticated as appendicitis, but finding the appendix perfectly normal, sought further for the cause of trouble and found a stone in the ureter. The history of this case was that of severe pain in the lower portion of the abdomen and groin of the right side; the thigh was flexed; the patient had vomited on the evening of the attack and continued to do so for the two succeeding days. On the second day there was distention of the abdomen and constipation; in the evening the patient had a chill with considerable increase in the abdominal distention. Severe cutting pain in the right side of the abdomen followed an enema. There was fever throughout, and during the chill it reached 104.2° F. Decided fulness could be made out well down in the right side of the abdomen. W. F. Brook reports a case[6] in which the most acute pain was at the McBurney point. I had occasion recently to know of a man who, after intense right-sided abdominal pain, the diagnosis being appendicitis, discharged a renal calculus.

In the article referred to, by Dr. White, a list of the conditions appears which strikingly simulate renal stone, one of them, a case of spinal caries[7] in which there was unilateral rigidity, testicular pain, intermission of symptoms, increased frequency of urination, nausea during the attacks, and oxaluria with local pain and tenderness. Erichson,[8] as well as W. H. A. Jacobson,[9] and others, have had similar cases. Subphrenic abscess, due to appendicular disease, has been mistaken for perinephric abscess. One such case I have seen. Duodenal ulcer and intestinal irritation have provoked symptoms similar to those of renal calculus. Malignant tumors of the cecum have been mistaken for diseases of the kidney, and Morris reports a suppurating condition secondary to malignant disease of the sigmoid flexure as having been mistaken for renal abscess. Hemorrhage from the kidney not the site of stone can in consequence of the obstruction due to the presence of clot awaken symptoms strongly suggestive of renal stone. Grosglik[10] published recently an article in which eighteen reports of cases of hemorrhage from presumably healthy kidneys were gathered from medical and surgical literature, some subjected and others not to operative procedure; in all, with two possible exceptions, no organic disease could be found to account for the presence of symptoms similar to those of renal calculus. Some of these were subjects of hemophilia. Locomotor ataxia[11] and "hepatic neuralgia,"[12] have in turn been mistaken for stone. Franks refers to a woman who had both ovaries removed. No relief from her trouble was experienced until a stone was extracted from her kidney.[13] Ransohoff[14] collected forty-four recorded cases in which operations for stone in the kidney had been performed and in none of which stone was found. Two of these subjects, dying later, upon post-mortem examination, nevertheless, showed the presence of stone in the kidney. The differential diagnosis between tuberculous and calcareous disease of the kidney, especially at an early stage, is not always easily made.

This brings us to the question of the recognition of stone after exposure of the organ. In many cases palpation of the exposed organ fails to reveal the presence of stone. Routine puncturing of the organ until finally every part of the kidney is believed to have been searched does not always discover the presence of stone even where at a later period it was shown to have existed. For this reason Weir,[15] in one of the series of papers covering his personal experience in renal surgery, recently published, as well as before the New York Surgical Society, stated that the method of detecting stone by puncture is most unsatisfactory. He regards as much more reliable an incision into the kidney and the examination of the organ with the finger or a sound. The ureter can at the same time be explored with a metallic probe. It should be eighteen or twenty inches in length as this canal stretches under pressure.[16] Mr. Morris calls attention to the fact that under the pressure of stone the kidney becomes hard and tough. An exposed kidney found to be exceptionally hard is always to be suspected of harboring a calculus.

In connection with this matter it might be stated that multiple stones are frequently encountered in the same kidney. It is necessary, therefore, after clearing out the pelvis in every instance, as Israel was the first to indicate, to recognize the necessity of searching the ureter to determine that its passage is free. It has occasionally been possible when stone has been found in this canal to force the calculus up into the kidney or down into the bladder by gentle kneading. The presence of multiple stones has in a few cases been recognized before operation by the bimanual manipulation of the kidney. A grating sound resulting from the friction of one stone upon another is produced. Singularly enough, however, Stimson reported to the New York Surgical Society in November, 1897, that he obtained in a given case distinct crepitus; the kidney, however, when opened presented but a single stone.

Parenthetically it might be observed that the most common form of renal calculus is the uric-acid stone, the next in frequency, the oxalate of lime. The

latter is particularly the one which is apt to occur singly; the other forms are much more certain to be multiple. The stone which appears in infancy is usually made up of urate of ammonium. Mr. Thomas Taylor, who made the analyses of the calculi of the Hunterian Museum, proposes to call stone with this nucleus the infantile calculus, and those with uric acid the calculus of young adult life. The oxalate-of-lime stone, he says, is encountered usually after the fortieth year.

The difficulty in positively determining the presence of stone in the exposed kidney has led Fenwick [17] to resort to the use of the Röntgen-ray for examination and discovery of the same. The difference of the transmissibility of light, however, of the different calculi make it of doubtful utility. The oxalate-of-lime calculus is the only one which gives a good shadow. Both the uric acid and the phosphatic stones are too readily penetrated by light waves. Other disadvantages of this method of examination are clearly stated by the investigator. The examination of the unexposed kidney through the loin has not been as yet at all satisfactory.

Discussing still further the indications for operation it may be stated that absolute dependence cannot be placed upon examination of the urine. The presence of pus, blood, and a marked excess of urine salts in an acid urine, together with a clinical history of lumbar pain, attacks of colic, radiating down the course of the ureter, associated with temporary suppression of urine strongly indicate the existence of stone in the kidney, but it is too well known that even extensive disease in the organ can occur without positive urinary evidence to make one depend too much upon urinanalysis in calculus disease. For example Weir [15] removed a stone an inch by three-fourths of an inch in diameter, weighing 112 grains, and with it forty smaller ones from a patient who for ten years had had right-sided renal colic with the frequent passage of gravel. For two years he had almost constant lumbar pain, yet the urine showed nothing characteristic of stone, and in fact contained no pus.

I trust that it will not be inferred from what I have here stated as to the difficulty of making a correct diagnosis in many cases that surgical operation for renal stone is not justified. On the contrary, the surgical treatment of no organ has been more satisfactory than that of the kidney. I desire to indicate simply the need of a searching diagnosis.

Not so many years ago, in fact within the recollection of most of my hearers, the kidney was looked upon as one of the organs which the surgeon had no right to select for attack. After careful experimentation upon the lower animals, Simon of Heidelberg, in 1870, first attempted the removal of the kidney from a human subject. It was ten years later that Czerny undertook the same operation for the relief of stone in the kidney. In the same year, 1880, Mr. Henry Morris was the first to invade the kidney for the removal of stone, and at the same time to preserve the integrity of the organ. The operation of nephrolithotomy as introduced by him at that time is altogether a justifiable surgical procedure. As he well points out,[4] a marked distinction should be made between nephrolithotomy and nephrotomy. Nephrotomy simply implies the incision into the suppurating sac built up of the remnant of a kidney and differs decidedly from the procedure he suggested for the removal of stone while the kidney is still in a condition of possible preservation. The indications for the latter, to borrow his words are: "The operation should unhesitatingly be done in all cases in which symptoms of renal calculus continues uninfluenced by medicinal treatment, and are sufficiently severe to interfere materially with the comfort and usefulness of the patient's life. If for several months a person has been subject to more or less constant pain in one loin and along the ureter, and perhaps also in the testicles of the same side, if there have been recurring attacks of renal colic, and especially if with these symptoms there has been occasional hematuria, or the urine has been constantly charged with a little pus or albumin, we have the conditions not only justifying but demanding an operation."[16] Few, perhaps, would go so far as does White [5] in saying that the operation is indicated as soon as renal calculus is diagnosed.

Certain it is that by the lumbar incision the kidney is very easily reached. Its exposure is but the work of a few minutes. With careful preparation there ought to be no danger of suppuration nor subsequent septic disturbance. A variety of incisions have been suggested in the loin. I prefer the incision which extends obliquely downward, perhaps four inches in length, from the twelfth rib toward the crest of the ilium. By means of a pillow, or better still, Edebohl's air-bag placed against the abdomen, with the patient in a semiprone position, the kidney can be readily forced into the loin and made accessible. Except when it is necessary to remove large tumors, the opening of the peritoneum is not required. The fatty investment of the organ is speedily reached and the kidney exposed. The further steps in the operation will depend upon what is discovered. If the stone is not superficially located, it will be necessary to incise the entire organ and enter the pelvis. The stone can best be enucleated with the finger or removed with bullet-forceps or scoop, or if branched, broken up and re-

moved in segments. If unnecessary to invade the pelvis this should not be done, as an opening into this space certainly increases the danger of permanent urinary fistula. The introduction of the finger controls renal hemorrhage to a certain extent. If there is no suppuration, and the surgeon has been fortunate enough to remove the stones and leave a clean surface, the kidney can be sutured, and primary union expected,[18] but if the calculus disease has been sufficiently severe or long continued to provoke suppuration, it is evident that repair by first intention cannot be anticipated.

It becomes a very serious question as to where the line justifying nephrotomy or demanding nephrectomy is to be drawn. Recently a number of the German clinicians have published their experiences in renal surgery, and it is but fair to conclude that when there is extensive destruction of the kidney the removal of the entire organ has yielded better results than simple incision. Herczel, publishing the statistics of the Heidelberg clinic in 1890, was able to report twenty-nine cases of nephrolithotomy in which 26 of the patients were definitely cured, and in which there were, therefore, but 3 deaths. In the same article he quotes Brodeur, who reports 23 lumbar nephrolithotomies with but a single death, and the same writer referring to the suppurating cases, quotes 13 lumbar nephrotomies in which 7 patients died, and 3 by the abdominal route, all terminating fatally. On the other hand, where for the same condition of widespread suppuration and destruction of the kidney, the organ was removed by the lumbar route in 34 cases 19 patients were cured, while of 10 removed by the abdominal route 5 were cured. Apparently, then, for this condition a slightly better result has followed the removal of the organ than its mere incision, depending upon Nature to cast off the débris.

And yet great dangers may be encountered in the attempted removal of the kidney closely adherent to the surrounding structures. It is impossible to determine how far reaching these adhesions may be. In a number of cases the vena cava has been torn open or cut into by the bite of the forceps which embraced the pedicle of the kidney. Such a laceration occurred in a case of Weir's.[18] He recognized its nature promptly and brought the large vein up into the wound. It was put upon the stretch and compressed and the laceration closed by a running suture. His patient recovered without the formation of a thrombus or venous obstruction. He, however, was more fortunate than some other operators have been. Fatal results attended the same complication at the hands of Enderlin,[15] Thornton,[16] and Bräuninger.[19]

Hildebrand[20] reports an operation upon a large pyonephrotic tumor which filled the left half of the abdomen. The tumor was movable, not affected by breathing, its surface was smooth, and the wave of fluctuation extended from before backward to the lumbar region. The urine contained a rich sediment of pus-corpuscles, cholesterin crystals, and a large percentage of albumin. This enormous renal sac contained half a pailful of purulent but not odorous fluid. Connected with it was an accessory cavity filled with stones. These were light, friable and phosphatic. The size and adhesions of the sac, the operator believed, would have rendered an attempt at its removal fatal, while its incision and fixation resulted in a very satisfactory recovery.

The danger of mercurial irrigation in these operations was well brought out by a case in the hands of Edmund Owen.[21] The mercurial poisoning was so profound as to almost cost the patient his life. Fortunately, however, he recovered. Gauze drainage is to be used when suppuration is feared, but it is to be lightly introduced, for packed into the wound it is said to have caused death at the hands of some operators by pressure upon the nerves of the mesocolon and against the parietal peritoneum, by producing intestinal paralysis.

Briefly summarizing, then, the surgical aspect of renal calculus, it can be said that with the diagnosis positively established, with the futility of medical treatment conceded, invasion of the kidney is not only justified but demanded. The earlier this fact can be recognized the better the result. If nephrolithotomy can be performed before the kidney has undergone marked destructive change, not only can a useful organ still be preserved, but the fatality attending such operation is ordinarily not more than ten per cent. On the other hand, with marked enlargement of the kidney, because of the accumulation of water or pus in what has become a renal sac, with a fair amount of tissue still remaining which can perform its function normally, nephrotomy is to be performed. If there has been extensive destruction of the organ, or numerous calculi invade widely the kidney, and if the surgeon is assured of the presence and activity of its fellow, the better course, if the adhesions are not too great, is the removal of the organ. The mortality attending these latter procedures is enormously greater than that of nephrolithotomy, reaching in skilful hands as high a rate as fifty per cent. There can be no longer a question as to the safety and accessibility of the lumbar over the abdominal route.

A LITTLE EPIDEMIC OF POLIOMYELITIS.

BY LEO NEWMARK, M.D.,
OF SAN FRANCISCO, CAL.

NOTHING affords more support to the theory of the extrinsic origin of an organic disease than an epidemic of it. Charcot[1] was expatiating once on the hereditary antecedents in cases of acute anterior poliomyelitis, with the purpose of showing its membership in the "grande famille neuropathologique," when Cordier's account of an epidemic of this disease made him pause. He was unwilling, however, to infer the infectious nature of the malady without some reserve, saying that "this very curious history of a little epidemic of infantile paralysis constituted an episode absolutely isolated." Since then other epidemics of greater and less range have been reported, and I desire to add in the following an account of a group of four cases, for which the appellation "epidemic" may seem rather grandiloquent, but which may, perhaps, serve in some measure for the elucidation of the etiology as well as a larger number of cases. The village in which three of these cases occurred, and near which the remaining one was observed, is stated to have only forty-nine inhabitants, so that four represents a not inconsiderable proportion of the population. This place is Le Grand, situated in the San Joaquin Valley, in Merced County, California.

CASE I.—June 2, 1898, in the morning, Irving J., a boy aged eight and one-half years, complained of backache and had fever. He continued to walk about, but refused food. At 2 P.M. his temperature was 102.5° F. On the following day he was unable to walk.

CASE II.—On June 6th, Louis J., a brother of the preceding, aged ten years, complained about noon of an ache in the knees. At night his temperature was 102.5° F. He was able to walk as late as 10 P.M. The following morning he could not move his lower extremities at all, and handling of them caused pain. There was retention of urine and great prostration until about the eighth day of his illness.

There is one other child in this family, a boy older than either of the patients, who is a deaf mute, and at the time of his brothers' illness he was in an asylum for the deaf and dumb.

CASE III.—On the tenth of June, in the evening, a boy eight years of age, the son of a physician who attended the J. children, a constant playmate of the latter, was seized with pain in the back, headache, and fever. The temperature ranged from 101° to 104.5° F. for two days and nights, and then gradually fell to normal. There was frequent desire to urinate. Pain and stiffness in the elbows, wrists, and shoulders were complained of. On the second day partial paralysis was observed in the left arm and leg. Power was completely regained over the leg, but the arm has remained affected.

Drs. McMaster and Robertson of Le Grand, to whom I am indebted for the foregoing histories, also kindly furnish me with the notes of:

CASE IV.—On a farm, three miles distant from Le Grand, a robust lad, fourteen years of age, having become suddenly ill with fever, headache, and nausea on the 2d of August, was paralyzed almost completely, without anesthesia, in the lower extremities; on the morning of the 4th was partially paralyzed in the left arm, and troubled with difficulty in urinating on the 5th, and the muscles of respiration becoming involved, he expired on the 8th. Irving and Louis J. were brought to San Francisco, and I saw them on the 25th of last July. This was the only opportunity I had of examining them. Irving J. was able to walk briskly, but with a swaying gait. When he walked there was overextension of the knees, and the left foot was moved in a flapping manner. He could not rise from the recumbent position without considerable effort, and, in order to regain the erect position when rising from a sitting posture on the floor, he pushed the trunk up by resting his hand on the thigh. The region between the lowest rib on the right side and the crest of the ilium exhibited marked wasting. Extension of the knees was slightly enfeebled, as was also flexion of the left one, nor were extension and flexion of the left ankle and abduction of the left thigh executed with normal force. The knee-jerks were about normal. Distinct failure to respond to the faradic current was noted only in the left tibialis anticus among the muscles of the lower limbs.

This lad stutters considerably. His brother, Louis, presented an almost complete flaccid paraplegia. He could not extend the big toe of the right foot, but he could extend the others, and was able to flex them all; on the left side only very feeble flexion of the toes was possible. While he was capable of some flexion and extension of the right ankle, in the other these movements were lost. The other movements remaining in the lower

[1] *Leçons du Mardi*, p. 146, 1888–1889.

extremities were very slight flexion of the knees, a little extension of the right hip, a fair degree of outward, and much less inward, rotation of the right thigh. The knee-jerks were absent.

In the right leg faradic contractibility was preserved in the peronei, in the extensors of the toes and in the posterior tibial group; it was absent in the tibialis anticus. No response was elicited in any muscle on the left side below the knee, nor in either extensor quadriceps.

Neither of the boys exhibited anesthesia. Despite the incompleteness of the examination, owing to lack of opportunity, the diagnosis of acute anterior poliomyelitis in these cases is, I think, warranted by the facts communicated.

I have not seen the third patient at all, but Dr. Philip King Brown of San Francisco saw him at Le Grand and observed paralysis and atrophy of the intrinsic muscles of the left hand and of the deltoid.

The fourth, fatal, case seems to have been one of acute ascending paralysis, undoubtedly due to a myelitic process.

Inquiries addressed to a majority of the physicians practising in Merced and two adjoining counties, concerning the recent occurrence of acute organic disorders of the nervous system elicited no information tending to prove a wide dissemination of these diseases at the time of the appearance of the cases at Le Grand. One other case of poliomyelitis was reported as having occurred at the end of May in a boy of ten years who dwelt in the same county, but at a considerable distance from the little epidemic. It may be worth mentioning, however, that in the beginning of last March at Los Baños, a village of 450 inhabitants, situated in Merced County, but quite remote from Le Grande, six persons were seized with cerebrospinal meningitis.

Great influence has been attributed to heredity in the etiology of acute anterior poliomyelitis by some writers—by a majority of them according to Marie[1]; and the multiple occurrence of the disease in a family was thought corroborative of such a view. In the little series described in the foregoing not only were two brothers affected with the disease, but the stuttering of one of them and the deaf-mutism of a third brother may be considered as evincing their hereditary neurotic taint. The extension of the affection, however, to their playmate, who is in no way related to them, proves that in household epidemics of this malady it is propinquity in regard to locality and not to blood-relationship that determines the spread of the disease among near kin.

In its usual mode of onset acute anterior poliomyelitis bears the impress of an infectious origin. The recognition of its seasonal relations has served to confirm the view of such an origin. The occurrence of epidemics has rendered its causation by infection indubitable, notwithstanding our present ignorance of the real *materia peccans*.

The following is a brief summary of epidemics of which I have been able to find records: Colmer[1] relates that while on a visit to the parish of West Feliciana, La., in the fall of 1841, he saw a child about a year old which had been seized with hemiplegia, and he adds that he was informed on good authority that eight or ten other cases of hemiplegia or paraplegia had occurred during the preceding three or four months within a radius of a few miles. Bergenholtz (mentioned by Marie) observed thirteen cases at Umea in 1881. Cordier[2] reported thirteen cases of poliomyelitis which occurred during the months of June and July, 1885, among a population of 1500. Nothing similar had been known there in previous years.

Oxholm and others, according to Leegard,[3] saw nine cases between the end of July and the beginning of September, 1886, at Mandal in Norway. Leegard himself knew of several instances of two persons in the same household being attacked in quick succession. Medin[4] witnessed an epidemic of 43 cases in Stockholm in 1887, and another of 21 cases in 1895. From 1888 to 1894 there had been 29 sporadic cases. Both epidemics occurred in the late summer and early autumn.

The most extensive epidemic on record is that which occurred in Vermont, and lasted from late in June, 1894, into the fall of that year, culminating in August.[5] The scene of this epidemic was an area of 15 miles in length and 12 in breadth, with Rutland as a center. Caverly noted 132 cases which, he estimates, represented at least ninety per cent. of the whole number. In four families there was more than one case. Horses, dogs, and fowls were also affected. Altmann[6] reported fourteen cases of acute paralysis in children (nearly all of them, it seems, poliomyelitis, one hemiplegia) which occurred in the district of Port Lincoln, South Australia, during the months of March and April, 1895. The last case before the series was an isolated one in 1887, and no cases had occurred since. The proportion of the cases to the population amounted to 1 in 108. In two instances two members of the same family were attacked in rapid succession.

Buccelli's account of an epidemic[1] relates to seventeen children, all of whom dwelt in the same purlieu of Genoa. Of these twelve had atrophic spinal paralysis, and five spastic cerebral paralysis; all of them were taken ill between the last days of May and the middle of September, 1895. Buccelli refers to a little epidemic observed by André at Toulouse, in which a relation between the cerebral and the spinal form of children's paralysis was also evinced, and to other Italian epidemics besides that of Genoa; thus, one at Montespertoli was reported by Pieraccini, another by Cervesato at Padua, where twenty-six cases developed within five months, and Luciani stated that at Areuzano in June, 1883, there had been five cases within barely twenty days, after which, although the disease was common in his district, no accumulation of cases occurred within a short time until 1895, when three persons were successively affected at intervals of twenty days.

Finally, an instance of an epidemic limited to one household has been reported by Pasteur:[2] Seven children became ill in rapid succession within the space of three weeks with moderate fever and severe headache; within seven days of the onset one exhibited flaccid paralysis of the left arm, another cerebral spastic hemiplegia, and a third a spastic monoplegia, while two more escaped with tremors lasting a few days after the fever, and the remaining two had no nervous disturbance after the fever subsided.

The following facts may be gathered from the histories of these epidemics. The infection does not invariably produce a permanent or even a temporary paralysis. The brain (and the nerves) may be affected without implication of the cord, although less frequently than the cord, and those cases in which one child of a family suffered from a spinal and another from a cerebral lesion are not to be regarded, as has been done, as mere coincidences. A large majority of cases of acute poliomyelitis occur (in the Northern Hemisphere) between May and October, and the single epidemic reported from the Southern Hemisphere indicates a similar relation to season. Moreover, observing the dates of onset in 139 cases of acute poliomyelitis, and in 105 cases of acute "encephalitis" in children as registered on a chart by Buccelli, we see that the lines denoting increase and decrease of frequency of the two diseases are almost parallel, crossing each other only from March to April and in October. In the account of the Australian epidemic it is stated that the season was hot and dry; during the prevalence of the disease in Vermont the rain-fall was considerably below the average, and I may add that in California where there is practically no rain in summer, during the winter of 1888–1889 the rain-fall was disastrously scanty. But as the drought prevailed throughout the greater part of the State, and the epidemic was very limited in range, even if climatic conditions be credited with some influence, there must have been some additional factor which produced the disease within such narrow confines.

As to the guilty germ, for a germ may be justifiably assumed to be the immediate cause of the malady, there seems to have been no investigations yet beyond that of Schultze,[1] who found the diplococcus of Weichselbaum-Jaeger in the fluid obtained by lumbar puncture from a boy of five years with acute poliomyelitis. The malady sometimes follows in the wake of measles and other infectious diseases, as does also cerebral palsy in children, and future research will have to decide whether one and the same organism may produce the original disease and its sequel, or whether there there is a succession of different infections. Moritz Meyer[2] saw two brothers, adults, thus affected after measles, and Strümpell observed a boy who lived near a village in which three cases of poliomyelitis occurred in a single month, who was seized with encephalitis after measles.

HYSTERECTOMY FOR PUERPERAL SEPSIS; WITH REPORT OF A CASE.[3]

By J. RIDDLE GOFFE, M.D.,
OF NEW YORK;
PROFESSOR OF GYNECOLOGY IN THE NEW YORK POLYCLINIC; VISITING GYNECOLOGIST TO THE CITY HOSPITAL.

SURGERY is rapidly settling many vexed and complicated questions. It has invaded the realm of its sister science Medicine and taken to itself for its particular treatment certain diseases which were formerly considered the exclusive property of medicine. In some of these incursions into the field of medicine, however, it has recognized its limitations and has hastened to restore to its original proprietorship the fruitless object of its ambition. Among these epilepsy may be mentioned as a striking example. There are still some questions, however, which belong to the field of exploration in which the proper place of surgery has not yet been defined. Prominent among these is the serious question of determining the proper place or even, if you will, the propriety of hysterectomy in cases of puerperal sepsis. In spite of all the advances which have been made in the

intimate knowledge of this disease, I know of no human affection in which the attending physician feels more helpless than in the presence of a well-developed case of puerperal septicemia; not because of the lack of things to do, but because of the fear of the utter futility of any and all measures. The uncertainty of the exact pathologic condition and consequently the very questionable prognosis, whatever form of treatment may be adopted, when in attendance upon an act which should be and normally is a physiologic process, are sufficient at times to paralyze the judgment of the wisest counselor. When to stay one's hand and when to adopt the most radical measures are questions so incapable of solution upon broad general principles that even at the present day each case must be judged almost exclusively upon its own individual signs and symptoms.

The history of every case subjected to a definite line of treatment adds its quota of facts to the sum total of observations upon which broad principles may be based and definite lines of treatment assigned to their proper sphere. It is, therefore, with the hope of adding the detailed account of my experience in one case to the solution of the subject of my paper, viz., "Hysterectomy in Cases of Puerperal Sepsis," that I ask your attention to the following history:

Mrs. Mary W., aged thirty-five years, an Englishwoman by birth, and a housewife by occupation, was admitted to my service at the Polyclinic Hospital February 28, 1898. She had been married eighteen years and had given birth to nine children. There had been no particular difficulty at any of her confinements until the last which had occurred five weeks before the date of entrance. She stated that her last confinement had been pronounced a difficult labor, the child having presented by the breech; that she had suffered from hemorrhage previous to the birth of the child which was stillborn, and had had more or less bloody discharge continuously since that time. This had occasionally been characterized by the presence of large black clots of blood. She had suffered from cramp-like pains in the lower part of the abdomen, and from severe rigors, sweats, and fever which began on the third day after delivery. She said that her treatment had consisted of poultices, vaginal douches, and morphin. My clinical assistant who sent her to me, said that he had been called to the case the day previous and had found the patient sitting in a rocking-chair complaining of headache and feeling sick. Her temperature was found to be 103½° F., pulse 120. After learning the history of the case and making a vaginal examination he diagnosed puerperal sepsis and sent her to the hospital. She was immediately treated to a brisk cathartic which reduced her temperature and improved her condition generally.

Upon examination March 2d, a foul-smelling discharge was seen to be escaping from the uterus. The abdomen was distended and painful to the touch. The patient had been sent to the hospital for the avowed purpose of being curetted only, and without any previous conversation as to any further operative procedure she was placed under an anesthetic. The cervix of the uterus was patulous, edematous, and boggy, the fundus as large as a pregnant uterus at three months, and firmly fixed in the pelvis by an inflammatory, boggy mass reaching off to the right iliac fossa. Her temperature at this time was 101.8° F., the pulse 100, and the respirations 20. Under the circumstances no radical operation was permissible. The uterus, however, was explored with a sharp curette, some small fragments of necrotic tissue removed, and the uterine cavity thoroughly douched with 1 to 3000 bichlorid-of-mercury solution and packed with iodoform gauze. A diagnosis of metritis with probable abscess in the right broad ligament was made and the patient put to bed to await recovery from the anesthetic that the situation might be explained to her. She readily consented to a radical procedure and on March 5th, under anesthesia, she was subjected to an abdominal hysterectomy. The uterus was in an anteverted position but had settled low in the pelvis and coils of intestine and parts of the omentum were adherent to its surface; projecting from the right horn was a large mass made up of adhesions of intestines and omentum, and when this had been removed there appeared an enlarged and diseased ovary and tube closely adherent and surrounded by lymph. Catgut ligatures were used to control the hemorrhage; the uterus and broad ligament of both sides were removed *en masse;* the pelvic cavity was flushed out with a gallon of salt solution poured in through the abdominal wound and allowed to escape *per vaginam.* The pelvis was then packed with gauze, the end protruding through the vulva, and the abdominal wound closed with through-and-through silver-wire sutures.

Upon examining the specimen it was found that the walls of the uterus were permeated with accumulations of pus varying in size from that of a pea to a large one near the fundus fully an inch in diameter. The ovary and tube of the right side contained pus amounting in all to two ounces; those of the left side were similarly involved though not to the same degree. The patient rallied from the operation and her temperature gradually fell from 102.2° to 100°F. Her general condition improved to the extent that she was able to take more nourishment, but her temperature fluctuated from 100 to 103° F., with a tendency however, gradually downward until the eighteenth day after the operation when it reached normal. Upon the day following this, the nineteenth, a slight chill occurred in the morning and her temperature rose to 105° F. It as rapidly dropped to the neighborhood of 100° on the following day and then for a week it fluctuated between 99.5° and 102°, when it suddenly jumped again to 104° and 104.2° F. Thereafter the excursions in temperature were sudden and extreme, going every day from 99.2 to 105° and even

106° F. up to April 10th, thirty-six days after the operation, when, in spite of the most careful nursing, nourishment, and stimulation, she gradually sank and died from exhaustion.

On the nineteenth day when the temperature first made its extreme rise, there were signs of lobular pneumonia in the lower lobe of the left lung posteriorly, which was considered septic in its nature. This gradually disappeared, however, and the patient gave no signs of localized disease in any part of her body.

In the face of such a history the question is constantly presenting itself: Was the fatal result due to the delay in the capital operation—in other words, might she have been saved by a more timely radical interference? and, on the other hand, what measures, if any, might have been applied to prevent the case reaching the condition where radical procedure was necessary?

This brings up the whole subject of the pathology and treatment of puerperal sepsis. Without going into the details of the subject, perhaps the principal features can be briefly presented in a few axiomatic statements. It seems now very generally accepted that the vagina and uterus in women are normally aseptic. Pathogenic germs do not exist normally in the vagina, as the acid secretion is an efficient germicide. It may be confidently affirmed, therefore, that as a rule puerperal sepsis is caused by the introduction into the genital tract of specific organisms, whose multiplication and absorption, together with the ptomains and leucomains produced by them in the blood of the patient, produce the symptom complex known as puerperal fever.

We recognize two forms of puerperal sepsis—*sapremia* and *septicemia*. The former is the result of the absorption of toxins or ptomains secreted by germs growing upon a putrefactive focus. These toxins are the product of the less virulent form of bacteria, the progress of the disease, however, being dependent more or less upon the resistance of the patient. In some, the bacteria of suppuration grow luxuriantly, and abscess formation and pyemia promptly follow. Septicemia, on the other hand, is produced by the more virulent species, namely, the streptococcus. This form of bacterium does not need a suppurating focus, but finds its habitat on any lesion in the continuity of the tissues, in which it multiplies and secretes its ptomains. The German pathologist Bumm has found that under favorable conditions an inflammatory exudate forms about the seat of invasion, and aided by the phagocytic action of the white corpuscles, prevents penetration of bacteria to adjacent tissues. The inflammatory changes are confined by this circumscribed wall, and the process is limited to the enclosed area. In more severe infection or with less resisting power of the tissues, the bacteria break down the protective zone, penetrate the deeper structures, and enter the lymphatics and veins, by which not only the toxins but the micro-organisms themselves are disseminated throughout the entire system.

It becomes necessary, therefore, to recognize early in the course of the disease the character of the invasion, for the treatment varies with it. If the infection is saprophytic, the conclusion is that there must be some retained placental or necrotic tissue which demands removal. These cases are characterized by a chill and sharp rise of temperature early in their history, and by an offensive lochial discharge. Such patients, therefore, should be promptly subjected to curettage, and a thorough application of an antiseptic douche. If, on the other hand, the infection is that of the pure streptococcus, the nature of the treatment must be such as to assist the resisting power of the uterus, and so reinforce the phagocytic fight which is being made against the invasion of the bacteria. If this can be effectually accomplished and the resisting zone of tissue maintained intact, the streptococci die and the disease is terminated. If, on the other hand, in a case of great severity in which the streptococci break down the resisting zone and gain entrance to the lymph and blood-currents, general infection occurs and the patient usually dies. Sustaining treatment, however, is indicated, and the prognosis depends upon the ability to maintain the vitality of the patient until the invasion shall have run its course. In pure streptococcic infection the curette has no place. It would simply break down the resisting zone and open the way for ready entrance of the bacteria, and in the more serious cases it cannot possibly do any good at the period of recognition of the disease, for the invasion has already passed beyond its reach. Mixed infection sometimes occurs. The saprophytic and streptococcic infection occur simultaneously, and these may be still further complicated by the presence of the gonococcus, the colon bacillus, and a horde of less familiar micro-organisms. Under such circumstances the wise course seems to be to control the saprophytic action by removing promptly any and all necrotic tissue which may be found in the genital tract, thus stopping the absorption of ptomains, and at the same time fighting the streptococcic infection by careful nourishment and stimulation. If, in spite of vigorous treatment along both of these lines, the patient goes steadily from bad to worse, or the convalescence is delayed, the question then arises, What more can be done? There is no doubt, as shown in the case just reported, that the walls of the uterus do become

permeated with pus to a degree that renders it impossible of disinfection, and the only hope of saving the woman's life lies in the radical removal of the organ. Experience has shown, however, that to decide just when the invasion has passed beyond the reach of the curette but is still retained within the confines of the uterus, is a simple impossibility. The more conservative clinicians maintain that in sapremic infection all that can be accomplished by operation lies within the reach of the curette; while in streptococcic infection the moment the resisting zone is broken through, either by artificial interference or by the aggressive work of the bacteria, the lymph streams are invaded, and the case is beyond the reach of local procedure.

To come out of the region of theory and generalization, my method of practically handling a case of puerperal sepsis is as follows: A chill and rise of temperature in a puerperal woman are never condoned by me as a probable milk-fever or a malarial attack. If a parturient patient has a chill, however slight, with rise of temperature to 100° F. or above, attended by a malodorous discharge from the vagina, my rule is, if no other well-defined disease is apparent, to at once place her upon a table, examine minutely the whole genital canal and pelvis, and explore carefully and thoroughly the entire endometrium with a sharp curette. This can usually be done without an anesthetic, the patient lying upon her back, and a posterior self-retaining retractor being used to expose the parts. The anterior lip of the cervix is then seized with a pair of volsellum forceps and drawn down until the uterus is steady. This opens the cervical canal and offers free access to the uterine cavity, as well as permits free drainage therefrom. Any piece of retained membrane or placenta is carefully removed, the endometrium thoroughly flushed with bichlorid, 1–3000, and afterward carefully washed with a normal salt solution, and the interior of the uterus thoroughly packed with iodoform gauze. Any raw surface of the cervix or vagina is touched with pure carbolic acid, and the vagina packed with a strip of iodoform gauze. The moment the indications for this treatment arise, I allow as little time as possible to elapse before it is put into execution. In my hands it has been uniformly successful, and I have never lost one of my own patients from puerperal sepsis, although I have had a number of cases in which there has been an undoubted infection, the symptoms first appearing on the third, fourth, or even as late as the sixth day.

It is rare to see cases in consultation as promptly as can be done in one's own practice, but in puerperal cases in which a chill and a rise of temperature with a malodorous vaginal discharge or a suppression of lochia, together with a suppression of milk, at any time from the third to the tenth day after confinement has occurred, I invariably advise a careful exploration of the entire genital tract, exploring the uterus with a sharp curette, douching it with antiseptics, and when indicated packing with iodoform gauze. The gauze is left twenty-four hours, and if the progress of the case is favorable, sometimes forty-eight hours. It is then removed, and vaginal boracic-acid douches are given daily, or the douches may be omitted entirely, and the vulva simply covered with an aseptic pad. In the meantime, free drainage of the lymph vessels and spaces is maintained by the open-bowel treatment, and the most stimulating nourishment and sustaining treatment is applied. Great reliance is especially placed upon the use of alcoholics, together with strychnin, strophanthus, and small doses of quinin, as may be indicated. Rarely is it necessary to repeat the local treatment, but in a few instances it has been resorted to with benefit. These cases have been characterized by an extreme amount of necrotic tissue at the time of the first curettage, and a continuation of the offensive lochia. If the symptoms are not arrested by this treatment, if there are signs of constant infection as indicated by a steady rise of temperature, a languid indifference and hebetude, sensitiveness over the uterus and broad ligaments, or chills with rise of temperature, the question of radical interference in the way of exploratory laparotomy suggests itself. My inclination, however, is to refrain from any such procedure unless I have very positive evidence of the presence of pus. Under these circumstances an operation is indicated, provided the general condition will justify it, and the extent of the procedure depends upon the condition found.

In the case above reported, the multiplicity and size of the pus collections in the walls of the uterus indicate that this process was in progress previous to the invasion of the appendages. This finds confirmation clinically in the prolonged constitutional resistance to the disease previous to the operative procedure. The probabilities are, therefore, that this patient's life might in all probability have been saved by an earlier resort to hysterectomy.

New Military Hospital at San Francisco.— Colonel Marshall, Chief Quartermaster at San Francisco, has received authority to expend $113.339.50 on the new pavilion hospital to be erected at the Presidio of San Francisco. This is about double the original appropriation, and provides for a much larger and better-built hospital than was at first contemplated, although the number of beds remains fixed at 400. Work will be begun on it as soon as possible, and it will be completed in six months.

SPECIAL ARTICLE.

THE MEDICAL NEWS' INVESTIGATION INTO THE CLAIMS OF CHRISTIAN SCIENCE.

By JOHN B. HUBER, M.D.,
OF NEW YORK;
ASSISTANT TO THE CHAIR OF PRINCIPLES AND PRACTICE OF MEDICINE IN THE NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.

(Continued from page 78.)

I COME now to the presentation of the cases I have investigated. To every Christian Scientist who had the kindness to refer to me cases for investigation I stated that I did not wish to examine nervous manifestions of a hysterical sort, or purely functional disorders. I wished to see cases of disease in which the structure of the organs was likely to be or to have been involved. Having explained this to begin with as clearly as I could I took the subject's history and ascertained whenever possible the name of any physician who may have acted before he or she went "into Christian Science." Almost all of these physicians who live in New York I have visited; to the others residing here and to those who live out of town I have written, the form of the letter being generally as follows:

"DEAR DOCTOR: I am investigating Christian Science from the physicians' viewpoint, and am examining a number of people in the hope of presenting some twenty histories. These histories would, I think, be valuable only in so far as they would be scientifically accurate. Therefore, whenever possible, I request a medical account from any physician who may formerly have been in attendence. I have now under observation the case of Mr. X., who believes himself to have been cured 'in Christian Science.' I would thank you very kindly if you would send me whatever medical information you can concerning this case, with records of examinations if possible. And will you please indicate whether or not you would wish your name to appear; in the latter event it will not be published. The cases will be numbered, not named."

I have recorded my own observations of the subject's condition at the time of my visit. Comments not immediately relevant I have put in brackets at the end of the history. I have numbered the cases nearly in the order of the time of my seeing them. R. refers to regular, H. to homeopathic, and E. to eclectic physician.

CASE I.—An unmarried woman, thirty-eight years old. Father died at the age of sixty-eight of cancer of the stomach. Was born prematurely at seven months. Her mother fell from a chair to the floor and her birth resulted several hours afterward. From birth up to the spring of 1898 she never had the use of her feet except that she could progress on the tips of her toes by using crutches. Her arms were rigid and immovable; her legs were extended and could not be flexed; her lower extremities could not be separated, so that from the friction between the thighs there resulted an inflammation which required the constant application of zinc ointment. Until the spring of 1898 her back across the spine was a plain surface, the usual depressions about the spinal column being absent. The shoulders were raised and the head depressed between them; the chest and the chin were much nearer than in a normal condition. Up to this time she could not raise her feet and could not sit up. Under her arm, because of the use of a crutch, there had developed a tumor two inches in diameter. Was helpless in bed; could not turn around; could not move head or foot; "stomach was bulging." Attendants had to stand on the bed and move her about like a sack of salt. Until her tenth year she crept about; then she used wheel crutches until the age of sixteen. For two years during her early childhood she wore a "harness" and iron braces from her tenth to fifteenth year; from fifteen to twenty-one many other appliances were tried. She had shoulder-braces, which were strapped tight and "nearly broke her back." She wore at one time padded-iron braces down her back, applied along both sides of the spine, with braces across the shoulders and the lumbar region and down to her knees and fastened in front by belts. It was said that "her brain was too large at birth—a man's size." During childhood she had had a number of ailments—heart and kidney trouble, rheumatism, diphtheria, scarlet fever, dropsy, whooping-cough, jaundice, and involuntary flow of urine. As a child she was very nervous. Her speech was impaired. From childhood up to the spring of 1898 she suffered at various times from dyspepsia, kidney trouble, a tinge of diabetes, dropsy with swelled feet, hot flashes, chilly sensations, mist before her eyes, headaches, flatulence, heart would get weak and she would swoon, irregular courses—sometimes very free and at other times absent. She had great pain at times, was often irritable and despondent, and in 1895 and at other times had attacks of nervous prostration.

In March, 1898, while in Philadelphia she tried "mind cure." At first she got better even under the mind cure, but later she got worse. She says, "I met a number of people (among the "mind curers") who seemed to me queer; their actions were funny and I felt as if I were associating with people beneath me. They had no church, no Christ, and I wanted to get away from them. I tried to get away but they seemed to hold me in Philadelphia, and I couldn't tell why I stayed there. Their thought held me. Finally I made the excuse that I wanted to take a trip to Atlantic City and while there should take from them 'absent' treatment."

She went to Atlantic City, where she met the woman whose history is detailed under Case II., who influenced her to take up Christian Science. She has been in Christian Science since May, 1898; she now feels better but is not wholly well. She can now separate her knees and can sit up, can raise herself, and can now with assistance walk up steps. She has decreased about four inches in size at the waist.

Up to her twenty-first year Dr. A. (R.) was her family physician; she was also at various times seen by Dr. B. (H.), Dr. C. (H.), Dr. D. (H.) and Dr. E. (H.). Dr. A. writes that fifteen years ago he destroyed the records of all his cases up to that date; the following account is therefore from recollection. "When and at what time the paraplegia of her lower extremities was first noticed I do not remember, but I know that it was at a

very early age; do not know about the knee-jerk at that time; her mental functions were not impaired; no sensory disturbance present; pulse and temperature regular; appetite good; no difficulty in urination or defecation. Cold baths, mineral baths, animal baths, alcoholic lotions, and electricity were resorted to in the course of treatment without avail; internally chinin, iron, strychnin, etc., were given. After some time her father took her to Europe, consulting among others Professor F., and brought her home without being improved. Lost sight of her for a time; she went to Pennsylvania; did not see her again until last winter when she was carried by two servants from and to her carriage. What treatment if any, she had during this length of time I never heard."

Concerning the family history, her father and mother were healthy, there being no tuberculous or specific disease on either side. Her mother died from eclampsia after confinement more than thirty years ago; her father from cancer of the stomach. One brother, two half-brothers and two half-sisters are living and healthy.

This subject is below the average height, but the lines of the normal female figure are to a large extent obliterated. She is able to move her arms and to partly flex her legs. She sits in a chair, but more backward than ordinarily. Her movements are awkward. Aided by her maid, with what seemed to me considerable difficulty, she arose from her chair. Her heels were planted upon the floor. The maid being on one side and I on the other, she was able to walk across the room and back to her seat, progressing about six inches with every step. She leaned upon my arm rather heavily; possibly she leaned upon the maid still more so. She is thick of speech and her mental coordination seems rather slow. She appears otherwise to be in good health. [A very estimable woman.]

CASE II.—A woman, aged forty-six years; married at the age of thirty-one years. Eyes troubled her as a child. This trouble continued until she left school (after her sixteenth year). When about twenty years old an ophthalmologist (Dr. A.) pronounced her trouble "hereditary astigmatism, an organic malformation, not the result of any disease of childhood. Eyes were born wrong. If she had worn glasses at six she would not have had any trouble." The glasses prescribed were worn, with but slight temporary relief. This distress and pain continued about eight years. During this period she had nausea, vomiting, and pain over the eyes and in the eyeballs. Besides Dr. A., she saw Dr. B. and Dr. C. (H., now deceased). She then saw Dr. D. (R., deceased), who treated her several times for granulated lids. A year after she saw Dr. D. again. On this second visit he made a very thorough examination, and then put her case into the hands of Dr. E., his assistant. Dr. E. decided to change glasses, which was done. She was then to use Dr. E.'s prescription for reading and sewing, and the old glasses prescribed by Dr. A. for distant sight. After using Dr. E.'s glasses (made by a New York optician) a few weeks, her condition became such that she could not read, and when she walked it seemed as if the ground were receding, and again, as if she were going upstairs.

Such was the state of things until about February, 1888, when Christian Science came to her. She had become nervously run down because of the compulsory idleness and the fear of being considered stupid through lack of reading, etc. Up to this time she had read but one book, a volume of Prescott's "History of Peru." At first a Christian Scientist assured her that the pain could be relieved. Then the Christian Scientist asked her to take the book "Science and Health," and to read it. This she decided to do, and read the book through in one week, using her old glasses (not those prescribed by Dr. E.). The first evening she read seventy-five pages, and was amazed to find that she was afterward unaffected, whereas her former experience (before going into Christian Science) was that she would have headache, nausea, vomiting, etc. The day after reading these seventy-five pages she awoke feeling good, and she went on thus for a week, getting better and better. During the month following (although she wore glasses) she was perfectly free from pain. She felt exhilarated. Then the thought came to leave off wearing glasses, which she did. The first morning after discarding them she could not see; she was as before, and had nausea, vomiting, headache, etc. These symptoms continued three weeks. This was a "chemicalization." Nevertheless, she was determined to do without glasses, and continued for three weeks without their use. She knew it was not the glasses or the disuse of them which produced these symptoms. During these three weeks she read a sentence every day without using glasses, and the effort was accompanied by all the old suffering. At the end of three weeks (in April, 1888) she awoke one morning perfectly free from pain, and since then has not used glasses and has not had a return of the old symptoms. She believes the use of the glasses was not necessary, and that the "truth" which healed the trouble when the glasses were used, would heal the trouble as well with the glasses off.

Dr. A. writes that his record of this case, taken about twenty years ago, has been destroyed, but he recalls that she had "hyperopic astigmatism," which he thinks was corrected with glasses. He knew the subject in her youth as a woman in every way worthy of confidence. Dr. E. writes: "November 23, 1885. Mrs. X., aged thirty-three years. After a few moments of reading there is a strained feeling which is followed by nausea. There is also almost always pain. Cannot read ten minutes without pain. For seven years the trouble has been decided. Previously to that for several years she had worn colored glasses on the street on account of sensitive eyes. Had defective vision at school and thought she was nearsighted before the age of twenty-three. Used eyes freely at night during school-life.

R. V. $= \frac{20}{60} : \frac{20}{30}$ with $- \frac{1}{12}$ s. $\bigcirc - \frac{1}{60}$ c. ax. 180°.

L. V. $= \frac{20}{60} : \frac{20}{30}$ with $- \frac{1}{10}$ s. $\bigcirc - \frac{1}{50}$ c. ax. 180°.

November 24, 1885. Under atropin.

R. V. $= \frac{20}{80} : \frac{20}{30}$ with $+ \frac{1}{36}$ c. ax. 90°.

L. V. $= \frac{20}{100} : \frac{20}{30}$ with $+ \frac{1}{12}$ s. $\bigcirc + \frac{1}{36}$ c. ax. 90°.

November 15, 1885.

R. V. $= \frac{2}{20}$ with $+ \frac{1}{12}$ s. ⌒ $+ \frac{1}{30}$ c. ax. 100°.
L. V. $= \frac{2}{20}$ with $+ \frac{1}{12}$ s. ⌒ $+ \frac{1}{30}$ c. ax. 80°.

December 14, 1885. Ordered the last above.

November 8, 1886. Eyes better. Glasses helped her for some time, but now eyes pain and cannot use them more than half an hour sewing or more than ten minutes for reading. No glass better than her own.

November 11, 1886. Adduction 13°, abduction 5°.
Ordered for near rt. $+ \frac{1}{42}$ s. ⌒ $+ \frac{1}{30}$ c. ax. 100°.
lft. $+ \frac{1}{42}$ s. ⌒ $+ \frac{1}{30}$ c. ax. 80°.

Of course it is possible for a person young and possessed of his accommodation, with such an error of refraction as the above, to use his eyes without glasses. As to whether the person experiences pain in doing so we have to rely upon his evidence.

At her present age, forty-six, the lady probably does very little reading without glasses, as presbyopia is beginning to come on along with her "compound hypermetropic astigmatism."

I opened, at random, a Bible printed in easily readable type and asked the subject to read. She read without glasses some twenty lines and then wished to stop. It seemed to me she found the reading fatiguing. She refused to have her eyes reexamined.

[This subject seems exceedingly conscientious; to be afflicted, in fact, with a sort of moral hyperesthesia. "Chemicalization" is a figurative term referring to what seems to occur frequently in Christian Science. The patient, shortly after treatment is begun, becomes much worse, soon after which he becomes better and better. This is explained somewhat as follows: The "acid" influence exerted by the healer acts upon "alkaline" error (the disease); a precipitation occurs, above which appears the pure, clear fluid "truth," as exemplified in Christian Science.]

CASE III.—Widow, aged sixty years. Father died of consumption. Had weak lungs from childhood. Had womb trouble with convulsions from time to time from her eleventh year. At the age of nineteen had pneumonia. As long as she could remember has had a fall and winter cough. Being troubled with uterine cramps, diminished flow and clotting, she went to the sanatorium of Dr. Thomas Addis Emmet in New York during the winter of 1868–69. Married in 1872. Menses still painful and irregular. Son born in 1873. Then had partial paralysis on right side for three years; up to the year 1875 she had to be lifted in and out of her carriage. In 1879 had pneumonia while living in Brooklyn (would not give physician's name). From 1879 to 1883 she was in delicate health. In 1885 she had pneumonia again, being treated by Dr. C. (R., now deceased). She had yellow fever at one time while at New Orleans. In 1890 had the grip. Treated by Dr. D. Her heart at this time was very weak. In 1891 she fell in a boat upon the end of her spine. She was in great agony and suffered what she understood from her physician to be coccygodynia. She had sensitive spots in the small of her back.

She was in this condition from the fall of 1891 to December 22, 1893, suffering practically all the time. Up to her fortieth year she had had good eyesight; at that time astigmatism was discovered and then for fifteen years she wore glasses. She had different glasses prescribed by Dr. E., for reading and for distance; she also wore stained glasses. Her weakened condition resulting from grip took her to the sanatorium of Dr. F. Here "the brain of an ox, the stomach of a pig, the liver of a fish, and dead flies (Spanish) were her gods"; these substances were given by hypodermatic injection or by the mouth. She had also electricity, baths, and massage. During this period she had attacks of nervous prostration and from time to time had cataleptic spells.

In October, 1893, she came upon the book "Science and Health." In spite of the doctor's admonition not to use her eyes she began reading it. It helped her eyes and her spine. Her back was a little better after beginning to read. Then she gradually improved. At first she used two pair of glasses, reading only a paragraph at a time. The thought came to her that God did not send the sickness. Then came "the light" that God could be her strength. She had been an Episcopalian, and had a son studying for the ministry. After reading fifty pages "it came to me that if God is my strength, I should get out of bed. Why do I lie here? Don't mind if back is worse. Then I got up and walked a few steps." Since then she has been able to walk. About three weeks after beginning to read "Science and Health" she walked out of doors. She left the sanatorium December 22, 1893. Had not taken medicine by the mouth for a month before she left, but until her departure she took electricity, baths, massage, and hypodermatic injections. Then she went to Washington, D.C., arranging to return if she did not feel well in two weeks. She states that no medicines have been taken for five years past. She held firm to the thought that God is love; she did not fear and therefore she did not become sick. At one time she had cramps ten consecutive nights; she would fight by "Science," and in half an hour the attack would disappear. She also had urticaria with these attacks of colic; "big welts" came upon her; this was also treated by "Science." She had "belief" in pain in head and eyes from December, 1893, until the summer of 1895. She then determined not to use glasses, and has not used them since. Can now read without difficulty. In January, 1898, had "pneumonia" for the fourth time. States in answer to questions, without which she found it difficult to recall symptoms, that she had fever (no thermometer used, but she felt hot), was short of breath, had catch in side, had "congestion" in head, coughed frothy blood, had a dry mouth, thirst, and aching in limbs. No physician had made a diagnosis. With this "pneumonia" she walked in a snowstorm more than half a mile from the house to the church four different times for four treatments. During this illness she had feelings of exhaustion. Her heart beat fast from time to time. Once she fell over on the bed, but with an effort she got up, being determined not to lie down.

Dr. Emmet does not know anything about this woman and doubts if he ever saw her. On his books of about that time there is a record headed with the same initial as that of this woman's surname (Miss X), who may or

may not have been the same person. This record is of a case of anteflexed uterus.

Dr. D. writes: "In manner she was decidedly gushing, some thinking her insincere, others perfectly sincere. She entered actively into church and mission work, etc. She was enthusiastic in all things, and as I especially remember, an enthusiastically grateful patient. I treated her for grip. I am positively able to recall that my impression of her character was that while she was rather gushing and enthusiastic, she was sincere in so far as her peculiar nervous organization permitted, and that she was a person whose views and feelings might easily undergo a change. In fact, the type was a neurasthenic one, and I am not surprised that she has become a so-called Christian Scientist."

[This subject is a "healer," and treats others. She is excessively nervous. During the conversation while walking across the floor she illustrated in an exaggerated and theatrical manner how she got out of bed at the sanatorium in 1893, etc.

Dr. Emmet recalls the case of a woman with pelvic peritonitis who had been an invalid for years. She was brought from Honduras to his sanatorium, where she remained for one year. For eight months of this time she lay bedridden. Toward the end of the year she was cured. Then Dr. Emmet sent for her husband to come and take her home. In the meantime she lived at the sanatorium, going about the city in good health, shopping, play-going, etc. One day she entered a Christian-Science church; she claimed she was cured there in a few minutes. She then consulted a lawyer for the purpose of suing Dr. Emmet for the money which had been paid for his services.]

(To be continued.)

MEDICAL PROGRESS.

Ectopic Gestation Twice in One Patient.—Ross (*Amer. Jour. of Obstet.*, etc., December, 1898) reports an unusual and interesting case of a woman, aged 26 years, who, while nursing a baby seventeen-months old, developed a tubal pregnancy of the right side. The tube was removed, and although it had not ruptured there was a large amount of tarry blood in the abdominal cavity, which had leaked out of the fimbriated end of the tube, drop by drop. There was slight peritonitis following the operation, but recovery was perfect. Two years later the symptoms of extra-uterine pregnancy again appeared, and again the abdomen was opened, and the left tube containing a fetus between one and two-months old was removed. The patient recovered. This is the second time that Ross has had the unusual experience of operating twice upon the same patient for ectopic gestation.

State Regulation of Marriage.—Burr (*Jour. Amer. Med. Ass'n*, December 3, 1898) holds that the State should require every applicant for a marriage-license to present a certificate from a physician in proof of the fact that he is free from acute and latent gonorrhea and syphilis in a form to be communicated, as well as from tuberculosis and insanity. He maintains that the publicity thus attracted to latent gonorrhea would do much to acquaint the world at large with the evils to the innocent party which marriage often causes. Noeggerath and Ricord taught many years ago that the majority of males become gonorrheic usually before matrimony, and that ten to thirty per cent. of females become so usually after marriage. Such legislation would do more than anything else to bring this knowledge to the minds of those most concerned and would create a public sentiment against the male libertine which does not exist to-day. It would besides save the State an immense outlay for the support of idiotic, deformed, and insane children, and would be a long step in the direction of a condition in which the birthright of every child shall be good health. He presents a blank form of a bill to be passed by legislators to accomplish these objects.

Sensitiveness of the Cervix and the Vagina.—Calmann (*Centralbl. f. Gyn.*, November 12, 1898) has investigated the sensitiveness of the vagina and cervix with a view to determining the reliability of testimony of a woman as to the character of instruments passed into these organs. He finds that most women, whether they have borne children or not, are not able to differentiate between the passage of a catheter into the urethra and into the vagina, and that they cannot decide when water is drawn from the bladder through the catheter, unless the bladder is very full, or they hear the sound of the water. The sensitiveness of the vagina is so slight that most of the women tested were unable to determine at all when an examining finger touched the vaginal walls, provided the vulva was not disturbed by its passage. Sensation in the cervical canal is more acute than in the vagina, but most of the women could not say whether the instrument was in the vagina or in the uterus. Sensation during pregnancy is not more acute than at other times. Cold was often recognized, but heat of 40° C. (104° F.) was never noticed. Strong disinfectants, such as carbolic acid or bichlorid of mercury reduced the sensitiveness.

Voluntary Asexualisation.—McCassy (*Jour. Am. Med. Ass'n*, December 3, 1898) makes a suggestion in regard to the asexualisation of certain criminals, notably those who have been guilty of rape, that seems to do away with the objection which society has to depriving a man of his testicles, even when he has used them to destroy the happiness of his fellows. He proposes that criminals of this kind should be sentenced to prison with the understanding that at any time within a year, if they so desire, they might submit to castration and go free. As the imprisonment for such offenses is from five to twenty years he is of the opinion that few men would hesitate to accept freedom on these terms, and as they would be in a condition which would make a repetition of their offense impossible, there would be no reason for detaining them longer at the expense of society. An additional advantage to society would be found in the limitation of the offspring of criminals of this class.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

J. RIDDLE GOFFE, Ph.M., M.D., Editor,
No. 111 FIFTH AVENUE, NEW YORK.

Subscription Price, including postage in U. S. and Canada.

PER ANNUM IN ADVANCE	$4.00
SINGLE COPIES	.10
WITH THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, PER ANNUM	7.50

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

SATURDAY, JANUARY 28, 1899.

THE EXCHANGE SYSTEM AMONG JOURNALS.

IT has been the custom among all periodicals to carry out a friendly exchange week by week or month by month until at the present time the exchange-list of every prominent medical publication contains a very considerable number of journals, from which the editor gains valuable material if he desires to place before his readers in editorials or in abstracts a general idea of the progress of current medical literature. The perusal of these journals also keeps him in touch with the needs of his readers, and he is able to recognize the faults and advantages of his contemporaries so that his own pages are the well-rounded-out results of an intimate knowledge of contemporaneous editorial work.

Our attention has been called to this matter by the decision of one of our contemporaries to cease exchanging with all journals at the beginning of the present year, intending, it is said, to subscribe for those journals which it requires, in this way avoiding exchange with a number of periodicals which are useless to it. By the carrying out of this process of exclusion, it seems to us that a small expense is saved and a large loss accumulated, not only to the journal and its editorial staff, but also to those who may see fit to publish original articles in its pages, for not only will the editorial staff be limited in its field of vision in medical literature, but there are many articles of great value published from time to time in journals which ordinarily contain little of value, which will be overlooked; and furthermore, original articles appearing in our contemporary will not be abstracted in other journals and therefore the author of an article will only have the readers of the first periodical, whereas, had a number of journals abstracted his article, his name and work would have appeared before a very much larger proportion of the profession than one journal can possibly reach.

We have watched, during the last few weeks, the editorial comments which have been made by our contemporaries in regard to this plan and we have been struck with the unanimity with which they have prophesied the continuance of the exchange system among the remaining journals in the medical field, both upon the basis of fraternal feeling, commercial advantage, and editorial usefulness.

THE WORLD'S MEDICAL LITERATURE.

IN the Exchange Department of the MEDICAL NEWS are found the best medical journals of every part of America and Europe, as well as of India, Japan, and Australia. In all, 133 weekly and monthly publications were regularly searched last year that the best medical literature of the world might be placed in condensed form before the readers of the NEWS.

How best to present these abstracts has been the constant thought of those who have charge of this department. In journals which make a special feature of abstracts, it has sometimes been the custom to select a dozen or twenty of the best exchanges and give abstracts of their articles under their own names and dates. The systematic appearance of the pages appeals to one at first sight, but, in many instances, it is a great waste of space, as it compels the printing of many abstracts which would never be given were it not for the fact that the articles thus abstracted appeared in the chosen exchanges. Furthermore, by this plan many good articles are neglected because they appear in some paper whose general standard does not entitle it to be placed among those regularly abstracted in full.

The aim of the NEWS is rather to select from the

whole list of exchanges such articles as have an especial interest irrespective of the paper in which they are published. By this plan, in the year just passed some 313 abstracts were printed, taken from no less than ninety different papers. It is seldom that a single number of a medical paper contains more than two articles worth abstracting. Often there is only one. Whether many or few, it is our purpose and effort to give them in the briefest possible form consistent with clearness, and the physician who follows these pages from week to week will not only gain many valuable suggestions in the treatment of disease, but will be kept reasonably informed of the "Progress of Medicine." For the specialist there are special journals which chronicle the advances in his chosen subject. The columns of the "Exchange Department" belong to the general practitioner of medicine and surgery, and that which is printed in them the educated physician should not allow to escape him.

THE ORIGIN OF EPIDEMICS AND SOME ANALOGIES.

THE recent epidemic of contagious disease of the genus influenza which has been so widespread throughout the country has not only caused many cases of serious sickness but has been the occasion, through its complications, of many fatalities. In comparatively small towns and even in country places there have occurred cases that pointed to the presence of some special infective agent. Just where it came from and just what were the peculiar circumstances and conditions, meteorological and otherwise, that favored its growth at this particular time remains a mystery.

There are analogies to this as yet inexplicable phenomenon that are very curious and peculiarly interesting to the medical man because of the light they may shed upon the origin of epidemic disease.

A correspondent of *Science* reports the occurrence recently of swarms of strange butterflies, probably *anosia plexippus*, in the neighborhood of Topeka, Kan. There were so many of them that they prevented work out of doors, practically stopped all business for a time, and stopped railway trains by their presence in crushed, slippery masses upon the rails beneath the wheels. The correspondent recalls the occurrence of a similar swarm at Unadilla, Neb., in 1885. Whence they come and why they happen to arrive thus at unknown intervals in such unusual swarms is as yet unknown.

During September of last year dwellers along the shores of Providence Bay, Rhode Island, noticed that the water of a considerable portion of the bay became thick and red, emitting an almost intolerable odor. On the 9th and 10th of September thousands of dead fish, crabs, and shrimps were found strewn along the shores or even piled up in windrows. Only where the water had assumed a deep red color were the fish found dead, though for several days before this myriads of shrimps and blue crabs and vast numbers of eels, menhaden, and flat fish came up to the surface and to the edge of the shore as though struggling to get out of the noxious water.

It was commonly believed that dyestuffs or other refuse emptied into the rivers at the upper part of the bay gave to the water its color and unpleasant odor, but microscopic examination showed that the water was swarming with minute organisms, a species of *peridinium*. *Peridinium* is ranked, by some, among plants, by others among the animalculæ. It is reddish brown in color and occurring in such excessive abundance gave to the water its peculiar color and odor, besides making it so opaque that a white shell six inches below the surface could scarcely be recognized. The correspondent of *Science* who reports the fact thinks that the *peridinium* was the cause of the mortality among the inhabitants of the sea, an actual epidemic of microbial origin. The occurrence is extremely interesting and is important because here, as also in the case of the butterflies, the conditions of its origin are either simpler or are brought about by factors that may be easier to discover than the inscrutable origin of influenza. Let us hope, as seems not improbable, that the natural sciences thus working together will soon give us the key to this important problem.

QUININ IN MALARIA—A CONVERT.

THE *Journal of the American Medical Association* in the issue of November 12, 1898, said editorially:

We believe that great caution is necessary concerning the use of quinin particularly when the kidneys are involved. . . . No less an authority than Koch on his return from Africa asserted that the abuse of quinin in severe malarial infection of the

estivo-autumnal type is responsible for many of the complications seen in the malignant forms of malaria in that country. . . . The estivo-autumnal parasite most frequently produces nephritis, and is least affected by ordinary doses of quinin. In other words, that form of malarial infection which by its persistency would lead to the use of large quantities of quinin, also produces a condition of the kidney which makes the use of large doses of this drug of doubtful advantage.

We protested against the tone of this editorial and its implied discouragement of the free use of quinin in severe attacks of malaria especially of the estivo-autumnal type. We said that the writer of the article could be classed only with those who have had little or perhaps no experience with serious cases of this disease. Dr. Hare saw fit to answer our protest. It seemed clear to him that our ignorance of the question was most profound. His unasked for championship of the *Journal's* position in the matter was evidently unappreciated by those most interested, for we are glad to note that the editor of the *Journal* has realized that these editorial expressions are, as we said, calculated to do a great deal of harm. The issue for January 14th contains a complete and most satisfactory editorial recantation — "Quinin in Malarial Hemoglobinuria." We quote it:

The foremost physicians who practice in malarial districts are not afraid of quinin. If four grains of quinin every four hours will not break up a chill, ten and fifteen grains are given with impunity and without producing a hemoglobinuria, and if fifteen will not suffice in a case of pernicious fever thirty grains are frequently given hypodermatically. The toxin of malaria causes a hypertrophy of the spleen, will destroy the red blood-globules, will cause a chill and, being poisonous [to say that a toxin is poisonous smacks somewhat of tautology], may irritate the kidneys while quinin has *never been proven* to be the *etiologic factor* in *any* of *these conditions* [italics ours], and therefore must be the least causal agent in the production of a symptom for which it should be used.

LAMENTABLE INCONSISTENCY.

THE *New York Times* has, since the death while under the care of a so-called Christian Scientist, of its London correspondent, Mr. Harold Frederic, taken a most commendable interest in exposing this humiliating and disgusting modern device for exploiting and perverting the religious instinct. *Macte virtute!* the cause is one worthy of a great newspaper, and the *Times*, we are sure, has won golden opinions from thousands of sensible readers for its excellent work in this direction. It is to be regretted that other great journals do not realize the magnificent field there is in such matters for real benefit to their readers.

But now that we have said thus much in praise may we be permitted to call the attention of the *Times* to the fact that in its advertising department it is lending itself to "most humiliating and disgusting modern devices" for exploiting that other instinct which is quite as precious as the religious emotion, the feeling in humanity that makes for self preservation. Every day its columns contain advertisements of so-called proprietary remedies which would not require a seer in the editorial office to recognize as "disgusting devices" for taking advantage of the feeling that sends the poor invalid wherever there is held out to him the hope of relief. It is folly to say that these remedies and quacks are not known to be such. They are a good deal worse than the Christian Scientists because they reach a greater number of people and because a great newspaper knowingly and for pecuniary reasons lends itself to their service.

The *Times* said one day last week "As for newspapers, not a few of them, whether from cynical indifference or interested partiality we do not know, do not find it incompatible with decency to fill column after column with the blasphemies and imbecilities of the Scientists."

This is all very true, but in the meantime the *Times* seems to be very unconscious of a particularly large and conspicuous beam in its own eye. On the very day on which it published the expressions quoted above as to the position of other newspapers with regard to Christian Science, it gave in its columns what seems uncalled-for prominence to a report, two years old, of tuberculosis in the houses of certain wards of New York City, and permitted as a reading notice just above it the advertisement of a man calling himself a tuberculosis expert. This man may be what he professes, but his assumption of unethical, unprofessional methods in proclaiming himself, ought at least to arouse suspicion as to his claims in the matter. His advertisement was worded with reference to the *Times'* belated account of a two-years' old report. Was there collusion between the news and advertising editors? and are not even the

news columns of a respectable journal that claims to be the opposite of yellow not to be protected from the intrusion of these "humiliating and disgusting devices" for making money out of poor suffering humanity?

ECHOES AND NEWS.

St. Vincent's Hospital of New York.—This hospital began its work in 1849; it will shortly celebrate its golden jubilee. An addition, about to be completed and furnished, has cost $300,000.

A New Vice in Paris.—Medical men in Paris have discovered a new vice to add to the many to which Parisians are already addicted. It goes under the name of petrolism, and a man who is a petrolique is one who drinks petroleum. Although this form of vice has but recently been discovered, the habit has probably existed for some time.

New York Foundling Hospital.—At the last meeting of the Medical Board of the above institution the following new members were elected to the Board: Attending obstetrician and gynecologist, John Aspell, M.D.; attending physicians, L. Emmet Holt, M.D., and Rowland G. Freeman, M.D., successors to J. Lewis Smith and Joseph O'Dwyer, deceased.

"The Medical and Surgical Review of Reviews."—This is a new English monthly which the editor hopes will fill, for medical literature, the place that Mr. Stead's *Review of Reviews* does for ordinary current literature. Tne first numbers show a careful editing and a thoroughly practical selection and condensation of the medical articles of the month that speak favorably for its usefulness to the profession.

Acids in Refrigerated Beef.—Surgeon Major Daly has furnished to the War Investigating Commission a precipitate which, he testified, was secured from an extract of so-called refrigerated beef on the transport "Panama." This beef was supplied for consumption by our troops in the late war. The precipitate furnished was on January 20th submitted to a chemical examination by Major Daly and Professor Clarke in the Government laboratory of the Geological Survey, with the result that it was found to contain boric and salicylic acids.

The Medical Department of the Kentucky University.—The annual session of this university began on January 2, 1899, under most favorable auspices. The following gentlemen, formerly professors in the Kentucky School of Medicine, were elected to Chairs in the Kentucky University: Dr. J. B. Marvin, principles and practice of medicine and clinical medicine; Dr. J. M. Holloway, professor of surgery and clinical surgery; Dr. C. W. Kelly, professor of anatomy; Dr. S. E. Woody, professor of chemistry and diseases of children.

The Remains of Soldiers Who Fell in Cuba and Puerto Rico to Be Returned.—Quartermaster-General Ludington has completed the arrangements for bringing back the bodies of soldiers buried in Cuba and Puerto Rico. They will be brought North in metallic caskets early in February by Government transports. Duly authorized relatives or representatives of the families of deceased soldiers who wish the remains sent to their homes are requested to notify the Quartermaster-General at once of such desire, stating in full the name of the soldier.

A Venereal Veteran of Ye Olden Type.—At his morning clinic for skin and venereal diseases at the Charité, Professor Lesser recently introduced to the class a patient showing the following: Chancroid which had destroyed most of the prepuce, right inguinal suppurating bubo, gonorrhea, gummata of the skin, perforation of the hard palate. Among the many beautiful tattooed designs on the breast of the patient was the following device:

"Wer lieben will muss leiden,
Ohne leiden liebt mann nicht!"

New Quarantine Stations.—President McKinley has signed an order placing the quarantine stations of Cuba and Puerto Rico in charge of the United States Marine Hospital Service, and providing new health regulations to meet the requirements of the close relations of the United States with those Islands. Since the quarantine service thus provided for is for the protection of the islands of Cuba and Puerto Rico as well as for the protection of the United States against both, the expenses arising therefrom will be charged equally against the revenues of these islands and the epidemic fund of the United States Treasury, payments to be made out of the epidemic fund and reimbursements made thereto from the revenues of the two islands.

The Indigent Insane,—The problem how best to provide for the increasing number of the indigent insane is a pressing one in several States. Many ways have been suggested from that of centralization in large State institutions to that of county hospitals. In Minnesota preference is given to the colony system for extending the existing accomodations. This is advocated on the ground that it combines centralized management with decentralized care of those who need least care and at a minimum of initial outlay and per capita cost. On these farm-colonies the insane occupants are expected to be nearly or quite self supporting. Dairying will be the chief farming industry pursued, as milk is the leading article of diet in the hospitals, and as this ruminative occupation is regarded as particularly soothing for disordered minds.

A Neolithic Lady.—Professor Brinton of the University of Pennsylvania notes in a recent number of *Science*, the presentation at the meeting of German Naturalists and Physicians this fall, of the bust of a female whose skull and portions of whose skeleton had been exhumed from a neolithic grave in one of the caverns of South France. Some modern examples have shown that, with the bony frame-work to build on, the soft parts of the head and chest can be restored without risk of error. The bust of the neolithic lady thus restored represents her as rather good looking and with features undoubtedly of the white

race. Professor Kollman of Basel, who superintended the reconstruction insists on the fact that empires may crumble and states decay, but the essential features of each human race persists indefinitely and unchanged.

"Poisonous Frocks."—Under this caption a prominent New York contemporary in a recent number quotes from the *Wiener Medicinische Blätter*, and comments editorially upon the story of the dermatitis gangrenosa set up in the snow-shovellers of Birmingham, England, some time ago, by the presence of chlorid of zinc in their *overfrocks*. As the garments in question were plain, everyday English overcoats supplied by the municipal authorities of Birmingham to the workmen, their metamorphosis (a true degeneration) into *frocks* and *overfrocks* during the story's Rund-Reise in Germany is an amusing one. We wonder just what mental picture was called up to the *Journal's* readers by that rather unusual English word "overfrock." Anglo-Saxon medical stories like other emanations of Anglo-Saxon intellect, do not seem to be improved by being made over in Germany.

Kleptomania.—This unscientific term seems the only one that can appropriately be applied to many cases of theft by women which can hardly be explained if normal mentality be assumed for those guilty. These cases must surely interest the alienist. The last one reported in New York is that of a woman worth $175,000 who was arrested for a $2.75 theft. This woman, states a daily paper, "has everything that money can buy, and has always held a high social position." Or, is the peculiarity under consideration an inevitably inharmonious trait (necessarily inevitable in a world in which nothing is absolutely perfect) in an otherwise perfect sex? For example, it is said (although the writer has himself never come upon any such instance) that the best of women would hardly be likely to remind a forgetful street-car conductor that her fare had not been collected.

Practical Work for the Relief of Defective Sight and Hearing among Public-School Children.—According to the *Brooklyn Medical Journal* the suggestion made by the Committee on Public Health of the Medical Society of the County of Kings, that an examination should be made of the sight and hearing of the children attending the public schools of Brooklyn, has borne abundant and valuable fruit. During 1897-98 50,000 children were examined with the result of finding that nearly one-third had defective sight, hearing, or both. To supply spectacles to the poor a fund has been established under the fostering care of the Brooklyn Teacher's Association, which has shown its great interest in the movement by contributing $150 as a nucleus of the fund, and by undertaking to solicit funds from those interested. This fund is to be drawn upon only by requisition from a school principal, endorsed by a physician, who must certify to the worthiness of the case. It is estimated that $5000 will be needed.

Fees of Medical Experts May Be Inquired Into.—A medical expert, testifying in the New York Court on behalf of the plaintiff in a case for damages resulting from injuries received in a street-car accident, was on cross-examination asked what compensation he was to receive for his services in the case. The question was excluded, but on appeal the ruling thereupon was held to be erroneous, and the judgment, which had been for the plaintiff, was reversed. Justice Cullen, who delivered the opinion for the appellate justices, said: "It is not necessary to descant on the discrepancies in the evidence of expert witnesses, depending upon the side for or against which they are called, nor shall we deliver a homily upon such testimony. But, with the imperfections that are conceded to exist in expert testimony, we think that the plainest dictates of justice require that the opposing party should have every opportunity to inquire into the fairness and interest of the expert, as well as into his scientific skill and knowledge. Plainly, the size of a fee a witness is to receive for his testimony may, in the case of a weak character, bias his judgment, and the parties and the jury are entitled to know just what compensation an expert witness has received or is to receive."

Gangrenous Dermatitis from Poison in Clothing.—The English medical journals reported in their issues for December 3d, a very serious case of gangrenous dermatitis from poison in overcoats. The men employed by the city of Birmingham to clean the streets after the November snow-storm, which was severe in England as well as in this country, were provided by the City Council with overcoats. The drippings from these, especially from the sleeves and the lower borders produced large sloughs on the men's wrists and knees. Over sixty of the employees were affected. The external symptoms were large patches of sloughing skin, dark green in color, surrounded by a very inflamed edematous area. There was a good deal of heat and smarting about the inflamed patches and considerable adenitis of the nearest lymph-glands. Large quantities of chlorid of zinc, with which the cloth had apparently been treated in the process of manufacture, were found in the overcoats. The extreme solubility of the chlorid of zinc caused it to be taken up and carried with the dripping water to the edges of the garments and so in contact with the skin. The warmth of the skin caused evaporation of the liquid and consequent concentration of the solution so that it produced the powerful escharotic effect which chlorid of zinc, even in weak solutions, is known to have. Had these cases occurred sporadically and been treated by a number of medical men who had seen but one or two the discovery of the etiology would not have been so easy. The cases will be of importance to dermatologists in pointing out a, perhaps more frequent source, than is usually supposed, of *dermatitio venenata*.

Physical Differences of Colored and White Children.—In a recent number of the *American Anthropologist* Dr. Ales Hrdlicka, the Assistant in Anthropology of the Pathological Institute of the New York State Hospitals, described the physical differences he found to exist, after a series of careful examinations, between white and colored children. As some recent interest manifested in the dif-

ference between the newly born of the two races may extend to children of a larger growth, we abstract some of the details. Dr. Hrdlicka examined 1400 children, 300 of whom were negroes. He found that the whites had more diversity of physical peculiarities, the negroes showing distinctly more uniformity in this respect. Though the negroes were on the average taller by one to three centimeters (nearly one-half to one and one-fourth inches), the whites averaged heavier in weight. The negro head is smaller in size. The dentition of colored children is much more regular than that of the whites and their irregular setting of the teeth so common in white children is very rare in the colored. The arms are longer relatively to the height in the colored. In boys the penis is longer. The colored girl up to the age of puberty remains much more like a boy than does her white sister. Many white girls present, even at as early an age as eight, distinctly feminine characteristics, the waist is somewhat constricted, the hips have become prominent, the thighs are fat and rounded in marked contradistinction to the muscular contour of the boy at a corresponding age, and the shoulders and thorax are suggestively feminine in outline. We think that these racial details of the formative stage give an excellent chance to theorists. There is undoubtedly a basis in some of them,—the smaller heads, the longer arms, etc., of the negro,—for the anthropological theory that the negro is nearer the animal ancestor from whom man proceeds in his evolution; on the other hand, the want of uniformity and their running to weight rather than height might be made to argue degeneration on the part of the whites. The sociologist may find a reason in the precocious development of femininity in white girls to berate the modern social system that is evidently bringing this about. It is a long while since the sacred writer said that the earth was given over to the discussions of men, but the field is still open.

"Infectious Disease Reporting" under a Fee System.—Dr. Paddock Bate of Bethnal Green, London, in his annual report for 1897 points out some of the tribulations confronting a health officer when the local physicians are allowed a fee for making reports of contagious diseases. The notification fee is half a crown, or about sixty-three cents. Duplicate reports were received and paid for in nearly six per cent. of the total certification. It would appear that the law is so framed as to unintentionally permit of the payment of partners in a medical firm if each of them reports the same case. Dr. Bate says this duplication of certificates represented a cost of $65, and that the expenditure of this sum is pure waste, though unavoidable by the wording of the law. In nine instances the notification certificates were withdrawn by the reporter, the lapse of time having afforded an opportunity to amend the original diagnosis. In ten cases there were no grounds to justify the practitioner in reporting the case as one of infectious disease. "A certain medical man certified thirteen cases of membranous croup within a month. I made no examination of the first half dozen, but could not help noticing that the patients did not appear urgently ill when the premises were visited in the ordinary course of my duties. One morning four of these certificates were sent in, whereupon notice was given the certifier that I should personally examine these and any future cases of membranous croup he might report. I did so, but failed to find symptoms of laryngeal obstruction in any instance. I reported the result of my examination to the Sanitary Committee and the fees for the certificates were disallowed as to the cases I had personally investigated, together with another certified on post-mortem examination only. This was the subject of an inquest. The child was found dead in bed; the jury brought in a verdict of suffocation on the medical evidence; on the same afternoon I received a notification that the child had suffered from membranous croup, though nothing was said about this at the inquest. I may just mention that this was the only fatal case out of the whole thirteen, a magnificent testimonial to the skill of the doctor, supposing his diagnosis to have been correct. The medical man, referred to, wrote protesting against his fees being disallowed, but took no further action beyond ceasing to certify membranous croup."

CORRESPONDENCE.

INHALATION OF CAMPHO-MENTHOL IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—Every sign and symptom which will in the early diagnosis of pulmonary tuberculosis will be of great value to the physician. The ordinary physical signs are familiar to us all. There is one subjective symptom which has proven of very great value to me in revealing an early pathological change in the lungs in those cases in which the ordinary physical signs were absent. This diagnostic sign I have used for the last four years and have followed up the cases subsequently, and almost without exception it has proven to be trustworthy. It is a well-known fact that in pulmonary tuberculosis one side usually becomes affected first, and furthermore, that the process is usually more severe on one side than on the other. The diagnostic symptom as used by me is as follows: If the patient is made to take a deep, strong inhalation of campho-menthol in albolene (20 drops to ʒi) from an atomizer at thirty-pound compressed air-pressure, and he then be asked upon which side of his chest he feels most distinctly the cooling sensation of the campho-menthol, he will almost invariably tell you on the least affected side, and the degree of cooling sensation will be less the more diseased the lung tissue should be. In cases in which there is marked consolidation on one side and very slight on the other the patient may even be unable to feel the cooling sensation whatever on the most affected side. If in the very earliest stages, when the ordinary physical signs fail and something leads one to suspect from the history that pulmonary tuberculosis is present, he makes use of the campho-menthol inhalation, and if he then notes that the patient says the cooling sensation is decidedly more distinct on one side than on the other he will almost invariably find that later the side of less-

distinct sensation will show the ordinary physical signs of pulmonary tuberculosis.

This test is, of course, not meant to apply in acute pneumonia or capillary bronchitis and acute pulmonary troubles of this kind, but simply in those cases in which there is a suspicion of pulmonary tuberculosis. Even in such cases as these, however, it might show the symptoms of some consolidation and exudation in the smaller bronchial tubes, yet I have never had occasion to test it in these cases. I have had cases in which there were absolutely no signs of anything but a chronic bronchitis, and yet these same patients under the campho-menthol test have revealed pulmonary tuberculosis which later became fully developed. In simple chronic bronchitis the patient will feel the whole chest glow with the cooling sensation almost as perfectly as in normal lungs, and yet when tuberculosis is present even though they are strong and hearty the sensation may not be felt below the top of the sternum.

Perhaps there are others who have noted these same symptoms, but I have never seen them recorded. I should be glad to have the test given by others and to see published honest criticisms, even though adverse, for I do not claim that it is an infallible sign.

DUNBAR ROY, M.D.

ATLANTA, GA., January 18, 1899.

AGAIN THE COLOR OF NEGRO BABIES.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—In regard to the controversy now raging on both sides of the Atlantic as to the color of negro children at birth the following opinion of a recent writer on African anthropology (Mr. H. Ling Roth, in the *Journal of the Anthropological Institute*, London, n. s., 1, p. 104) is notable for its amusing concisiveness: "Pure negroes when born are pink, like young rats; at the end of about three or four months they become black."

F. H. GARRISON, M.D.

WASHINGTON, D. C., January 9, 1899.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

CELEBRATION OF THE FIFTIETH ANNIVERSARY OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY (CONTINUED)—THE SAMUEL D. GROSS PRIZE OF THE PHILADELPHIA ACADEMY OF SURGERY — SOME SPECIMENS PRESENTED AT THE PATHOLOGICAL SOCIETY—A SANATORIUM FOR CONSUMPTIVES PROJECTED—ELECTION OF OFFICERS OF THE MONTGOMERY COUNTY MEDICAL SOCIETY AND OF THE GLOUCESTER COUNTY MEDICAL SOCIETY — PERSONAL NOTES—OBITUARY.

PHILADELPHIA, January 24, 1899.

ON Sunday evening Rev. Dr. K. Boyce Tupper delivered a lecture on "The Ideal Physician," at the First Baptist Church. St. Luke was the ideal physician. The requisite qualifications are manliness, love of calling, and high spirituality. After the sermon a collection was taken up for the Mutual Aid Society, an institution with in the County Society, for which a substantial sum was raised.

Monday evening about 350 members were present at the dinner which was held at Horticultural Hall. Dr. S. Solis Cohen presided with Dr. Jacobi of New York at his right and Mr. Baugh at his left. Dr. Cohen acted as toastmaster; the first toast, "Our Founders," was responded to by a letter from Dr. Stillé, one of the founders, who was unable to be present. Dr. W. W. Keen responded to "The Philadelphia County Medical Society," in which he eulogized its early members, not only for their part in its founding, but for their skill. Ten of the fifteen original members had become authors, he said, and their books well bear inspection.

Mr. Daniel Baugh then spoke of "The Medical Journal" and the Rev. Dr. Charles Wadsworth, Jr., responded to the toast, "The Clergy," in which he pleaded for true fellowship between the professions. "The Law" and "The Newspaper" were responded to by Dr. E. W. Holmes and Talcott Williams. Among the invited guests were M. S. French, Captain Charles Lawrence, Justus C. Strowbridge, Samuel H. Ashbridge, James M. Beck, Dr. W. Murray Wildman of Reading, Dr. Hunsburger, President of the Bucks County Medical Society; Dr. Fretz, President of the Montgomery County Medical Society; Dr. Howard Kelly of Baltimore, H. G. McCormick, President of the State Examining Board, and J. P. Remington.

The second of the prizes to be awarded under the will of the late Dr. Samuel D. Gross, to be known as the Samuel D. Gross prize of the Philadelphia Academy of Surgery and consisting of $1000, will be awarded January 1, 1900. The essay must be written in the English language, must be the work of but one author, who msut be an American citizen, and must he founded upon original investigations in surgical pathology or surgical practice. The essay must not exceed 150 printed pages and must be published by the successful author in book form, a copy of which is to be presented to the Samuel D. Gross Library of the College of Physicians.

Essays may be sent to Dr. J. Ewing Mears, 1429 Walnut street any time up to January 1, 1900, and must be designated by a motto as is usual.

At the last meeting of the Pathological Society, Dr. de Schweinitz presented some interesting eye specimens. One was a spindle-cell sarcoma removed from the conjunctiva of a woman, aged twenty-eight, in whom it had grown most rapidly after child-birth. There has been no recurrence though her child has a birth-mark occupying a similar position in its eye. Dr. Wadsworth read a paper on "Indicanuria," which was discussed by Drs. Pearce, Stengel, Boardman Reed, and Hare. Dr. Wadsworth claims that its presence or absence is of clinical importance and is characteristic of functional inactivities or perversions. Discussion revealed a belief in its occurrence in intestinal putrefaction and the opinion that its value was far from being determined.

Dr. Joseph McFarland presented a specimen of complete exfoliation of the mucous membrane of the vagina which occurred in a woman aged thirty. These exfoliations

had occurred during a period of three years, but the intervals are now about five days apart. Dr. Stengel said he had seen a similar case. In Dr. McFarland's case there was no history of syphilis.

The report of the Loomis Sanitarium for Consumptives, in the Adirondack Mountains in New York, has given new impetus to a discussion which was started last year as to the advisability of establishing a similar institution in the Pocono Mountains in this State. For many reasons such a sanatorium would be a Godsend to the consumptive poor in Philadelphia, for the heavy expenses of traveling and the distance from home and friends render the Adirondacks and other health-resorts impossible to the large majority of patients who are particularly suited by their condition to climatic treatment. The healthfulness of these Pennsylvania mountains has long been known, and several reports as to the freedom of their inhabitants from pulmonary complaints have been published at different times. Climatic conditions are very similar to those existing in the Adirondacks, and as the distance from this city is only about one hundred miles, this accessibility is an advantage which counts for a great deal.

The probability of such a sanatorium being established rests largely, at present, upon the success of the efforts now being made by a physician in this city who is greatly interested in this particular work. A number of wealthy men have been approached, and some have signified their willingness to contribute various sums to aid in putting the project through. It is be hoped that the experiment will be made, for it seems to promise a great deal toward ameliorating the condition of a number of these unfortunate people, and while the Loomis-Sanitarium report is inclined to be optimistic, no one can question the good results obtained in many cases. It is only a step toward the ultimate segregation of consumptives which apparently is looming up before the minds of many advanced physicians as a necessary and inevitable step in combatting this disease.

The annual meeting of the Montgomery County Medical Society, for the purpose of electing officers, was held at Norristown, Wednesday, January 18th. Delegates to the American Medical Society and to the Pennsylvania State Medical Society and these officers were elected: President, Dr. D. H. Bergy; recording secretary, Dr. H. H. Whitcomb.

The Gloucester County Medical Society met at Woodbury on Thursday, January 19th, and after electing officers adjourned to attend the Society's annual dinner: President, Dr. Charles E. Heritage; secretary and treasurer, Dr. George E. Reading.

At a business meeting of the Philadelphia County Medical Society, held Wednesday, January 18th, the officers nominated last October were elected, Dr. Lindsay's death causing the only change in the list published in the NEWS of October 29th. Dr. Elwood R. Kirby was elected in Dr. Lindsay's place as secretary, and Dr. William S. Wray succeeded Dr. Kirby as assistant secretary.

Dr. William J. Taylor has been elected to fill the vacancy caused by the resignation of Dr. W. W. Keen as surgeon to the Orthopedic Hospital and Infirmary for Nervous Diseases, and the latter has been elected consulting surgeon.

Dr. Robert S. McCoombs, a graduate of the University of Pennsylvania, died last week of pneumonia following an attack of influenza, aged fifty years. He was prominent in church work, being a member of the City Missionary, the Historical, and the Church Extension Societies of the Methodist Church.

MEDICAL MATTERS IN CHICAGO.

CONSERVATIVE TREATMENT OF UTERINE MYOMA—APPROPRIATION FOR MEDICAL LABORATORY—OFFICERS OF CHICAGO OPHTHALMOLOGICAL SOCIETY—STATE BOARD OF HEALTH MATTERS—CHICAGO SOCIETY FOR THE PREVENTION OF TUBERCULOSIS—HYDROTHERAPEUTIC DEPARTMENT OF THE ALEXIAN BROTHERS' HOSPITAL—IMPLANTATION OF THE URETERS IN THE RECTUM—SYMPOSIUM ON THE MECHANICAL TREATMENT OF MALPOSITIONS OF THE UTERUS.

AT a meeting of the Chicago Medical Society, held January 11th, Dr. E. C. Dudley presented a paper on the treatment of uterine myoma, as illustrated by a series of cases. He offered for consideration two cases in which two tumors, both apparently springing from the uterus and each occupying the space between the folds of the right broad ligament, were removed. After reporting the cases in detail, he discussed conservative surgery in myomectomy. The removal of the myoma and the preservation of the uterus with or without utero-vaginal drainage is coming to be more and more the operation of election. Eleven years ago he reported a case of myomectomy by abdominal section and drainage from the interior of the uterus into the vagina. In this case no portion of the uterus was removed. Since this time Senn, Kelly and others have in many cases and with various modifications made use of the same principle until now the conservation of the uterus in myomectomy is not only an established, but bids fair to become a frequent, operation.

Intramural tumors, even though quite large, may often with the greatest ease be shelled out of their beds and the uterine wounds successfully closed. The tumor cavity, if not too large, may be obliterated by closure with numerous interrupted or continuous buried catgut sutures, and finally the peritoneal margins of the uterine wounds are united by a close row of rather deep Lembert sutures. During the enucleation of the tumor and the closure of the uterine wound, hemorrhage is controlled by a temporary elastic ligature around the cervix uteri. Before closing the abdominal wound this ligature is removed, and a little time is allowed to make sure that there is to be no hemorrhage from the uterine wound. Hemorrhage is usually in a great measure controlled by the uterine contraction which follows the enucleation. The mortality of this method for small tumors, in which the traumatism is slight, is surprisingly small. In case of a large tumor, and consequently of large traumatism

with enormous surfaces to be united by buried sutures, closure of the uterine wound involves too great danger of sepsis, and the technic should be modified as follows: After the tumor has been shelled out from the uterine wall, an opening is made directly from the tumor cavity to the uterine cavity. If the uterine canal is patulous, a continuous strip of gauze is carried from the tumor cavity directly through into the vagina, and the tumor cavity packed with the same continuous strip. The temporary elastic ligature around the cervix does not interfere with the introduction of the gauze. The uterine wound is then closed, as above described, by buried sutures and deep Lembert sutures of catgut. The peritoneal margins of this wound, thus turned in and united, rapidly grow together, and the whole uterine traumatism, now isolated from the peritoneum, is adequately drained through the vagina. No abdominal drain is required. If the uterine canal is not sufficiently patulous, it may be dilated or bilaterally incised or it may be both dilated and incised. The vagina is loosely filled with gauze to meet that which protrudes from the uterus; an absorbent vulvar dressing, to be changed as often as it become moist, completes the capillary drain. The gauze is removed in two or three days. Care is necessary in the closure of the uterine wound that the gauze be not caught in a suture, because then its removal would have to be postponed until after the absorption of the suture.

As shown in the two cases reported, the same principles will apply also to an intraligamentous tumor.

His own experience during several years with the above technic shows (1) almost entire freedom from mortality; (2) prompt and uneventful recovery; (3) the most gratifying permanent results. The method is undoubtedly applicable to a much larger number of tumors than is generally supposed.

Drs. William E. Quine and W. S. Christopher, representing the college of Physicians and Surgeons, appeared before the Board of Trustees of the University of Illinois January 13th, and asked for an appropriation of $50,000 for a medical laboratory at the institution. The request was granted.

At the last meeting of the Chicago Ophthalmological and Otological Society, Dr. Lyman Ware was elected President; Dr. C. D. Wescott, first vice-president, and Dr. C. P. Pinckard, secretary-treasurer.

The State Board of Health held its annual meeting January 17th. The most important business of the meeting consisted of recommendations of the Board as to legislation. Dr. J. A. Egan, the secretary of the Board, recommended the following legislation to the consideration of the Board:

First. The creation of a State Board of Medical Examiners. The bill as prepared provides for a board of seven members and a secretary, which board shall be self-supporting. The duties of the board will be the examining and licensing of physicians and midwives and the supervision of medical colleges. *Second.* The creation of a local Board of Health in every city, village, and town, and every county not under township organization. Under the present law such boards may be appointed, but no duties are prescribed by the laws of the State. *Third.* An act forbidding the interment or cremation of a body dead from any disease without a permit of the nearest health officer, and requiring all health officers to make a bi-monthly report to the State Board of such permits issued. *Fourth.* Supervision of public water-supplies and sewerage. *Fifth.* A more liberal appropriation. The appropriations in the past are held to have been entirely inadequate for the purposes for which they were made. *Sixth.* To compensate owners of cattle condemned for tuberculosis if the owner was ignorant of the existence of the disease when he purchased the stock, and fixing a severe penalty against owners who fail to report the existence of the disease among their herds. *Seventh.* A general revision of the act creating the board, as the attorney-general has given it as his opinion that the act is weak in many places and might easily become inoperative. Another matter which came before the Board was the consideration of reports of sanitary inspections made in State institutions during the last quarter.

Ignorance as to the origin and nature of consumption and other tubercular diseases is almost universal and serves as an agent for their dissemination. To combat this, to enlighten the public in general and the sufferers in particular, so that all may intelligently assist in preventing the further spread of the contagion, and thus ultimately stamp it out, will be one of the first endeavors of a new organization, which will be known probably as the Chicago Society for the Prevention of Tuberculosis. At the initial meeting Dr. A. R. Reynolds, health commissioner, presided and appointed a committee on organization, with Dr. Frank W. Reilly, assistant health commissioner, as chairman. Steps were taken at once to lay a solid and enduring foundation for the work of the society, and one of the first and most important of these was to invite individual members of the medical profession to furnish in writing their suggestions and ideas as to the scope, method, and form of the organization. Besides Dr. Reilly, the organization committee includes Drs. Fernand Henrotin, Frank Billings, Frank S. Johnson, W. A. Evans, Homer M. Thomas, John A. Robison, and N. S. Davis, Jr. No doubt is entertained that hygienic measures, such as isolation of patients, disinfection of sputa, and scrupulous cleanliness in public conveyances, must tend to reduce the number of deaths by consumption. A gratifying feature of the movement is the enthusiasm and disinterestedness of the physicians of all schools who are urging and organizing it. To what extent the plans of the society may go depends largely on the philanthropic assistance it will get in the form of contributions. Once the possibilities are made plain, for the experiment is succeeding in other parts of the world beyond expectation, the wealthy and public-spirited citizens of Chicago, it is anticipated, will support the movement handsomely. The doctors are encouraged in this belief by one individual case of magnanimity. This is the $60,000 gift of Otto Young for the Consumptive Hospital annex to the Home for Incurables.

The Alexian Brothers' Hospital has been handsomely

rebuilt, with all the equipments that hospital hygiene demands. A new department has been established during the past month, namely, for the cure of diseases by means of the rational application of water, of electricity, of massage, and Swedish movements.

At a meeting of the Chicago Gynecological Society, held January 18th, Dr. Franklin H. Martin presented specimens and post-mortem findings from three dogs in which the ureters were implanted in the rectum. Union between the ureter and intestine was technically perfect, and it will be of considerable interest to examine at some future time sections through these parts. No attempt was made in any of the cases to protect the ureters from invasion of bacteria from the bowels by any valve device in the technic. The ureters were implanted singly. The anastomosis of the ureter with the bowel was made in each case perpendicularly or at right angles to the axis of the intestine. The three dogs represented the successes in thirty-four dogs operated upon, the other thirty-one having died within one week after the operation from various causes associated with the technic. Dr. Martin has devised a new operation for implantation of the ureters in the rectum by which he hopes to prevent infection of the ureters by the colon bacilli and other bacteria from the bowel. His experiments have been undertaken with the idea of making removal of the human bladder a feasible operation.

At this meeting there was a symposium on the mechanical treatment of malpositions of the uterus. Dr. E. C. Dudley read a paper on general principles, indications and contraindications of mechanical support for uterine deviations. He said that a pessary is always contraindicated until the uterus has been replaced. Failure of replacement will cause it to press upon the sensitive uterus, and one of three unfortunate results may occur: (1) The pessary may not be tolerated on account of pain; (2) it may be forced down by pressure from above so near to the vulva that it will fail to do the least good; (3) the uterus, finding it impossible to hold its position against the pessary, instead of taking its proper position, may be bent over it in exaggerated retroflexion, with the cervix between the pessary and the pubes, or the whole organ may slip off to one side of the instrument into a malposition more serious than the one for which relief is sought.

Dr. Franklin H. Martin spoke on electricity in the mechanical treatment of malposition of the uterus, and stated that electricity in the form of the faradic or the sinusoidal current, slowly vibrated, will cause contraction of the striped and unstriped muscular fibers in the female pelvis. It is also a smart promoter of nutrition. Displacements of the uterus dependent alone on muscular relaxation or muscular non-development, if curable at all without operation, can be cured better and quicker by electricity than by any other treatment now resorted to.

Dr. William H. Rumpf discussed the use of massage in the treatment of uterine malpositions, saying that in retroflexions massage has given him personally more satisfactory results than any other form of treatment, and this pathological condition is the most important field for pelvic massage. He considers massage a valuable adjunct in the treatment of retroflexions of the uterus. He believes about fifty per cent. of the patients will be completely cured, and the rest will be well prepared for further treatment with pessaries or operations.

Dr. Thomas J. Watkins spoke on tampons and pessaries in displacements. He considers that fine, sterilized lamb's wool is the best material to use for tampons in these conditions on account of its elasticity. The value of tampons depends upon keeping the uterus as near its normal plane in the pelvis as possible, and the elasticity of the tampons elongates any adhesions that may prevent reposition of the lower segment of the uterus. Tampons, in order to be effective, should be used almost continuously, that is, soon after one tampon is removed another should be inserted. Pessaries are of especial value in some cases of simple retroposition of the uterus during the second and third months of pregnancy. Retroposition of the uterus complicated by adhesions may be treated with tampons supplementary to massage and finally relieved by a pessary. The routine use of pessaries, carelessness in studying the indications and contraindications for their use, and negligence in the proper selection of the instrument to each individual case have done much harm and cannot be too severely criticised.

OUR LONDON LETTER.

[From Our Special Correspondent.]

THE IMPORTANCE OF LORD IVEAGH'S MUNIFICENT GIFT TO THE JENNER INSTITUTE—SLACK QUARANTINE METHODS—TRIAL OF A PHYSICIAN FOR IMPROPER TREATMENT OF INVERSION OF THE UTERUS—THE LATE PROFESSOR KAUTHACK—THE "KNOCK-OUT" BLOW IN ENGLISH SCHOOLS.

LONDON, January 12, 1899.

THE press, both lay and medical, is still ringing with the praises of Lord Iveagh for his superb gift of a quarter of a million pounds sterling to the Jenner Institute of Preventive Medicine. And they do well to make much of it, for it is the first step toward remedying a great and serious lack in British medicine, which no one who is at all familiar with Continental medicine can fail to be struck with. While two-thirds of the original research work in Germany and France, such, for instance, as that of Koch and Virchow and the later part of Pasteur's, is done in laboratories equipped by and on salaries paid by the State, here similar work has to be done in the spare moments of earning an income by practice or teaching, just as in America. Indeed, the situation is even worse here. Poor Kauthack, whose splendid work makes his early death deeply regretted, not only by those who knew him personally, but by the entire profession, only as lately as five years ago, when he already had a national reputation, had to leave the laboratory and actually attempt to enter private practice in a provincial town. Only a few weeks since I was talking with a man who ten years ago was the most promising of young English pathologists, and asked him why he did not continue in research work. "There was absolutely no income to be had or hoped for from it," he said, "and I had to earn a

living." So he, too, entered practice and is now a mere successful operator and consultant. It is not too much to say that two-thirds of the original research carried on in London is done by young men who will be obliged to use it as a stepping-stone to practice. It is to be hoped that Lord Iveagh's gift may open the way to a better state of affairs.

This is the second stroke of luck recently enjoyed by the recipient of this princely donation, the Jenner Institute. Originally founded some years ago under the name of "The British Institute of Preventive Medicine," it was struggling along in the usual condition of holy poverty characteristic of purely scientific enterprises, when the managers of the fund which had been raised to perpetuate the memory of Sir William Jenner, offered to present it to the Institute if it would change its name to "The Jenner Institute of Preventive Medicine." As the fund amounted to about $110,000, the offer was was as promptly accepted as the like ever was by penniless maiden, and then before the public had got used to the new name, this other windfall descended. It seems more than probable that the first donation was one of the principal means of attracting the attention of the last benefactor to its needs.

An interesting illustration of English quarantine, or rather of the way the Britishers get along without it, has been given lately by the arrival of two vessels at the port of London, each of which had had one or more cases of bubonic plague on board during the voyage. One of them, the "Caledonia," arrived some two weeks ago, the other, the "Golconda," a few days later. Both touched at Plymouth, were there boarded and thoroughly inspected by the health officer of the port, ordered to disinfect, and permitted to proceed to London without more than a couple of hours' delay. Arrived here they were again inspected and thoroughly disinfected, one seaman on the "Golconda" with suspicious symptoms sent to an isolation hospital, and both crews detained on board for a few days, but all the passengers, after inspection, were permitted to proceed to their destinations in different parts of England. The health officer at each of the places for which they were bound was notified by telegraph and will keep them under serveillance by daily visits for some weeks. This looks like the flimsiest of protection against contagion, and yet during the nearly thirty years since quarantine was abandoned in Great Britain, with all the world's commerce which surges into her harbors, not a single epidemic of infectious disease has been introduced from without.

A case of mammary cancer with great enlargement of the axillary and clavicular glands at Mr. Jonathan Hutchinson's recent clinic, drew from the lecturer some interesting comments upon "competition" between secondary and primary deposits in malignant disease. He had seen a number of cases in which the enormous development of secondary growths in glands and elsewhere had actually seemed to impair the nutrition of the primary tumor, which accordingly diminished markedly in size and might even have disappeared. This was particularly noticeable in malignant growths of the testis. He had twice been consulted within the past few years by patients on account of large abdominal tumors which on careful examination were found to be sarcomatous enlargements of the lumbar glands secondary to sarcoma of the testis. In one patient the testicle was found almost completely atrophied while in the other it appeared at first sight to be little altered, but on examination it was found to be changed into a mass of fibrous tissue. Both patients stated that the testicle was first diseased but had "got better" about the time abdominal swelling began.

The late Baron Ferdinand de Rothschild left a legacy of $500,000 to the Evalina Hospital, which he founded nearly thirty years ago in memory of his young wife, and $5000 each to St. George's Hospital and the Brompton Hospital for Consumptives.

And still the profession is before the public in the courts. This time it is a practitioner named Nugent who really appears to have deserved it. He is accused of causing the death of a woman by failure to recognize and correct that rare accident, inversion of the uterus. The inversion and his failure to recognize it seem to be practically proved by the unwilling testimony of the physician whom he called to his assistance, but how far this neglect was the cause of death seems doubtful. A curious feature of the case is that the doctor's name does not seem to be Nugent but Roland, "Nugent" being the name of a deceased physician at Dulwich to whom Roland was an assistant and whose name and place on the register of practitioners he seems to have assumed. Even in model England there appear to be ways of evading the Medical Practice Act.

The career of Professor Kauthack, whose untimely death from cancer of the liver at the age of 35 was noted last week, was a remarkably brilliant one. Born in Brazil of Spanish parents he came early to England and was educated at Liverpool Medical College. When only twenty-six he contributed an article to *Virchow's Archives* on the "Histology of the Larynx" that attracted wide attention. At twenty-seven he was appointed a member of the Leprosy Commission and spent two years in India, and on his return was elected Walker Research Scholar at Cambridge. At the end of his term in 1892, he went to Liverpool to enter practice, but was soon recalled to London as Director of the Pathological Laboratory at St. Bartholomew's Hospital, which position he held until his appointment as Professor of Pathology at Cambridge only a year before his death. His best known work was his investigations of leprosy, his study of the tsetse-fly disease, and a report upon tuberculosis in milk. In the barely ten years of his professional career he had achieved a remarkable reputation, both as an investigator and a teacher.

The vagaries of latter-day athletics in schools is truly remarkable. We have this week had the edifying spectacle of the Association of Head Masters, representing the leading schools of England, finding it necessary to publicly protest against the "knock-out blow" being taught in school gymnasia! The stroke in question is not a shoulder hit, but one delivered from the side,

technically called a "jab" or "hook," and neatly landed upon the point of the chin with the gentle anatomical aim of driving one condyle of the jaw against the base of the skull with sufficient force and suddenness to produce a mild concussion of the brain and temporary unconsciousness. Its object is, in the language of the ring, to "put a man to sleep" long enough for him to be counted out. So little force is required to make it effective that one of the distressed head-masters told of a fourteen-year-old boy, boxing with a professional instructor in a school gymnasium, who took it into his head to try this blow, with the result that the pugilist fell as if he had been shot, and remained unconscious for several seconds. And this delicate and harmless maneuver is being taught to school boys. It is time somebody protested in all conscience.

A few weeks ago a number of street-cleaners at Birmingham had their wrists and ankles badly burned by chlorid of zinc with which their cleaning suits had been treated in process of manufacture. Now it is reported that certain brands of flannelette are heavily charged with the same salt and for a curious reason. It seems that in their "natural" condition these cloths are extremely inflammable and, like celluloid, will blaze up if brought near a flame. Consequently the makers cast about for some salt which was so highly hygroscopic, that the goods would always be kept slightly damp. Of all other good and harmless things they hit upon chlorid of zinc, and one sample just examined was found to contain no less than 23 per cent. of the salt, and 8 per cent. of water. The analyst, therefore, naively advises purchasers to "avoid flannels having any feeling of dampness." We should think so. We have all heard much of the dangers of damp flannels, but this is a new variety.

DIFFERENT METHODS OF CURE OF AN IMMOVABLE MAXILLA—CALOT'S FORCED-REDUCTION METHOD—STENOSIS OF THE ESOPHAGUS FOLLOWING SCARLATINA—LORENZ DEFENDS HIS OPERATION—RELATIONS OF OBLITERATING ENDARTERITIS TO SPONTANEOUS GANGRENE—VALUE OF THE DIAZO-REACTION IN TYPHOID FEVER.

AT the Berlin Medical Society, November 30th, KAREWSKI spoke of the different methods of cure of an immovable under jaw. The lesion can be due either to destruction of the joint or to loss of the soft parts and their replacement by fibrous tissue. The latter condition is a difficult one to remedy; still plastic operations upon the cheek have not been without effect, when there was no osteoperiostitis present. For relief of ankylosis a number of operations have been planned. Esmarch suggested the establishment of a false joint; others have proposed to separate the bones and introduce some soft tissues between the ends, but the results have been indifferent. The best method seems to be to remove a considerable portion of the bone, combining this with a plastic operation on the cheek. This plan had been followed in the case of a woman who, ten years before, had inflammation of the brain followed by an abscess in the cheek. There resulted a broad bony plate which connected the left superior maxilla with the under jaw, and also a large scar in the soft parts. The bone was freely cut away and the defects in the soft parts replaced by a flap from the neck. The result was excellent, the patient being able to open the mouth a distance of 4 cm. (2.5 in.).

At the Free Union of Surgeons of Berlin, December 12th, CALOT gave an exhibition of his method of forcible reduction by applying it to two patients. The first case was that of a child, three years of age, who had had spondylitis for three months. Under an anesthetic the child was suspended and during manual extension of the feet Calot was able by slight manipulation to accomplish a complete reduction of the deformity. A large plaster-of-Paris bandage was put on, covering the body and the neck well up to the head. The time of the whole procedure was only fifteen minutes. The child could stand as soon as it recovered consciousness. The second case was one of eighteen-months' duration with marked deformity. This child had been subjected to a great deal of treatment. Under an anesthetic an incision was made over the prominent vertebræ, and the upper part of the sunken spinous process was removed. The periosteum and soft parts were loosened on both sides. The wound was closed by catgut sutures. The child was then stretched upon the table and the deformity was reduced without the application of much force being necessary. Suspension and a plaster-jacket completed the treatment. The time occupied was scarcely more than fifteen minutes. The preliminary operation had the threefold advantage of facilitating the reduction of the deformity, avoiding pressure necrosis of the skin, and of providing a strong support in the way of new bone to be formed, as the operator hoped, in one piece, from the ripped-up periosteum. The after treatment of such patients extends over at least a year and a half. Calot will not receive into his hospital for treatment any children whose parents will not agree to leave them with him for years if need be. The plaster jackets are changed about once in two months.

In Stettin, November 8th, EHRLICH showed a second case of stenosis of the esophagus following scarlatina. A man, aged thirty-two years, had scarlet fever at the age of eighteen months, followed by difficulty in swallowing. The difficulty increased very much during the last few years and especially during the last months, so that he finally became unable to swallow even fluids. After food had been washed out of the esophagus Ehrlich could make out, by means of the esophagoscope, a stricture 32 cm. from the teeth, having a three-cornered opening about 3 mm. across. A stick of laminaria was passed into it and in the course of ten days it was stretched to admit a sound of 10 mm. diameter. The esophagoscope can be readily passed without the introduction, into the mouth, of the finger, if the patient's head is kept flexed until the instrument touches the posterior wall, and the head is then fully extended. In this simple manner the point of the instrument is lifted over the prominent seventh cervical vertebra. Apparently scarlet fever occasions

stricture of the esophagus by no means so rarely as has been supposed. Doubtless many of the so-called idiopathic or congenital strictures are due to it.

At the Imperio-Royal Society of Physicians of Vienna, November 25th, LORENZ defended his method of the bloodless reduction of congenital dislocation of the hip against attacks which have been made upon it by French surgeons. Lorenz's method consists in bringing the head of the femur into the rudimentary acetabulum by means of tension and extreme abduction of the thigh, and of keeping it there from six to nine months, until the head of the bone by means of muscular pressure, and later by motion, shall grind out for itself a good acetabulum. It matters little whether the head of the bone is brought into the exact spot of the rudimentary acetabulum as long as it is on the anterior wall and covered by a rim of bone which will keep it in place. The results were splendid. Where a double lesion had existed the pendulous abdomen, the broad buttocks, and the waddling gait disappeared almost at once so that the form of the whole body was altered. As the best answer to critics Lorenz showed the photographs of a great many patients before and after they had been treated in the manner described, as well as radiographs and several patients themselves. The proofs of the correctness of his method were overwhelming.

STERNBERG read a paper on the relations of obliterating endarteritis to spontaneous gangrene. Without apparent cause there develop in the lower extremities of young, strong persons symmetrical pains, paresthesia and weakness. Later the gangrene begins at the periphery in the form of a blister and proceeds thence toward the center. Only exceptionally are the upper extremities affected. The veins usually remain normal, but the arteries show reduction of their lumens in places, due to an irregular growth inward of the intima. The muscular and outer coats of the vessels are unaffected. This obliteration of the lumen is not due to the organization of a thrombus, but consists in the growth of the intima itself and hence the names, endarteritis proliferans, hyperplastica, and obliterans. A similar, though physiologic, growth of intima is seen in the closure of the umbilical vessels and in the disappearance of the uterine and ovarian arteries. Thoma has explained this growth of the intima as due to a varying pressure caused by the diverting of the blood-stream through other channels. This theory satisfies the conditions found in the umbilical and uterine arteries, but when it is applied to the occurrence of pathologic growth of intima it is less satisfactory. It may pass for the occurrence of such a process in the neighborhood of tumors and inflammations, but it does not answer for simple cases of endarteritis, where there certainly is no dilatation of the arteries, though hypertrophy of the media might cause contraction.

At the Vienna Medical Club, November 30th, WOLF spoke of the value of the diazo reaction in typhoid fever. Ehrlich has stated that the reaction is of value only if a greenish precipitate accompanies the red color. Others have disputed this and Wolf shares their opinion. Analysis of the precipitate showed him that it was composed of triple phosphate and ammonium urate, and had nothing to do with the diazo reaction. The value of the reaction rests less in diagnosis than in prognosis. Thus it may also be present in miliary tuberculosis. If it is absent the conclusion may safely be drawn that the disease is either not typhoid fever, or if so that it is of a very light character.

At the session of December 7th, EWALD read a paper on the indications for the operative treatment of biliary calculus, a translation of which follows.

SELECTED ARTICLE.

INDICATIONS FOR THE OPERATIVE TREATMENT OF BILIARY CALCULUS.[1]

[Translated Especially for the MEDICAL NEWS.]

THE indications for the operative treatment of biliary calculus become of importance as soon as it is evident that a spontaneous cure is not to be anticipated, and that complications will follow which are either disabling or dangerous to life.

We must first consider the question of a spontaneous cure, including under that term medical treatment, especially that received at Carlsbad. Is there such a thing as spontaneous recovery? Every one of you will promptly answer "Yes," if by "recovery" is understood, merely the passage of the stone. You will answer with some hesitation if I insist that I mean by "recovery" the passage of all the stones; and your reply will come with still more hesitation, if "recovery" is understood to mean the cure of all the complications. I would like to make it plain at the outset, that a spontaneous recovery from biliary calculus is very seldom to be looked for, since an interval of freedom from pain, lasting for several years, is by no means the same thing as a definite cure; while the various complications, stricture, atresia of the passage and carcinoma may produce their evil effects years afterward, in spite of anything which we can do to prevent it.

Let us consider when a particular attack (and by that I mean not merely the attack of colic but also the passage of the stone and all the complications which follow) indicates that the physician should call on the surgeon for help. How can one determine whether a spontaneous passage of the stone is to be awaited, and how long shall it be waited for, and how can it be known when it has occurred?

If it is the first attack, there is nothing to go by, to prove that the stone will or will not be passed, and so we must wait and see. The answer to the first question, therefore, lies in the second. If it is not the first attack, it is of vital importance to know how previous attacks terminated, for from them we can draw conclusions as to the probable outcome of the attack before us. Here the answer to the first question lies in the third. We shall then answer that first.

The hoped-for termination of an attack, that is the

[1] An address delivered before the Vienna Medical Club, December 7, 1898, by Karl Ewald, M.D., Privat-docent for Surgery in Vienna. From the *Klinische Therapeutische Wochenschrift.*

passage of the stone, can only be proved by finding the stone in the stools. Suspension of the pain is in no wise a proof of the passage of the stone. No more is the disappearance of jaundice and the reappearance of bile in the stools. The finding of the stone in the feces is, however, largely a matter of chance, since it does not pass immediately after the cessation of pain. Sometimes it is dissolved or rubbed to pieces in the intestine, or it may, while maintaining its integrity, lodge in some pouch of the intestine, and be kept from appearing in the stools. The examination of all the stools is a tedious process, and only occasionally is a patient so situated that it can be done with requisite thoroughness. Yet only when the physician has the stone in his hand can he assert positively that his patient has had gall-stone colic, or that the stone has passed. Even then it cannot be said whether it passed through the common duct, or not. It is only fair to acknowledge all these difficulties, but in spite of them the examination of the stools may give the most valuable information and is greatly to be recommended.

Are there any other ways by which one can determine with even a reasonable degree of accuracy that a stone has passed the common duct? I must admit that there are none. If you rely on the repeated and typical terminations of attacks, you will be grossly deceived. I once operated upon a young woman who had had numerous typical attacks of one or many days' duration, and who sought operative relief on account of the frequency of these attacks, and the pain, which made her practically an invalid. We expected to find many small stones. Instead there was one smooth, round stone in the gall-bladder, which alone had caused all the attacks.

When a large stone is found in the stools, the question is raised whether it has passed by the common duct, or has ulcerated through into the intestine from the gall-bladder or some other part of the biliary tract. This cannot be determined from the size of the stone. I have seen a stone as big as a hen's egg lying in the common duct, and have known one scarcely smaller, to pass into the duodenum. Of course this is only possible when the passages have been dilated by numerous attempts of smaller stones to get through. If such previous dilatation has not taken place, a stone larger than a bean cannot get through in a short time.

And now to come to the second most important question, how long can we wait? The "we" in this question includes both physician and patient. If severe complications are already present, such as suppurative cholectitis, or cholangioitis, carcinoma of the gall-bladder, or atresia of the common or of the hepatic duct, the indications for surgical measures are clear enough. Indeed then it may be too late.

But in the lighter cases when these dangerous complications have not set in, the question should often be left to the patient to decide. It is not so much the immediate danger to life that makes an operation advisable, as it is the continued inflammation which will make it impossible for him to attend to his duties, or the repeated pain which takes away his pleasure in life, or the weakness that will follow the long disturbance of digestion.

It is worth while to refer here to the action of Carlsbad salts, about which opinions differ. Nobody claims that they will cure all cases without danger of complications. It may be admitted that they facilitate the passage of stones, but that they make such passages absolutely painless is not claimed by any one. Many experienced physicians dispute that a stone is passed any more quickly on account of their use. We may reject the idea that has been advanced that the use of Carlsbad water increases the flow of bile and that the stone is pressed out into the duodenum as a result. Were this the case almost all of the patients at Carlsbad would be jaundiced, whereas the reverse is true. Naunyn's experiments upon animals have shown that the Carlsbad sprudel salts have not nearly so powerful an action on the flow of the bile as a full meal. And the closure of the biliary passages by a stone, at least for any considerable time, is not so perfect that it is possible to establish any considerable pressure behind it. At the operations for gall-stones which I have performed when the stone was in the common duct, it has always been sufficiently loose to be easily pushed back and forth unless cicatricial tissue prevented.

The pain of a gall-stone as well as the jaundice is pretty generally recognized to be due to inflammation of the biliary passages; and it is now generally admitted that this inflammation is of infectious origin. The inflammation is usually of a mild character with serous exudation and limited fever of short duration. The danger of infection of the peritoneum by operation is therefore slight. This inflammation is favorably affected by the treatment at Carlsbad just as it is by warm, moist compresses. The Carlsbad waters are good symptomatic treatment therefore, but they do not reach the cause of the trouble and are incapable of affecting the more serious complications—stricture, carcinoma, cholangioitis.

In light cases with symptoms only of pain and gastric disturbances two possibilities are open to the patient: operation, which has as drawbacks, two weeks in bed, a biliary fistula of three- to six-weeks' duration, and an abdominal scar; or moist compresses with Carlsbad water internally, with more or less morphin, a treatment of uncertain duration which rarely cures the patient, but which may for a shorter or longer period lessen or remove altogether the disabilities from which he suffers. In the early stages of the trouble the danger from operation may fairly be said to be less than that from medical treatment since it obviates the possibility of subsequent complications, chief among them being carcinoma.

There is a possibility that a stone may be left after an operation, but the same possibility exists after medical treatment in a much higher degree. The more carefully the operation is performed, and the larger the stone, the less likely is this to happen. A recurrence after operation has never been absolutely proved, but it is, of course, not impossible. Even so it would not necessarily be the fault of the operation.

Under these circumstances it is evident that the man or woman who loves an energetic active life, or who is obliged to earn a living for a family, will not be as will-

ing to experiment with a Carlsbad cure, as the person financially better situated who is content to live there in comparative comfort until hard necessity in the form of cholangioitis or carcinoma compels a more radical treatment.

The commonest complication of biliary calculus is icterus. Can this make an operation necessary? It may continue for years, yes for thirty years, without threatening life. On the other hand, cholemia may set in in a short time. According to my opinion icterus alone is not an indication for operation unless it has continued for two or three months continuously.

Another complication almost equally common is fever. It is of far graver importance than icterus. If it is moderate and exists for only a short time, and without peritonitic signs or swelling of the liver, it may be disregarded. The oftener the attacks come and the longer they stay the more seriously must operation be considered, for the picture of a fatal cholangioitis grows plainer and plainer.

The mechanical obstructions which may develop in the course of the disease may be either relative, that is to say, stricture, or absolute atresia. They may arise in the biliary passages or in the duodenum or colon. If atresia arises in the cystic duct, a relatively common location, hydrops of the gall-bladder may develop, a condition which is with difficulty told from a stone in the cystic duct. Whether operation is necessary will depend on the symptoms. Atresia in the course of the hepatic or common duct is an absolute indication for operation, but it can hardly be told from a stone. Stricture of the intestine is readily recognizable and when well marked is an absolute indication for operation. Perforation of the gall-bladder may never be left to heal of itself as such an outcome is unknown.

Inflammatory complications may be limited or diffuse and serous and purulent. The former are naturally less serious than the latter. Of the more grave inflammations empyema of the gall-bladder and purulent cholangioitis with abscess of the liver are not infrequent. The more virulent the infection the greater the necessity of operation and the more dangerous the operation at the same time. The danger consists in infection of the peritoneum by overflow of bile.

Finally carcinoma must be mentioned, but upon this subject surgery has little more to say than medicine.

Adhesions between the gall-bladder or other portion of the biliary tract and the stomach may cause such pain and gastric disturbances as to threaten life from marasmus. In such conditions surgical measures will often bring about a quick and certain cure.

Removal of Foreign Bodies from under the Nail.—This is rendered easy and comparatively painless by the following procedure: apply a 10-per-cent. solution of caustic potash to the nail directly over the foreign body, using a match as a convenient applicator. Scratch the softened nail with a piece of glass, and repeat the whole process until the offending object is reached, when it can readily be lifted up and removed.

SOCIETY PROCEEDINGS.

NORTHWESTERN MEDICAL AND SURGICAL SOCIETY OF NEW YORK.

Stated Meeting, Held November 16, 1898.

THE Vice-President, WILLIAM STEVENS, M.D., in the Chair.

DISLOCATION OF THE HEAD OF THE HUMERUS.

DR. JOHN F. ERDMANN: The man from whom this specimen was removed gave the following history: He is German by birth, a sailor by occupation, and in mid-adult life. Six weeks before I saw him he was struck by a large wave and received a dislocation of the left shoulder. There was no medical man on board the vessel and no attempts were made at reduction. When he came to me a large mass was seen in front of the clavicle at its mid-portion, and there was what might be called a pre- and supraclavicular dislocation of the head of the humerus. I made all kinds of attempts at reduction under ether-narcosis, but although it was freely movable, I could not reduce the head of the bone into the glenoid fossa. I, therefore, cut down upon it and found it lying between the pectoralis major and the pectoralis minor. It was entirely without muscular or ligamentous covering, being absolutely denuded even of periosteum for a distance of 3½ inches; the deltoid was the only structure which was attached to it. The capsule had evidently been ruptured behind and below and the head wrenched outward and forward and then displaced up in front of the collar-bone. I was only able to replace the bone after cutting off the head. The wound, which was closed without drainage, healed by first intention although the patient suffered from a left lobar pneumonia. On the seventeenth day after the operation the man was able to lift his arm twenty degrees from the side of the body, and I have no doubt that he will eventually have excellent motion.

APPENDICITIS.

DR. ROBERT MILBANK: This appendix was recently removed by Dr. Lewis A. Stimson from a girl sixteen years of age who had had a number of slight attacks of appendicitis during the past eighteen months. With the exception of the last, these attacks were not severe enough to confine her to bed. She then complained of a great deal of pain and was obliged to remain in bed for several days. Her pulse was never above 80 and there was no rise of temperature. The appendix was found to be pulpy but was empty. There were, however, eight or ten hemorrhagic spots in the internal coat, some of which extended nearly through to the external surface. The patient made a good recovery.

EPIDEMIC DYSENTERY.

DR. S. H. DESSAU: I wish to report a case of dysentery of an epidemic type occurring in a child eight years of age. I have seen four similar cases this fall in the same part of town. It is a question whether or not the return of the troops from Cuba is responsible for the appearance of the disease. I successfully treated the child

with rectal injections of decinormal salt solution at a temperature of 105° to 110° F., two quarts of the solution being used each time. Six injections in all were given. Kemp's metal tube was employed. This is not so long as the rubber rectal tube, but by elevating the child's pelvis the solution was made to enter the bowel to a considerable height. The injections were followed by great relief, and the child was well at the end of eight days. This treatment has been recommended for subacute cases, but I have never heard of it being employed in acute cases. In looking up the literature I find that in a recent number of the *British Medical Journal*, Dr. Sandwith of Cairo, Egypt, recommends injections of hot water containing sulphate of copper, 15 grains to the pint, in acute cases of dysentery.

FRACTURE OF THE NECK OF THE FEMUR.

DR. H. L. TAYLOR: I recently saw a man at the hospital who stated that four months previously he had fallen down a hatchway of a vessel and injured his foot. He was immediately taken to one of the large city hospitals where the foot injury was treated. No examination of the hip was made and the patient was told to get up on the following day. The man now walks badly with a crutch and a cane and complains of pain in the hip. Upon examination I discovered that the left leg was three-quarters of an inch shorter than the right, the trochanter was elevated, there was considerable limitation of motion at the hip-joint, and crepitus was present; in other words, there was an ununited fracture of the neck of the femur. The fact that this condition was unrecognized while he was in the hospital shows the necessity for a thorough examination of all the joints after a severe fall.

LIGATION OF THE SUBCLAVIAN ARTERY.

DR. ERDMANN: Last week I ligated the subclavian artery in its third portion for aneurismal varix. The patient was a boy aged twenty years, a contortionist, who had been shot on the 18th of August last. The ball entered under the left clavicle, took an upward and outward course, and was removed from the supraspinous fossa. When he came to me he had a most beautiful murmur of the bee-buzzing type which could be heard all over the chest, left and right, posteriorly and anteriorly. Palpation failed to show the presence of a tumor. I cut down and exposed the entire third portion of the subclavian, ligating it at the outer part of the scalenus anticus and also at its axillary extremity. The communication was obliterated by ligating the vein laterally. During the operation I sawed through the inner two-fourths of the clavicle to allow of free dissection of the cicatricial tissue in the track of the bullet.

DR. J. RIDDLE GOFFE then read the paper of the evening, entitled

HYSTERECTOMY IN PUERPERAL SEPSIS, WITH REPORT OF A CASE.

(See page 103.)

DISCUSSION.

DR. W. GILL WYLIE: The subject is a most interesting one and is well covered by the paper. In many respects I agree with the author, while in others I differ from him. I will not touch upon the pathology of the subject, for I have made no personal investigation in this direction, but I will speak of my work in these cases. I have arrived at some fairly definite conclusions in the matter. For instance, I look upon a chill and fever in the parturient woman as puerperal fever, and treat the case as such unless it is very evident that the chill and rise of temperature are due to some other cause. I also believe that in nine cases out of ten the chill and fever are due to infection of the uterine cavity. In my experience I have found that this infection is usually superficial and mild; but it may become serious and in some cases fatal. I am of the opinion that many of the cases of what we call pyosalpinx are the result of sepsis after labor or abortion.

When I am called to see a parturient woman who has had a chill and rise of temperature I immediately explore the vagina and uterus and remove any material which should be removed. I am very careful in curetting these puerperal patients, especially if the sepsis is of eight or ten-days' standing, for it is very easy to puncture the uterine wall with the instrument. I generally use my finger or the dull curette. I then wash out the uterine cavity with a 1 to 100 or 1 to 60 solution of carbolic acid every hour for six consecutive hours. If the temperature does not fall within six hours I know that the septic poison has entered the uterine sinuses and reached the peritoneum and that peritonitis has begun. If it enters the veins and lymphatics and appears in the form of phlebitis, I simply watch it, for it is not necessarily fatal. If there is a center of pus formation at any point, in the pelvis or elsewhere, I open it and wash it out. But if the temperature falls after the uterine douche I know that the infection is a mild one and that the patient will soon be well. It is in the former class of cases that hysterectomy, performed before the septic peritonitis has fatally poisoned the patient, is indicated and these patients can be cured in no other way. If operation is delayed the woman dies because hysterectomy does no good when the surrounding tissues are involved. It is very difficult, however, to determine when septic peritonitis has begun. Last spring I saw a case of puerperal sepsis in which there was a laceration of the uterus which extended up into the broad ligament and peritoneum. I had been called in to do a hysterectomy as a last resort for the patient was thought to be dying of septic peritonitis. She had been curetted and her temperature had fallen some but had risen again. It was then 105° or 106° F., the pulse rapid, and the abdomen distended, but she did not present what I consider signs of a fatal peritonitis. I persuaded them to let me wash out the uterus. Her temperature came down and I cured the patient. I could narrate a number of such cases. The most important point in the treatment of these patients is to determine when septic peritonitis is beginning. Probably nineteen out of every twenty cases of puerperal sepsis are curable. We do not often see in the uterus the same kind of sepsis that we see in the appendix. In the latter the lack of drainage affords opportunity for a form of sepsis which is very virulent.

DR. ROBERT MILBANK: The paper is of unusual interest. In spite of its startling attractiveness it is to be hoped, however, that puerperal sepsis will not be allowed to reach the point at which operation is necessary. There are some cases in which hysterectomy offers the only chance of recovery, but these are the ones which have been allowed to go too far.

DR. A. M. JACOBUS: I have never had a case of puerperal sepsis in which hysterectomy was necessary and, therefore, cannot speak from personal experience on the question of the propriety of the operation in such cases. The case reported by the author is very interesting, but I have heard others report similar cases and the result is usually the same—the patient died, probably because of general infection and because operation was delayed too long.

The paper is so excellent that it cannot be criticised except in one particular. The author states that when a parturient patient has a chill and rise of temperature, he does not pay any attention to the common belief that either malaria, milk fever, etc., is the cause, but ascribes it to puerperal sepsis and curettes the uterus at once. I think this is wrong. I have seen many cases in which there was a chill, followed by fever, which were not due to any trouble in the uterus. I am quite sure that the author would not curette a uterus if it were not necessary but there are men of less experience than he who, on his dicta, will curette in every case after reading his paper. In many cases the engorged or inflamed breasts are responsible for the chill and fever. For example, I recall the case of a woman who was delivered of a dead child at the eighth month, everything coming away nicely. She had a chill on the third day after labor and this was solely due to the engorged condition of the breasts. There was a free supply of milk and the mammary bandage which had been applied had become loose. The fever was reduced by the administration of a dose of antipyrin and by massage of the breasts and the reapplication of the bandage. The woman recovered promptly without the uterus being curetted for any possible sepsis. In another case, in which there was a chill and rise of temperature on the third day after labor, I learned that the breasts had been left wet and exposed after nursing in a very cold room, with the result that a mastitis developed. No uterine sepsis existed. While I do not believe in milk fever as such, I do believe that often the chill in parturient women is due to congestion or inflammation of the breasts resulting from obstructed milk-ducts, sore nipples, incomplete nursing, etc.

Quite frequently there is some complication in the lungs, kidneys, or other organs, as well as attacks of malarial, eruptive, or other fevers, which cause chills and fever in puerperal women, and these possibilities should be thought of and excluded before jumping to the conclusion that sepsis has developed and that the uterus must be curetted at once. If the breasts are found in good condition and all other complications can be excluded, it is of course proper to look to the uterus and pelvic organs for the cause of the trouble. If the condition of the patient goes from bad to worse it may be best to remove the uterus, but I think that by making a posterior vaginal incision in order to drain the pelvis, and by removing the tubes and ovaries if they be septic, the uterus can generally be saved.

To illustrate the mistakes which are sometimes made by hasty treatment of the uterus, I would cite a case seen in consultation last winter. The woman had been prematurely delivered at the fifth month and I learned that the breasts had filled up and caused her much distress. On the third or fourth day she had a chill and her temperature went up, all due, as I believe, to the mammary condition. Her physician, although admitting that he was positive the uterus had been completely emptied, thought the woman was septic and douched the uterus with a 1 to 2000 solution of bichlorid of mercury two or three times a day, but paid no attention to the breasts. As the patient became worse he curetted and swabbed out the uterus with a fifty-per-cent. solution of chlorid of zinc, and continued the mercurial douches. As no improvement followed this operation, he repeated the zinc application. The result was that a general and local poisoning was set up and a so-called diphtheritic condition developed which nearly cost the patient her life on the seventh day after delivery. I persuaded him that the original chill and rise of temperature were probably due to the condition of the breasts and not to sepsis and that his very active uterine treatment had undoubtedly been the cause of the extremely critical condition of the patient. The woman was then given simple boric-acid vaginal douches morning and evening, followed by applications of bismuth to the eroded and swollen cervix uteri and vagina, the still distended and painful mammary glands were bandaged, and she recovered promptly.

DR. N. S. LEO: I agree with the last speaker in regard to his statement that the cause of fever in parturient patients is often to be found in the mammary glands. It should be borne in mind also that fever is sometimes due to a neurotic element. I think Dr. Wylie will recall a case which he saw with me in which the temperature ran up as high as 105° F. He advised washing out the uterus, and this was done for days and nights with the result that the woman's life was saved.

DR. J. BLAKE WHITE: It seems to me there is one point of diagnostic importance which should not be neglected in the discussion, namely, scanty if not actual suppression of the lochia as an indication of threatened sepsis. If such a condition occurs within three or more days after labor the danger of sepsis should not be overlooked. In such an emergency recourse must be had to intrauterine as well as vaginal douching with warm, mild carbolized solution, repeated at reasonably frequent intervals. This will often avert septic absorption and, in addition, lessen the probability of surgical interference being necessary. The radical measures described are but seldom required, comparatively speaking, and as shown by the author, rarely prove successful although the greatest skill be exercised because of the extension of the disease far beyond the local focus of its origin.

DR. R. A. MURRAY. As a rule operative interference in these cases is only successful when the disease is local.

If there is streptococcic infection more harm than good results from operation. Differentiation in diagnosis is a most important point. I am one of those who believe that after mammary and other sources of fever are excluded, the vulva, vagina, and uterus should be explored. In epidemics of puerperal fever which I have seen in hospitals the germs seemed to gain entrance through lacerations, and in many cases a diphtheritic membrane formed upon these raw surfaces. Removal of the uterus in such a case would be useless. In order to determine whether there is sepsis in the uterus, the finger should be passed into the cavity. If the os is patulous, the lining membrane rough, and a necrotic odor clings to the examining finger, the uterus should be curetted and douched clean. If then the patient's temperature does not subside, hysterectomy may be performed, but treatment at an early stage will do more good than operation will later.

DR. J. H. FRUITNIGHT: It should not be forgotten that there are two forms of septic infection, the sapremic and streptococcic. In the former the disease is generally the result of local infection from retained placental tissue or other *débris*, and under proper treatment the patients usually recover. If treated early by curettage and irrigation all these patients should get well, and it is in the early stage of this infection that the condition should be recognized. Streptococcic infection is always produced by contamination from without, and the practical conclusion is that one should not meddle with puerperal cases lest infection be introduced. A very glaring example of this is shown in a case which occurred in my practice. The patient had been delivered before my arrival and shortly afterward the placenta was expelled. Within twelve hours she had a chill and high temperature and died of puerperal fever in three days. I learned that prior to my arrival the nurse, who had recently attended patients with puerperal fever, had made several vaginal examinations and thus infected the patient. Operation would have done no good in this instance for the infection was not local but systemic. Extirpation of the uterus should be practised, if at all, before infection has advanced too far. Streptococcic cases are apt to terminate fatally.

DR. MURRAY: I believe Dr. Goffe was careful to say that the uterus should be examined before it is curetted. The term "meddlesome midwifery" is a bugbear in medicine, and what does it really mean? To some men I suppose it is "meddlesome midwifery" to examine a woman before delivery. In Dr. Fruitnight's case the mistake was to allow the nurse to examine the patient. It is absurd to say that the obstetrician should not examine a parturient woman. If his hands are clean enough to be put in the abdominal cavity, they certainly are clean enough to examine the uterine cavity. Ninety-nine times out of a hundred a chill after labor is due to the uterus; abscess of the breast is rare.

DR. GOFFE, in closing: I am glad that Dr. Wylie has been here to-night to give us the benefit of his experience with this disease. When I first left the Woman's Hospital it fell to my lot to see a great many of these cases and they made a deep impression upon me. Washing out the uterus was then extensively employed and many of the patients with mild attacks recovered under this treatment. I noticed that the serious and fatal cases were those which were neglected in the beginning, the attending physician having attributed the chill and fever to milk-fever or malaria. I decided then and there that the only safe way to treat these patients was to make a thorough examination of the genital tract and attack the disease in the uterus early. Of course it is understood that as a routine practice the mammary glands as well as the heart, lungs, and kidneys are first examined in every case. My effort has been to bring out in a decided manner the great fallacy with which so many practitioners quiet their apprehensions that milk-fever or malaria are to be generally credited with the rise of temperature in puerperal cases.

In regard to recovery after pyemia, I recall a case in which I confined a woman in the back room of a second-hand furniture store on Third avenue. The patient became septic and I curetted the uterus thoroughly, washed out and drained, but found it necessary to repeat the operation. Pyemic abscesses later developed in various parts of the body. I opened as many as five of these accumulations. Her system was thoroughly impregnated with pus, but she finally recovered.

It is true that probably a majority of these patients will get well if nothing is done because the infection in most of them is saprophytic. Dr. Wylie does not hesitate to say that he can cure nineteen out of every twenty of these patients by uterine irrigation if seen early. This is about the proportion of saprophytic to streptococcic cases of infection. I am inclined to think that when streptococcic infection is present the result is generally fatal. Dr. Fry of Washington who has made a careful study of forty-seven cases has found that streptococci were present in the lochia in but one instance. Dr. Williams of Baltimore also made investigations in this direction, and finds a larger proportion in which streptococci are not present, as do also some German investigators. I think the ratio will be found to be about one in thirty-five or forty.

In puerperal sepsis I believe in taking the disease in hand early, and I have never seen any bad results follow exploration of the uterus with the curette. In cases in which the disease progresses very rapidly, the infection is probably streptococcic and operation will do no good. The cases in which operation should be performed are those in which the disease is localized, in other words, not streptococcic. In the latter form of infection nothing can be done but to stimulate the patient. If Nature can form a wall to resist the invasion, the patient recovers. Fortunately, the great majority of these cases of puerperal sepsis are of the milder type and the patient will recover if she is given a fair chance; the chances are made better by curettage and douching of the uterus.

ORIGINAL ARTICLES.

THE TREATMENT OF HEADACHE.

BY JOSEPH COLLINS, M.D.,
OF NEW YORK;
PROFESSOR OF NERVOUS AND MENTAL DISEASES IN THE POST-GRADUATE MEDICAL SCHOOL; VISITING PHYSICIAN TO THE CITY HOSPITAL.

THERE is no symptom or disease whose cause demands more careful investigation that its relief may be encompassed than headache, and before we can speak legitimately of its treatment we must enter with some detail into its mode of occurrence, causation, and pathogenesis.

The term headache is an extremely comprehensive one. It may be applied properly to any form of pain in the head. To do so, however, is to confound unnecessarily manifestations of disease with individual disease. A radical and extremely important classification of headache is as follows: (1) Migraine: an individual disease like epilepsy; a neurosis of a degenerative type. (2) Neuralgia: including tic-douloureux, supra-orbital, occipital, and nuchal neuralgia. (3) Symptomatic headache: an indication of functional or organic disease, traumatic, accidental, or inherent. (4) Idiopathic headache: a rare form of cephalalgia which has no determinable association with organic or functional disease. Here only the third and fourth varieties are considered, as the first and second are properly considered under separate captions.

Headaches have been variously classified by different writers. Some believe that they are most safely interpreted when given topographical classification. Others contend that the character of the pain is the most reliable distinguishing feature, but the majority find it most satisfactory to classify headaches according to their causes and disease associations. Almost any form of classification may be made to serve a useful purpose. In my lectures I oftentimes refer to: (1) Headaches of early life, embracing the years up to puberty; (2) headaches of the adult; and (3) headaches of the senilium. Such a division has many advantages. It impresses particularly that the majority of headaches occurring in childhood are those known as reflex and the autotoxic, those of adult life are in the main symptoms of the functional neuroses and intoxications, while those of late adult life are usually expressions of arterial degenerations and the injurious actions of toxic agencies.

The two most important facts to keep in mind in endeavoring to interpret the significance of headache are, first, that it is an important symptom of a number of functional and organic diseases; and, second, that the location, character, and duration of the pain are oftentimes the means of suggesting and pointing its dependency.

Headache may be: 1. A symptom of functional nervous disease: neurasthenia, hysteria, epilepsy, and exophthalmic goiter.

2. A symptom of organic brain disease: meningitis, encephalitis, brain tumor, and brain abscess.

3. An indication of intoxication and infection. The sources of either of these may be endogenous or exogenous; that is, the intoxication or infection may arise from within the system, such as from diabetes, uremia, intestinal catarrh, etc., or it may be introduced from without, as by alcohol, nicotin, the metallic poisons, the malarial plasmodia, the acute infectious diseases, etc.

4. Due to disturbances and diseases of the circulatory system, such as accompanies the anemia of aortic stenosis and regurgitation, pulmonary emphysema and consolidation, general anemia and its different forms, and arterial sclerosis.

5. Due to causes that operate indirectly or reflexly to cause continued fatigue and exhaustion, such as from insufficiencies of the ocular muscles, irregularities in the refractive apparatus, irritation of the peripheral olfactory and trigeminal branches, or irritation of any of the great plexuses of nerves. Headaches of this variety are usually called reflex. When properly interpreted, there is no valid reason why this term should not be applied to them.

6. Due to trauma: traumatic headache. Headache may be the sequence of an injury that produces surgical conditions, such as wound of the scalp and bones, and it may follow trauma to the head which does not produce such injury. The explanation of the former variety does not seem a particularly difficult matter, and as for the latter, it is probably a variety of traumatic neurasthenia, occasionally pachymeningitis.

7. A local manifestation of rheumatic involvement of the epicranial and circumcranial tissues.

8. Finally, headache may be the expression of a pain habit, and to this the name habitual headache

is given. In other words, after the occurable headaches are parcelled out among these various diseases, there remain a small number that cannot be allotted to any one of them. It is more than probable that the headaches grouped under the heading of habitual headache are indicative in reality of a congenital or degenerative form of neurasthenia, and it is very questionable whether it should receive consideration apart from this group.

With this classification in mind, it becomes necessary to consider the characteristics of headache accompanying each of these diseases and classes of disease. By far the most important disease of which it is a symptom, because the most common, is neurasthenia. It is not at all improbable that nearly forty per cent. of all headaches of sufficient intensity and severity to demand treatment are a symptom of the neurasthenic state, in fact, we are justified in saying that all headaches of an intractable nature, and extending over a prolonged time are neurasthenic, with two exceptions: those due to brain tumor and to meningeal syphilis. The characteristics of neurasthenic headache are: (1) The location, on top of the head or encircling the head. (2) The character of the pain, a pressure feeling or drawing sensation. (3) The time of its occurrence, or better said, exacerbation, for it is usually present continually to a certain degree. The patient awakens with headache, and it continues more or less during the day, wearing off toward evening, being submerged by those pleasures or indulgences that increase general neural tone. Its disappearance coincides with the feeling of moderate well being which most neurasthenics have in the evening. (4) The fact that it is made worse by fatigue, mentation, and excitement. Sufferers with this form of headache are extremely voluble concerning their ailments. They harp on the different manifestations of their infirmity, and have a decided inclination to hypochondriasis. Such patients ordinarily present the customary slight physical accompaniments of neurasthenia: relaxed tonus of the skin, fine tremor of the extremities, particularly of the hands, excitable but easily exhausted muscle and tendon reflexes, such as knee-jerks, and evidences of disordered digestion, impaired assimilation, and constipation.

Hysterical headaches are, compared with the variety just considered, very uncommon. Their diagnosis rests first upon the nature and seat of the pain, the classical form being that of a nail driven into the head, the seat being at the supreme vertex, and its association with the corporal and mental stigmata of this neurosis. The more important of these stigmata are: hyperesthesia or anesthesia in the sensory sphere and special senses; hysterical tremors, spasms, or contractures; hysterical palsies; limitations of the intellectual sphere, obsessions, compulsions, and defective inhibition.

Headache accompanying the neurosis known as epilepsy is an extremely important symptom. Temporally, it may be preconvulsive, post-convulsive, or the convulsion equivalent. It is characterized by unheralded onset, by extreme intensity, and by its abrupt termination, followed by a period of great mental and physical exhaustion. The preconvulsive epileptic headache may be brief and of the nature of an aura. In such case it is followed by a convulsion, except in instances in which prompt and vigorous measures are taken to thwart the explosion. It is particularly those cases in which the headache is the equivalent of a convulsive attack that are followed by great prostration. The post-convulsive headaches are characterized by a feeling of soreness in the head, undefinable and unlocalized, and by more or less mental confusion. Both of these disappear as the headache passes off. All cases of idiopathic headache occurring in childhood and early adult life having some or all of the characteristics just enumerated, should be investigated most carefully and assidulously to determine whether or not they belong to this category.

Headache attending exophthalmic goiter is in its nature of two kinds, toxic and neurasthenic. The latter element is, I believe, the more important one. The entire symptom complex of exophthalmic goiter is practically that of a profound state of neurasthenia. Whether this neurasthenic condition is primarily or secondarily toxic does not here concern us. The headache which accompanies this disorder is characterized by its vertical and frontal location, by its throbbing, pulsating character, and by its amenability to measures that contribute to general repose and to slowness of the heart's action. It is aggravated by anything that produces the antithesis of these. Its diagnosis offers but little difficulty, save in those cases in which the headache is a precursor of the pathognomonic accompaniments of this disorder.

The most important organic disease of the brain and its coverings attended by headache, is tumor, and it matters not very much what the nature of this neoplasm may be, although its location stands in some relationship to the nature and seat of the pain. The character of the pain of brain tumor is a very variable quantity. In one case it is of a boring, gnawing character, in another of a distending, skull-splitting kind, while in a third case it is a dull, consciousness benumbing ache. In all cases, persistence is one of its most striking characteristics, especially in the beginning of the dis-

ease. Later on, when the sensorium becomes so benumbed from intraventricular distention that pain does not enter as a qualé of consciousness the patient ceases to complain. It is exacerbated by anything that jars the head, such as tapping, coughing, sneezing, and bodily agitation, and by everything that increases blood pressure or a determination of blood to the head. The pain is local or diffuse, and rarely does it correspond to the seat of the tumor or indicate its location. Tumor of the cerebellum, however, almost invariably is accompanied by headache, located in the occiput or the forehead. The occurrence of headache of the nature above described can only suggest the existence of brain tumor; its association with other symptoms makes the diagnosis.

The headache of brain abscess is not particularly characteristic. It may be said, however, that it is persistent; severer during the early night than the early day; increased by coughing, jarring, and stooping; entirely unamenable to any medication, and generally accompanied by corresponding and increasing mental obscuration. It is not infrequently localized, particularly when the brain abscess is of otitic origin, but in many cases the patient locates the pain remote from the seat of the disease. It is diagnostically significant only when associated with the known etiologic and symptomatic features of the disease.

The headaches of acquired hydrocephalus, of encephalitis, and of disease of the cranial sinuses have nothing pathognomonic about them. They assume importance only when associated with other and more significant symptoms, such as vertigo, vomiting, convulsions, and paralysis, for hydrocephalus; the manifestations of inflammatory phenomena, for encephalitis; and the accompaniments of an infection or marasmic condition, for sinus thrombosis. The headache accompanying the latter disease has, however, almost invariably a local seat which corresponds to the place of inflammation.

The headaches of meningitis cannot be easily and satisfactorily disposed of in a few words. Every practitioner knows that all the varieties of leptomeningitis are attended by severe headache, and that such pain has a number of distinguishing features and associations. It is of acute onset, of a boring, unendurable character, which causes the sufferer to shriek out in his sleeping as well as in his waking moments. It embraces the entire head, shooting from one location to another, and it is accompanied by such diagnostic symptoms as nuchal rigidity, localized and general spasm, pupillary inequalities, temperature, and finally paralytic phenomena. In tuberculous meningitis the headache is not so intense as in some of the other forms of leptomeningitis, and it is oftentimes localized in the occipital and cervical regions, while the pain of purulent meningitis is more often frontal than occipital.

The common forms of pachymeningitis are those due to syphilis and to trauma. They are both accompanied by intense headache, which is due to compression of the dural nerves. Both tradition and experience have it that the headache of syphilitic pachymeningitis is apt to be localized to a very small area or to involve the entire occipital or upper cervical region. The pain is not continuous, is sometimes worse at night, and is exacerbated by intellectual effort and by factors that increase the intracranial blood-supply. Headache of pachymeningitis cannot be distinguished by a consideration of this symptom alone from cephalic pain caused by such a condition as enlargement of the pituitary gland in acromegaly.

The headaches of circulatory disorders are not so common numerically as one might be led to suppose from reading the chapters on these diseases in the text-books. A decade or two ago cerebral anemia and hyperemia received a disproportionate and undeserved amount of attention, both from the neurologist and the general practitioner. Their occurrence, it was thought, was quite an every-day affair, and a fanciful, intricate symptomatic superstructure was erected to encompass their subjective and objective accompaniments. To-day it is well-nigh universally conceded that neither of these conditions occurs as an individual state apart from pathological conditions in other parts of the body. Undoubtedly, a condition of cerebral anemia is a common dependancy of aortic stenosis, and of mitral regurgitation when the latter goes uncompensated. On the other hand, pulmonary emphysema, pulmonary atelectasis, a prolonged paroxysm of pertussis or asthma, disease of the right heart, may and do produce difficulty of egress of the return circulation, and thus a state of hyperemia, but no one will be likely to contend that the cerebral anemia or hyperemia thus induced is an individual disorder. On the contrary, these factors are integers in the pathologic entity. It is very possible that prolonged and intense excitement, such as that of acute mania, the injection of large quantities of cardiac and vascular stimulant, and possibly great physical effort, may determine a disproportionate amount of blood within the cranium, but the facilities for adaptation provided by the enormous lymph-cisterns soon equalize this, and prevent it from becoming sufficiently permanent to constitute the basis of symptoms.

Headache is a common accompaniment of symptomatic cerebral hyperemia and anemia, and of general anemia. Its indicativeness is suggested by association with other symptoms. When we come to consider the diagnostic value of the locality of cephalic pain, it will be seen that headaches of general anemia are usually confined to the forehead and eyes, and associated with a more or less sharply defined area of occipital pressure. They are in reality a form of neuralgia in the majority of instances conditioned by want of nourishing blood-supply to the trigeminal and occipital nerves. The pain of anemic headaches is a variable quantity, but sometimes it is of almost intolerable severity. The patient is rarely completely free from it. Its character is that of a heavy pressing sensation, but at the periods of its exacerbation it is throbbing, and relieved by external pressure. The headaches that accompany chlorosis, progressive pernicious anemia, and leucemia have no striking characteristics that differentiate them from general anemic headaches. The headaches attending leucemia are not so intolerable, notwithstanding the gravity of this disease, as those of general anemia and chlorosis.

Headache due to the organic disease of the blood-vessels, arterial sclerosis, is associated with other very significant symptoms, a consideration of which readily makes the diagnosis. These are vertigo, slight syncopal attacks, disorder of the nutritional equilibrium, changes in the blood-vessels, detectible to the touch and to the eye, slight mental deterioration, and general lowered vitality. The headache is usually of a throbbing character, not infrequently associated with sounds and noises in the ear, a sensation as if the head were being drawn forcibly backward, and with a feeling of portentous dread. It is increased by everything that increases blood-pressure and by anything that diminishes vital force.

The headaches that are grouped under the caption of reflex headaches are a very important class, not so much because of their frequency, but because of the fact that they are extremely amenable to treatment if interpreted early; and extremely sluggish to any therapeutic response if they have been allowed to go on for a long time. In other words, if they are attacked before a headache habit is formed, remedying the conditions on which they are dependent suffices to cure in the vast majority of cases. If they are not such orthopedic measures only alleviate, but do not cure. By far the commonest cause of reflex headache is improperly implanted or innervated musculature of the eyes and defect in the refractive media. The headache which these two conditions cause is in reality an exhaustion headache. If it continues for a long time it is almost impossible to differentiate it from neurasthenic headache. If some of the muscles of the eyes are so deficient congenitally or as the result of disease that a strain is continually put upon other muscles in order to cause normal binocular vision, or if the cornea and crystalline lens are so ill prepared for their function that they do not focus parallel rays of light immediately on the retina save by the effort of muscles to change their radii of curvature, then the strain thus caused induces, after a time, a state of profound neural exhaustion which is manifest by headache. This headache has usually the following characteristics: It is limited to the forehead or to a very circumscribed spot in the occiput; it is made worse by use of the eyes, and it is remedied by resting the eyes and by anything that temporarily paralyzes accommodation. It is never present on arising in the morning and one of its most striking features is that it is strictly sabbatarian. Fortunately ordinary routine examination is often all that is necessary to show the shortcomings of the peripheral ocular apparatus and to indicate the necessary measures to overcome it.

The next most common variety of reflex headache is from the pelvic organs, and this variety of headache is peculiarly an exhaustion headache. It is not met with nowadays with one-half the frequency that it was in those times when it was the vogue to tinker with the generative organs of the female. Reflex-uterine headache has been expiated at the shrine of the modern, non-meddlesome gynecologist. Headache associated with posterior displacements of the uterus and cervical lacerations—two important causes of uterine headache—is usually neuralgic in character, its favorite location being in the occiput. Such cephalalgia is often associated with tenderness on pressure in the cervical region and with "weak back."

Judging from my own experience as well as from the statements of rhinologists, headaches associated with disease of the nasal passages without involvement of the frontal sinuses and ethmoiditis is not very common, although some nasal specialists would have us believe that more than three-fourths of all headaches, including migraine, are due to disorder of the nose. The intemperateness of such a claim indicates that the one who makes it has his visual horizon limited to the field of the nasal speculum. Nasal headaches are usually due to irritation of the branches of the trigeminal nerve, caused by swelling of the mucous membrane and deformity and hypertrophy of the nasal walls. It is frontal in location, usually above the root of the nose, of a dull, boring character, oftentimes relieved by gentle frontal pressure and temporarily ameliorated by sniffing pungent

aromatic substances. It is more or less continuous, but very liable to paroxysmal exacerbations. It is worse in the morning immediately on arising and usually it ameliorates materially after the patient has had his bath, breakfast, and any other indulgences that improve the general circulation and temporarily invigorate. If dependent upon ethmoiditis or disease of the frontal sinus the accompaniment of swelling on the orbital surfaces of the nose and the discharge are important. Headaches that are reflex from the ear are very uncommon, and when they occur they have no distinguishing features, save the location in the mastoid and temporal regions.

Reflex headache from other causes, such as from the sexual organs of the male, are oftentimes subjective states of consciousness on the part of the diagnostician.

Headaches of toxic origin, using the word toxic to cover endogenous and exogenous sources, have little in their localization or character to distinguish them from other headaches. The fact that they occur in persons who use tobacco, alcohol, tea, drugs, etc., and in those who are exposed to the absorption of lead, carbon dioxid, mercury, phosphorus, etc., leads one to suspect their true origin, while the presence of other more characteristic features of such intoxication attests the diagnosis. Like the headache of auto-toxemia, particularly those associated with intestinal catarrh, they are oftenest located in the front of the head and described as heavy-pressure feelings, though sometimes they are of a throbbing nature made worse by anything that disturbs the vascular circulation. The metallic poisons, arsenic and iodin, produce a very characteristic feeling of suffusion in the forehead, while lead, on the other hand, frequently causes a diffuse pain extending over the entire cranium, but occasionally confined to one spot in the distribution of the trigeminal nerve. More than a few varieties of headaches are associated with disorder of the digestive apparatus. Four factors enter ordinarily into their production: (1) The absorption into the system of products of incomplete digestion and assimilation, which, in the process of metabolism, principally in the liver, result in the formation of alkaloidal substances having toxic properties. (2) Diminution of blood-pressure apart from that produced by the action of the resulting leucomains and ptomains. (3) General and local anemia, which is almost invariably an accompaniment of indigestion; and (4) reflexly, from distention of the gastric and intestinal walls. These headaches are usually frontal, often immediately above the eyebrows, and the patient describes the pain as a confused, apathetic feeling, with exacerbations of sharp pain. It is almost invariably worse in the morning and is frequently relieved by purgation or by vomiting. The diagnosis is to be made from the condition of the patient's breath and tongue, from the accompanying phenomena of disordered stomachic and intestinal digestion, and finally, if necessary, by the administration of a test meal, its removal and analysis. Headache that accompanies an attack of acute indigestion varies in its localization, character, and intensity with each patient. In my experience the commonest location is the anterior one-half of the head; the pain is of a throbbing character synchronous with the heart-beat and it is made very much worse by physical activity and especially by sudden changes in the position of the body. It is often associated with a sensation of a collar or band bound tightly around the neck; with flushing of the face and slight injection of the conjunctiva.

A form of intestinal trouble which sometimes produces headache in children is the presence of parasites. The diagnosis is to be made only when the parasites are found in the stools. Headache is the commonest forerunner of the infectious diseases, but with the exception of a few, such as syphilis, malaria, typhoid fever, influenza, and epidemic cerebrospinal meningitis, they have no distinguishing features. Headache is an extremely important accompaniment of syphilitic disease, and it shows itself either during the period of eruption or as a symptom of tertiary manifestations. The headache of the eruptive period may be distributed over the entire head, or limited to the occiput. Very rarely does it reveal itself as hemicrania. It is not distinguished so much by its location as it is by the fact that it occurs usually at night, or is very much worse at this time. During the day it diminishes in severity or disappears. It is not infrequently accompanied by manifestations of frontal or parietal periostitis, discernible to the sight and to the touch. Headache accompanying the later stages of syphilis is perhaps of even more frequent occurrence. Although it has a decided predilection to be worse at night, it is more readily recognized by its association with vertigo, slight dementia, paresis, or spasm of the musculature of the cranial nerves, and by other irritative and paralytic phenomena which pursue an extraordinary course than by any other feature.

It was formerly thought that headache of malarial infection was usually a neuralgic-like pain over the eyebrows, having a striking periodicity, but the recent experiences of our citizen soldiers in the tropics have shown that at least the headaches of acute malarial infection have no diagnostic features. It is quite impossible to differentiate them from those of typhoid fever. It is probably

true that the profound anemia which is such a striking accompaniment of chronic malarial poisoning, expresses itself oftenest in the nervous system by a neuralgia of the supra-orbital nerve. But nowadays one would not be likely to make the diagnosis of malaria without having discovered some form of plasmodium in the blood.

The headache of epidemic cerebrospinal meningitis is so characteristic, both in its location and intensity, that it requires no detailed description.

(To be continued.)

THE CARE AND MANAGEMENT OF THE PREGNANT WOMAN.[1]

BY B. M. HYPES, M.D.,
OF ST. LOUIS, MO.

PREGNANCY is a natural physiological function. In a state of perfect health it should be accomplished without disease or suffering. But, as a matter of fact, so generally is pregnancy associated with discomfort and illness, that a celebrated French obstetrician has called it "a nine-months' disease." Nor is it to be wondered at that women should suffer in this condition. Under no other circumstances do such extensive changes in organs and functions take place in so short a time. In this disturbed and hypersensitive condition of mind and body, how readily the overworked organs pass the boundary line from exaggerated physiologic function to a pathologic condition, and how often do we find the latent or mild forms of disease, especially of the kidneys, heart, and nervous system, slowly and insiduously develop most dangerous and uncontrollable symptoms? But proper care and management will lessen if not entirely relieve the many discomforts of pregnancy, and timely medical advice will generally ward off disease and prevent it assuming a dangerous character. By skilled attention during pregnancy not only will gestation be more successully accomplished, but the woman will be so strengthened and fortified for the demands of labor that its difficulties and fatalities will be markedly lessened.

My observation and experience leads me to think that this is a field in obstetric practice that needs cultivation by us as physicians. The laity, too, need education on the importance of caring for a woman throughout pregnancy, not only for her own sake, but, as Plato has expressed it, "that she may successfully bear children to the State." We may, very properly, go still further back and demand that the girls, the future mothers of the country, should receive such care, training, and education as will properly fit them for this noble and responsible duty. They should be taught the simpler laws of hygiene—how to eat, to exercise, to care for their bodies and minds in order that they may develop into healthy women. The hygienic surroundings of every school, factory, store, and workshop should be supervised in order to protect them from injury and abuse.

In viewing this subject from a practical standpoint the inquiry naturally arises, In what does the care of a pregnant women consist? Can such a practical course of management be adopted that it will meet with the approbation of the profession and become a feature of our routine practice?

The care of the pregnant woman should begin with conception. The laity ought to be taught that whenever a woman finds herself pregnant she should at once select an attendant physician and place herself under his care. This she does, not to be "dosed" with medicine, but that she may receive advice and instruction as to the duties and dangers of pregnancy, and that her physician may gain such knowledge of her as will enable him to successfully manage both her pregnancy and labor. The physician should thoroughly familiarize himself with her personal and family history, with all difficulties in previous labors, with all peculiarities and idiosyncrasies, so that he may fit his instructions and medication to her individual case. He should then advise her in regard to her food, its character, and when and how it should be taken; as to bathing, and how performed; as to proper clothing, and mode of wearing it; as to the danger of constipation, and means of prevention; as to bad effects of coitus, and the necessity of its control; as to the care of the breasts, so as to fit them for the new function of lactation, and of the necessity, especially after the sixth month, of frequent examinations of her urine.

She should be advised as to certain danger signals, and should be thoroughly impressed with the necessity of informing him at once of any abdominal pains, of any flow of blood from the vagina, of persistent headache or dizziness, of any epigastric pain, of nausea and vomiting late in pregnancy, and of the first appearance of edema. She should be informed of the danger of lifting heavy weights, ot reaching, of overexertion and of fatigue, of riding over rough roads, and of taking long railroad journeys. At the seventh month he should make a careful physical examination, both external and vaginal, to determine the presentation and position of the child, and to note any abnormalities which might seriously complicate labor. Pelvimetry must be regarded as a most necessary part of this examination.

[1] Read before the Missouri State Medical Association at Kansas City, Mo., 1898.

To this scheme of the management of pregnancy I apprehend two objections: First, that it is unnecessary, as a pregnant woman seldom needs medical attention; and, second, that it is impracticable. As to the first, let me reply that the same may be said of labor. In a large percentage of confinements the physician need merely stand by and Nature will do the work. But his presence is, nevertheless, demanded to attend the natural as well as the difficult cases that he may watch for dangerous delay to mother or child; to protect the perineum; to see that the secundines are all expelled; to prevent postpartum hemorrhage; to assist when Nature fails; in short, to prevent all evil consequences to his patients. Likewise, as a preventive measure, should this close attention to the pregnant woman serve to instruct her in hygienic laws; to impress upon her the importance of watching for the first signs of disease, so that it may be checked in its incipiency; to correct abnormalities when possible. Thus forearmed, the physician will anticipate and be prepared to treat most successfully emergencies that may arise during labor, and so be able to lessen the unduly large mortality of childbirth. Puerperal eclampsia, that dire calamity of child-bearing, is a preventable disease, and will almost disappear from the records when women are properly cared for during pregnancy. The brilliant obstetrical and surgical records of the maternity hospitals are greatly due to the fact that women are under observation and the abnormalities diagnosticated during pregnancy, and because the most favorable time for operations is taken advantage of.

As to the second question, Is it practicable? I desire to answer most positively *Yes*. For several years past this has been my practice, and rarely do I attend labor cases except in consultation without having had the patient under previous observation. I make it a practice to visit the patient frequently; to make frequent examinations of the urine; to measure the pelvis of all new patients; to note the presentation and other conditions of the child in utero; to learn the patient's history, and to fortify her against probable or possible difficulties.

In conclusion, I hope that every member of this Society who attends pregnant women will consider thoughtfully the suggestions of this paper, and if in the slightest degree the practice of obstetrics shall be made more successful, the object of the writer will have been attained.

Yale Medical School Changes.—Dr. Benjamin Moore of London has been appointed professor of physiology in place of Dr. Graham Lusk, and Professor Allen R. Defendorf has been appointed Lecturer on Insanity.

THE USES AND DANGERS OF INVESTIGATION IN PUBLIC AND PRIVATE CHARITIES.[1]

BY JOSEPHINE SHAW LOWELL,
OF NEW YORK;
MEMBER OF THE NEW YORK STATE BOARD OF CHARITIES.

THE uses of investigation in the work of "charity" are obvious. The first use is so obvious that it seems almost needless to mention it, especially to an audience of medical men. It would be as reasonable to ask "what is the use of a diagnosis?" as to ask "what is the use of an investigation?" The use is to *find out what is the matter*, because if we do not know, we cannot do any good at all. There is always a cause for the distress of those who come asking for help, and we cannot really help them, unless we know what the cause is, and at least *try* to remove it. And yet there are many people who are benevolent and who want to help, but who go on blindly without getting any thorough knowledge of the actual condition of those who come to them. To take the commonest and perhaps most natural form of this error as an example: Many benevolent people know only the *women* of the families they are trying to help. They want to elevate their physical and moral condition, but how can they elevate them if they are only brought in contact with one-half of each family, leaving out of account the person whose duty it is to do for his wife and children what they are undertaking to do for them? How do they know that the husband of the woman they are supporting is not at work? How do they know that he is not spending all he can earn and all he ought to devote to his family at the corner grog-shop? How do they really know anything of the family, if they ignore the existence of the head of it, of the man responsible before God and man for its well-being?

The second use of investigation is that it prevents the growth of great moral evils, for its absence tends to the speedy demoralization of decent people. What I mean will be perfectly clear to you if you will consider what a terrible temptation is presented to unhappy people in distress, if they can go round from church to church, from person to person, repeating a story of misery and distress, obtaining from each person twenty-five cents, fifty cents, or a dollar, and sure that not one of them will ever make any real inquiry into the facts, sure that none of them will ever know that the others are giving also. Let me give an illustration. A decent, but improvident man dies and is buried, by his club, or his friends, or by "charity," and the newly made widow is left with a number of young children dependent upon her for support and care. She must act the part of

[1] Read before the New York Medical League at its meeting at the Academy of Medicine, January 20, 1899.

both father and mother, and her state is pitiful indeed. She has no relations and she turns naturally to the members of her church. She touches the sympathy of those she applies to, but no one feels any sense of responsibility, no one feels obliged to make an investigation, no one recognizes the great danger with which the woman and her children are confronted, the danger of becoming degraded and corrupted into beggars and liars, and so every one does just enough to quiet his own sense of pity, gives $1, or $5, or $10, according to the more or less touching nature of the woman's story, and then dismisses it from his mind. The poor woman, truly in distress, finds that the recital of her sufferings brings in a sum of money which ten days of hard work would not earn, and, most naturally, she is content, when the proceeds of her first appeal are spent, to make another. Why should she not? It would be *stupid* to seek for washing or scrubbing at a dollar and a half a day, when she can get $5 or $10 in an hour by telling the truth to two or three kind-hearted people. She finds, however, that as the truth becomes less sad, as her loss affects her less, and the urgency of her appeal is diminished, that the proceeds are diminished also and therefore she does not confine herself to the truth. She colors and exaggerates; she takes one or two of her children with her to help her emphasize the story; she teaches them to cheat and to lie, and she finds that it *pays* and thus she is tempted into a life of deceit, and her children follow in her path, and it is the neglect and carelessness of *benevolent* people who will not take the trouble to find out the real condition of the family and to make and carry out a plan by which they can be rendered self-supporting, that brings them to this horrible condition.

But investigation is of use not only in preventing the demoralization of decent people, but in the detection of those who have become expert deceivers —and this is important because it too has a bearing on public morals. It would certainly not be worth while to take any trouble to save the sums which rich people waste on ill-considered alms, but it is worth while to take a great deal of trouble to save the poor from the temptations which beset them when they see the rewards reaped by successful knavery. It would not be worth while to pursue imposters and punish frauds were the only advantage gained the saving of money to extravagant and selfish people—but it is worth while to prove that lying and cheating are not an easier and pleasanter way to get a livelihood than by working.

Let me sum up then the uses of investigation I have named. 1st. Investigation as the only means of learning how to really help those in distress. 2d. It prevents the demoralization of decent people by removing the temptations to beggary. 3d. By the discovery of fraud investigation makes a life of deceit less attractive.

But to offset these uses I must now turn to the dangers of investigation, for it is a dangerous tool which may wound cruelly, if used without thought and care. We had in New York, in the hard times of 1893-4, a most painful experience in this regard. The very word "Investigation" seemed then to have been made a sort of shibboleth by the newspapers, and in too many cases by the ministers also, and to every remonstrance against methods of relief-giving which were injurious to the character of those who were supposed to be helped by them, and cruel in their entire disregard of their comfort, happiness, moral and physical well-being, it seemed to be considered a sufficient answer to say: "All the cases have been thoroughly investigated." And it was evidently thought that this answer ought to be entirely satisfactory even though the investigations were made not for the purpose of furnishing guidance and knowledge for a long course of "treatment" by which weak wills might be strengthened, bad habits be cured and independence developed, but in order that a ticket might be given which would entitle the man or woman to receive some old clothes, or some groceries after a long, weary waiting in the street in the midst of a crowd of miserable people whose poverty and beggary were published to every passer-by.

Think of the destruction of self-respect, the crushing out of all shame, the fostering of every unworthy feeling which such an experience must result in, and yet this too often was what "investigations" were made for during that winter in New York, and both newspapers and ministers seemed all alike to accept the theory that so long as the people were found to be "worthy" it mattered not how much their characters were injured, provided only their bodies were fed, or, in other words, how thoughtlessly the work of making them "unworthy" was carried on.

Since such dreadful results can come from a failure to recognize the true uses and limits of investigation, and since they have arisen from a misunderstanding of them, I believe it to be our duty to declare that investigation, in itself, is *bad;* that the only excuse for trespassing upon the privacy of other human beings, for trying to learn facts in their lives which they prefer should not be known, for seeking to discover the weak spots in their characters, for trying to find out what pitiful personal reason there is for the distress in which they are, for seeking to learn what sorrows their nearest and dearest have brought upon them—the only justification, I say, for doing all these painful things, which are too

often included in the single word "investigation," is that the person in distress has asked you to help him, and that you *mean* to help him, *to help* HIS SOUL and not only to feed his miserable body, and that you cannot help him unless you do know all about him. Everything that is said against investigation by its critics is true, and no one feels the truth of it more strongly than we who believe in its necessity. We know that it is a necessary *evil*, and we try to make it as little evil as we can, and we only justify it, as I have said, because it is the preliminary to the real work of helping those in distress by careful, conscientious, patient, painstaking personal work, just as the torture of a sick man by the physician's examination can be justified only for the same reason, that he has to know what the matter is before he can take one step in trying to cure the man.

The necessary invasion of the privacy of the lives of other men and women is one of the great evils of "investigation"—it is a sort of outrage upon the dignity of a human soul, and ought not to be undertaken if the object of the investigation is not a nobler one than the mere feeding of the body, for the soul should not be sacrificed to the body—"What will it profit a man if he gain the whole world and lose his own soul?"

In all such work the best rule is to "do unto others as ye would that they should do unto you" and to try to realize what would be the effect on one's self of the contemplated action, and also to remember that, the object being to help, one must do as little harm as possible in the process of helping.

The thorough investigation and study of the character and needs of persons who ask for help and the attempt to educate and develop them, even by means which may not be very pleasant to them, is sometimes called "the new charity," but it seems to me it is only obedience to the old teaching I have quoted. For, after all, would we not each one of us prefer to be dealt with, were we in the place of an applicant for relief, in such a manner as would elevate us morally and physically? Would any one of us deliberately choose such treatment from another as would undermine our moral strength and power, even though it should save us from suffering?

Does not God deal with us in what we choose to call "the new way"? Are we not driven by necessity to exert ourselves, do we not suffer the results of our own acts, can we by any means escape from the consequences of our sins and mistakes? And is not the common way of relief-giving and what we call "charity" so far as possible an *interference* with God's education of his people? We relieve men and women of the necessity of working, we reward them for idleness, we encourage them in vice, we take their children from them when they are young and troublesome and care for them in institutions, and when they are old enough to labor we give them back to those who claim a parent's rights, although they never discharged a parent's duties. We tempt our poor weak brothers and sisters to give up the struggle which has been appointed to make them strong and brave. We accept every invention they use to work upon our feelings; we lead them to lie to us and to become cheats.

CLINICAL LECTURE.

EPITHELIOMA OF THE PENIS.[1]

By WILLIAM L. RODMAN, M.D.,
OF PHILADELPHIA;
PROFESSOR OF THE PRINCIPLES OF SURGERY AND CLINICAL SURGERY IN THE MEDICO-CHIRURGICAL COLLEGE; FORMERLY PROFESSOR OF SURGERY AND OF CLINICAL SURGERY IN THE KENTUCKY SCHOOL OF MEDICINE, LOUISVILLE, KENTUCKY.

THIS patient, Mr. B., aged about seventy years, has an epithelioma of the penis, the exact duration of which is uncertain but the history seemingly shows that it was first noticed three years ago. He has been treated in the genito-urinary department, caustics having been applied on several occasions. While the growth was apparently destroyed by caustics, it promptly returned, since which time there has been intense pain in the glans penis, and great difficulty in micturition. For these reasons the patient has consented that his penis be amputated, which I have told him offers the best chance of ultimate cure and promises speedy relief from his suffering.

Epithelioma of the penis sometimes runs a chronic course; such a course, however, is rare. It usually destroys life in 3 to 3½ years; this is about the average duration. The disease may begin in the prepuce, on the glans, or at the junction of the prepuce and glans; it may begin as a wart, a crack, or a distinct ulcerative condition. There may or may not be pain; usually, however, there is pain early in the history of the disease. If, as occasionally happens, the growth is situated well forward on the prepuce, it may be entirely removed by circumcision, though I have never seen a case in which such treatment would be applicable. I believe the only methods of treatment to be considered are: (1) by the knife, (2) the application of caustics, and (3) the use of the galvanocautery. I have seen one excellent result from the application of caustics. In that case the patient declined the use of the knife, but readily consented to the application of escharotics. The man has done uninterruptedly well for 2½ years, and has about reached the time when it may be said with comparative safety that he is cured. Most recurrences take place within twelve months, some as late as 2 or 2½ years, and in exceptional cases later than 3 years, but it may be stated that

[1] A clinical lecture delivered at the Kentucky School of Medicine Hospital.

if a patient operated upon for malignant disease in any situation passes 3 years without recurrence he is practically safe, as there are not many chances that the disease will recur.

Epithelioma of the penis is most common in elderly men. It is rare under forty-five years, and yet I have seen two such cases, one in a man aged forty-one, and in another aged thirty-five. The greatest number of cases occur in men between fifty and seventy years of age.

While the galvanocautery has been used in many instances for the removal of epithelioma of the penis, and is still advocated by some surgeons, its use is not to be advised. Statistics show that cutting operations by cold instruments are preferable to operations by heated instruments. This at first blush is perhaps just the opposite of what might be expected. It might be reasoned *a priori* that the cautery would materially lessen hemorrhage, a danger in the operation which is greatly magnified by some authorities. One reason why the mortality after the use of hot instruments will be greater than after that of cold instruments is the fact that pyemia, erysipelas, and septicemia are more likely to follow the use of the former. This may be difficult to understand at first, yet it is reasonable when viewed from the proper standpoint. When hot instruments are used blood-clots and tissues are necessarily left to decompose in erectile structures where absorption perhaps takes place more rapidly than in any other situation of the body. It must be remembered that following the use of hot instruments in this operation there is left in erectile tissue a slough which cannot be gotten rid of on account of the crust above, thus furnishing suitable conditions for the development and growth of pyogenic organisms. For the reason that absorption of these septic products rapidly takes place, because of the abundance of absorbent vessels in this peculiar tissue, it is not unreasonable to expect a certain number of deaths from pyemia, septicemia, erysipelas, etc. The mortality following the use of hot intruments in this operation is from three to five times as great, according to the statistics of Butlin and other excellent authorities, as when the knife is used. The cardinal feature in amputating the penis is to leave the urethra longer than the corpora cavernosa, otherwise the urethra will curl up and retract beyond the end of the stump and give the patient trouble when he begins passing urine in the natural way.

In this instance the method of procedure will be that devised by Jacobson. A flap will be made from the dorsum of the penis, the incisions being carried down on each side very much as would be done in amputating at the lower third of the thigh. The dorsal vessels of the penis, which will be contained in the flap will then be tied, and a catheter will be introduced into the urethra to outline the corpus spongiosum. A straight bistoury will then be inserted so as to just miss the corpus spongiosum and not cut too far into the corpora cavernosa, between them if possible, on a level with the retracted flap. It will be carried downward about one-half to three-quarters of an inch, and then made to cut obliquely outward so as to leave the urethra much longer than the corpora cavernosa. Re-inserting the knife at the same point the corpora cavernosa will be cut vertically, thus making two skin flaps. The arteries of the corpora cavernosa, also one coming from the bulb of the corpus spongiosum, must then be ligated. The urethra will be pulled forward, a hole will be made in the upper flap, the urethra brought into this split into halves and stitched in position. The penis will thus be entirely covered by a skin flap which will materially shorten convalescence and give the patient less pain because urine will pass over the skin rather than over the exposed corpora cavernosa. A catheter will be introduced into the bladder and to this will be attached another Nelaton catheter so as to carry the urine away from the dressing. After the primary dressing has been removed, nothing but iodoform will be used.

When this patient was first seen by me there were a number of enlarged glands in the inguinal region. These glands have since decreased in size, and I think the enlargement was due to some cause other than the epithelioma, probably cauterization of the sore on the penis. It is easily understood how these glands may become enlarged from irritation about the penis whether or not the irritation be chemical, gonorrheal, chancroidal, or syphilitic. It seems that the glandular enlargement in this case was sympathetic, and not due to metastases or malignant deposit. Had it been thought due to metastasis the glands would have been cut down upon and removed. The patient will be carefully watched and if it seems wise at the end of a week or ten days, when he has recovered from the present operation, all the inguinal glands will be removed.

As to the mortality following amputation of the penis, a conservative estimate would be two or three per cent. Some authorities place it as high as five per cent. or higher. Death occurs from erysipelas, pyemia, or septicemia. It is rather remarkable that sometimes after amputation of the penis a patient passes into a condition of hypochondriasis, and death results seemingly from this cause alone, without metastasis and without recurrence of the malignant disease *in loco*, or in any of the internal organs. This is a fact which must be considered in advising recourse to this operation, especially in young men. Of course, when a patient has passed three score years and ten it makes very little difference.

The great majority of growths of the penis are carcinomatous in character. Sarcoma of the penis is so rare that it practically does not occur. So far as I know, only two cases of primary sarcoma have been recorded, one by Dr. Porter, and one by Professor Agnew of Philadelphia. Schirrus occurs, but is also rare. Encephaloid is even rarer, and a careful examination of a vast majority of these cases, some of which were formerly regarded as soft cancer, are shown to be squamous epitheliomata. Some authorities have denied that an epithelioma will cause involvement of the internal organs. If the internal organs are affected in some cases they claim that the disease must necessarily be of a schirrus or encephaloid type. Nothing is more unreasonable than this. Metastases occur in epithelioma, not so quickly as in some other forms

of cancer, but they occur, nevertheless. There may be metastases in the liver, spleen, and other internal organs, just as in other forms of carcinoma.

In this connection it may be well to consider the differential diagnosis between epithelioma of the penis and lesions produced by venereal diseases. Chancroid hardly need be considered as in such cases multiple sores are the general rule. If a patient has one chancroidal sore he is likely to have half a dozen, the inoculability of the pus causing a sore wherever it comes in contact with an abraded surface. The life of a chancroid is short, as is also the period of incubation. Between a true chancre and an epithelioma there are important differential points. The age and habits of the patient will assist materially in the diagnosis. An old man would rarely be suspected of having venereal trouble. It must be remembered that epithelioma is rare prior to forty, and that syphilis, *per contra*, is more common under forty. The period of incubation in syphilis is a guide, as is also the history of a suspicious intercourse, and involvement of the inguinal glands occurs early. While the lymphatic glands become involved in carcinoma they do not become affected as early as in syphilis. An epitheliomatous ulcer or wart may exist for six months, a year, or longer, before appreciable involvement of the lymphatic glands occurs. Again, glandular involvement in venereal disease is of short duration. It passes away of itself. Not so with glandular involvement the result of an epithelioma. The condition of the ulcer itself is also important. The ulcer in epithelioma is deeper than it is in syphilis, and the edges are more raised. It is true they are elevated in syphilis, but are more so in epithelioma. In syphilis induration of the tissues around the ulcer is much greater than in epithelioma. In epithelioma induration often exists after caustics have been applied. Accompanying epithelioma there is never an eruption or other constitutional symptoms which will almost surely be observed in syphilis. In any case of doubt, however, and it can be well understood that there will be border-line cases, treatment will clear up the diagnosis. If it is undesirable to wait two or three weeks or perhaps longer for results which will follow specific treatment, a small portion of the suspected ulcer may be put under the microscope for examination and search made for cells which are characteristic of epithelioma on the one hand, and the bacillus of Lustgarten on the other. The latter may or may not be found. Some authorities even deny that it is the cause of syphilis. There can be no mistake about the characteristic cells of epithelioma.

The Brooklyn Memorial Hospital.—In 1891 a few women physicians who had been refused a clinic in the existing hospitals and dispensaries in Brooklyn opened for themselves a dispensary for women and children. The outcome of this movement is the Brooklyn Memorial Hospital for Women and Children, which has thus been founded, developed, and managed by women. The resident staff and the regular visiting staff are all women; some of the members of the consulting board are men. This hospital also maintains a school for nurses.

SPECIAL ARTICLE.

THE MEDICAL NEWS' INVESTIGATION INTO THE CLAIMS OF CHRISTIAN SCIENCE.

BY JOHN B. HUBER, M.D.,
OF NEW YORK;
ASSISTANT TO THE CHAIR OF PRINCIPLES AND PRACTICE OF MEDICINE IN THE NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.

(Continued from page 110.)

CASE IV. — A woman, unmarried, aged thirty-five years. Said to have been cured of double pneumonia by a Christian-Science healer. A sister died from consumption; had been her constant attendant. In November, 1895, she had "double pneumonia"; had been "running down" before that time. Had then been six months in Christian Science. During her illness had eaten little. Slept much. Had pain in her side. Much distress in breathing. Coughed, but could not recall if she coughed up any sputum, or if it was bronze-colored or streaked with blood. Was constipated. Felt hot, "face swollen and purple." (Temperature not taken.) Worked hard against the symptoms, which have passed out of mind. Family thought she was dying. Her nurse "saw at a glance that she had double pneumonia." She would not allow the family physician to see her; no physician made a diagnosis. Her "healer" had to work in this case against adverse thoughts in her house (her sister was a believer in "faith cure," and was inimical to Christian Science). Said she was sick with the pneumonia for three weeks, but was convalescing "some time longer." No medicines were given. [Another person tells me this illness lasted three months.]

CASE V.—A man, about thirty years old. Come into Christian Science two years ago. Before this was a dipsomaniac and an inveterate smoker. During his first treatment his healer said: "This [alcoholism] is a lie; you are a child of God," etc. In describing the scene the subject said to me: "After her treatment I had a violent trembling, and with that came a sense of worship and adoration such as I had never felt before. I felt impelled to fall down and worship her." Since being in "Christian Science" he has not been a drinker nor a smoker. He went through a course of instruction in Christian Science, but did not become "spiritualized" until later. As a child he had scarlet fever, followed by severe earache, resulting in a perforation of the drum. A year ago he had pain in the heart and congestion in the head; feared death. His healer treated him "absently;" after an hour his pain and sensations were relieved. Shortly afterward, while in church, he felt as if half his head had broken loose; there was a great volume of sound. Since then he has had normal hearing in both ears. [I have met this gentleman's healer and am unable to explain his "sense of worship and adoration" upon any rational basis.]

CASE VI. — Wife of subject of Case V., twenty-nine years old. Nine years ago had peritonitis and was very ill for several months, the result of a miscarriage. There was ulceration and congestion of the womb, with constant headache, indigestion, irregular, and painful

menses (every two to three weeks). Was very nervous. She had constipation, flatulence, and prolapse of the bowels. About eight years ago was treated by Dr. A. (R.) At another time Dr. B. (R.) performed an operation for adhesion of the clitoris. Year after year she became gradually worse up to two years ago. She decreased in weight to eighty-five pounds, and her mental condition was "awful—she was almost insane." Two years ago she went into Christian Science. About two weeks after the beginning of this treatment she had a "chemical." Blood and mucus came from the bowels. Then she had intense pain and bloated. Had a chill which lasted half an hour, after which she took to her bed. This was followed by fever; she was "literally burning up." Her healer told her to *take a drug and demonstrate over the drug rather than over her condition.* As her husband read "Science and Health" to her she seemed to get better. Since then has been healthy. Has had "spells" from time to time, but Christian Science has cured them. Now weighs 130 pounds.

Dr. A. writes: "The pelvic organs were involved, there being a salpingitis and ovaritis present. The tubal tumor was a recurring one with remissions in which there was natural outflow through the uterus. The ovaritis was always aggravated by the tubal condition. There was catarrhal inflammation of the colon, especially at the sigmoid folds, and some proctitis, with all the reflex symptoms which usually arise from disease of these organs."

Case VII.—A man, singer by occupation, aged thirty-two years. Was born at eight months. As a small boy he was never sick, but was always weak. Sang in various churches from boyhood. Contracted sore throat easily. At the age of twenty-one years was very delicate. Eight years ago Dr. A. (H.) treated him for grip. Some thought he was going into consumption. All that winter he lived on brandy and milk-punches. About six years ago he studied Christian Science; then he began to improve in every way: his throat was better, and he began to grow stout. About a month after going into Christian Science he had a "chemical" lasting one week, after which he was absolutely well. Formerly he used to be compelled to be excused from church service because of inability to sing; since going into Christian Science he has not missed a service. Five years ago he woke up one Sunday morning with symptoms of grip: aching all over the body, tired feeling, headache, coryza, etc., exactly as during his first attack. He "demonstrated" over this condition, and went to church that morning and sang; he had not been appointed to sing a solo, but the soprano happening to be absent, he sang alone in her place.

[This subject has a treble voice. There is something vague about his eyes, a condition I have observed in a number of these people. He has the "shifting," "wandering," "fugitive" eye. It seems that to "demonstrate" over a condition is to satisfy one's mind that the condition does not exist.]

Case VIII.—Man, aged thirty years; of German birth; a healer, formerly a zither-player by profession. From childhood was considered very delicate. Before he was a year old had an operation performed on his right arm. [Scar here and also on the right ear.] Had "rothe flechen" as a child, which was supposed to be worse than smallpox. Had a European physician as a child; never was expected to be strong or to do any good work, was so puny. Coughed much, and was weak up to about eighth year. Eight years ago had great pain. Said to be rheumatism; others said "inflammation." Had from twenty to thirty tumors, each about the size of a hickory-nut, all over his head. Had great pain, coming on at any time. Had sore throat, which he considered bronchitis. Pain beginning in shoulders and going to other joints; the joints were swollen and reddish, and he had fever. Swelling would not last, but would occur and then disappear. Pain would be so bad that he would scream with the fear that any one in passing might touch his bed. [These conditions were what the Christian Scientist would consider due to "extreme violent self love!"] When he cried red spots would come out on his body. From time to time teeth hurt; would then have to spit a great deal. Pain used to be so great that he had to go about on hands and feet like a dog. Went to a dispensary, and at various times to a number of physicians. Took quinin and other drugs, and afterward his stomach got out of order. He tried Turkish and electric baths. First entered the hot room for thirty minutes. Pain would then leave for sixty minutes, and not one minute longer; after one hour exactly the pain would return. After having tried a number of regular practitioners, he consulted a homeopathic physician, who asked after his mental trouble, and gave him some tablets having the taste of creme-de-menthe. Whenever he was rid of pain he "would be very jolly." When ill he felt that he had suffered because he had left the Catholic Church, the church of his childhood. Then he would become remorseful, and would pray until he would faint. This had no effect on his pain.

Five years ago, at the end of the World's Fair, he went into Christian Science. On he train from Chicago to New York he held the thought that "God is love"; he kept this thought so constantly in mind that in passing Niagara he would not look at the Falls. On reaching this city he went to the Christian-Science rooms. "Everyone came to me because I was such a frail little thing." The wife of the man whose history is detailed in Case XII. took charge of him. She told him "God is life, truth, and love; you may not know now what this thought means, but by and by it will come to you." "Then I went to hear Mrs. X., a Christian Scientist, lecture. She said 'Causation is mind.' I could grasp only this thought out of one-hour's talk. While Mrs. X. was preaching I had hell-fire pain, and wanted to be out in the street. Then just before she stopped speaking I felt rid of pain, and a beautiful feeling came over me. Then my pain stopped, and I have not suffered since." Since then has not used drugs, liquor, nor tobacco. "I love Mrs. Eddy. Oh! how I love her, our mother! If she should tell me to jump off Brooklyn Bridge I would do so instantly, because I would know that if she should

tell me to do so it would be all right." Did not at the time of my visit recall the names of any of his physicians, but he promised to "think them up" and send them to me. Has healed a number of persons with consumption, locomotor ataxia, etc.; promised to send me the names and addresses of some of them, or to take me to call on them; he would make arrangements and would let me know. I have as yet received no communication from him. This gentleman can heal "absently," while lying on his back in his own bed; healed a patient ill seven years whom he had never seen, etc. There is no dispensary record at the hospital mentioned by this subject.

CASE IX.—A woman about forty years of age. Parents living; father's history detailed in Case XI. One of six children, four of whom died between the ages of twenty-three and thirty-four; these four were healthy until they grew up, and then lungs, stomach or bowels seemed to be "consuming away"; all had cough and stomach trouble. One brother had "water on the chest"; a sister attended him, "and the mental pictures taken from him brought on her sickness." Had measles and whooping cough. In childhood she squinted. While asleep had to be watched constantly; breath would come short and she would bound out of bed. Dr. A. (R., now deceased) told mother it was beginning of epilepsy. Had had trouble with eyesight; myopia was discovered at the age of fourteen. Dr. B. (R) said she had malformation of one eye and that she would have to wear glasses for about thirteen years, but she would not, and did not wear them. Had had considerable stomach trouble accompanied by sick headache, vomiting, nausea, diarrhea, etc. Menses came on at twelfth year; amenorrhea occurred frequently. Was married at twenty-three. Horrible nausea before and after marriage. Was well and happy through first pregnancy. Birth of child uneventful. Afterward application to cervix, etc. After birth the old stomach symptoms returned and during two or three days after each menstrual period she retained nothing and vomited blood and mucus. Had never taken opium or bromids. Once Dr. C. (H., now deceased) prescribed an "absinthe drip." She was to take half an hour in consuming it. Took this, and the top of her head was numb; but she had no pain and was able to go about. Took this but once, and would not repeat the dose, feeling that if this intoxicant would relieve her she would have to take it always. About this time she had also kidney and bladder trouble.

About twelve years ago saw a Christian Scientist. After some treatment she forgot all about her eye troubles. The first day her "healer" saw her she assured her this trouble was mental. That night she ate three strawberry-jam tarts, without ill effect. Then she threw away all her drugs. Three days after she ate five tarts without vomiting and slept like a baby; she woke up next morning feeling well. After this for three months she "simply gorged." One day she ate apples, Roquefort cheese and cake, the next morning after which she had headache. Then she was a long time ill and had much distress. Was a year in Christian Science before being thoroughly healed. For eleven years she has had neither physician nor medicines, with the following exceptions: Eight years ago a boy was born. Her "healer" stood beside her bed, but Dr. D. (R.), who was called in, was the accoucheur. He put in some stitches, which he removed about a week later. He made three visits during her confinement. Twenty minutes after the birth she was sitting up and eating a hearty dinner. In three days she was up and walking about her rooms. One week later she went to a dinner-party in full evening dress. Did not want to nurse this baby and the breast was bound up without applications. Three days later her breasts were hard, like stones. She had a thorough movement of the bowels, and then her milk flowed like water. Three weeks after this birth she sang at a concert. Since this birth her menses have been regular. Dr. D. corroborates statements made concerning his own work in this case.

[This subject is a "healer." "I have had gifts as a nurse and have therefore been able to ascertain signs of disease." Treated the subjects of Cases X and XI; among others she "cured" a case of tumor of the cheek which was almost the size of a walnut. After about three-weeks' treatment the tumor was the size of the head of a pin. Does not now know whereabouts of this man or how he can be reached.]

CASE X.—A man, about fifty years old. Said to have been cured of diphtheria by the subject of Case IX.

This man is supposed to have had at the time of his "healing," tonsillitis, quinzy, and malignant diphtheria. He had been for two weeks under the care of Dr. A. (H.), now deceased. It is alleged that on the last day of the doctor's attendance he looked into the patient's throat and saw a membrane on the tonsils and pharynx. The "healer" did not make an examination of the parts and therefore did not see any membrane. There is no record of a bacteriologic examination. Patient had fever [temperature not taken by "healer"]; could only whisper. Within an hour after the doctor's last visit the "healer" took up the treatment; this was at 5 P. M. In three hours patient took ice and raw oysters; within twelve hours he ate a hearty meal and was well. [This "healer" did not ascertain symptoms; she simply had been told the patient had diphtheria. "If the name of the disease is known to the healer it succumbs more quickly to his efforts; but a very spiritual "healer" can heal just as rapidly if the name of the disease is unknown to him."]

CASE XI.—A man, aged seventy-six years. Father of subject of Case IX., by whom, with the added efforts of another "healer," he is said to have been cured. His illness began in 1855, when something fell on his big toe. Inflammatory rheumatism resulted; there was pain with red and inflamed joints. The inflammation traveled from the injured toe to other joints. This pain seemed always worse about two o'clock in the morning. He suffered from rheumatism and gout from 1855 up to 1891 with more or less intensity. There were "calcareous" deposits about the knee-joints, so that the enlargements were noticable through the trousers. At various periods he was confined to his house for six months at a time. About 1880 he left the city. His mind was then off him-

self. When he went away he got better. Felt better when traveling about. On his travels forgot his gout and was happy. At one time he went to the Hot Springs; for the first five weeks there he felt good; after that he felt as bad as ever. He had tried electricity, springs, baths, etc. He took a number of drugs, among them McMunn's elixir of opium; from 1885 to 1891 he took enormous quantities of Blair's pills. During these years he had many physicians; he could not refer me to any of these, not being able to recall their names. Two physicians, Drs. A. and B. (both R.) treated him at one time for kidney trouble, but they did not see or examine his "calcareous" deposits.

In January, 1892, he took up Christian Science; at first he was not improved; he attributes this to the fact that he had no faith in Christian Science at that time. Latterly he did believe in it after which his improvement was rapid and he soon became well his "calcareous" deposits disappearing. Soon after taking the treatment he had a "chemicalization" and became worse. Then he became progressively better. At first his daughter treated him, without much success; then she called in another "healer" to help her, after which he became well.

Dr. A. and B. are associated, Dr. A. being the senior. Dr. A. does not recall this subject. A history of the man is published in a Christian-Science tract as a "remarkable experience of one cured through Christian Science." Among a number of statements printed in this tract is this: "I had up to that time employed the most eminent physicians." Concerning the names of these, or any one of these physicians, except as mentioned above, his memory is now hopelessly defective.

CASE XII.—A lawyer, aged about fifty years. From youth up had a cold in the head and most intense pain all the time. Never could put hand to anything cold like marble, otherwise cold in the head would result. Finally it got so bad he "*nearly* put a revolver to his head for the purpose of shooting the top of his head off." Went South seven years because of this catarrh. This was twenty years ago; in the warmer climate his catarrh was better. Ten years ago went into Christian Science before which he had been treated by various physicians; gave the name of one who is now dead; would not give the names of any others. In Christian Science he was entirely healed of his catarrh in a week. It would occasionally return, and then he would "demonstrate" over it. Believes that catarrh is caused by different qualities of thought in different people. Treat the cause (using the term as referred to in Christian Science). What was the cause? In this case the original cause was sin. Has been well while in Christian Science.

This gentleman's wife is also a Christian Scientist. They are both "healers." "All Christian Scientists are healers." It was this lady who treated "absently" the deaf young woman with irregular menses before mentioned. When this lady was pregnant, her husband, the subject of this history, had the morning sickness, the vomiting and other symptoms due to pregnancy, of which symptoms the lady was free. This was the case while two children were in the womb, previous to their coming into Christian Science. Since they have been in Christian Science no children have been born to them; therefore it is impossible to judge if in Christian Science the husband would again have been in the condition recorded. There was a bond of sympathy between husband and wife, so that when one was ill the other was easily affected and distressed; such is not now the case.

CASE XIII.—A woman aged about fifty years. This subject preferred to write her "testimony," which is given verbatim:

"It is four years since I came into Christian Science; up to that time I had been a sufferer some twenty-eight years. I had had the advice of many of the best physicians. I had been in the ——— Hospital and one of the best sanatoriums of New York City, all without receiving the desired effect, my trouble being surgical. I was much discouraged. I was benefited but far from well; prostrated at one time for nine months, at another time five months, a perfect slave to nervine, my nervous system being down to the last degree. What I suffered tongue could not tell; in 1894 I was taken down to my bed; again my doctor thought it necessary to call a specialist. After consultation I learned that they differed in opinion; one thought if certain things were done at my time of life I would certainly pass out. The other thought if they were not done I would pass out.

"While in this confusion of mortal mind a Christian Scientist called to tell me what 'Science' had done for her; I told her to send me the book called "Science and Health, with Key to the Scriptures"; she did so. I began to read it; it so lifted me above all thought of doctors and material things that I said 'surely this is good, I will try it; if I do not succeed the sanatorium and doctors will be here just the same.' I then went to a Christian Scientist for treatment. In all this time I have taken no medicine; have been able to overcome all obstacles arising before me, my longest walk being one block; to-day I can walk twenty without fear, in fact I walk all day long around my home, performing my household duties. Please accept this as an expression of gratitude to Christian-Science healing, with the hope that others may receive a similar blessing."

Dr. A. (E.) her former family physician, and Dr. B. (R.) were referred to. Dr. A. states that he had been the family physician for many years. In his opinion the subject never had any really serious sickness. At one time she had a slight prolapse of the womb, for which a cup pessary had been prescribed. She feared her womb would protrude from the vulva. She was, as were all the family, of a very nervous temperament, and to this Dr. A. attributed most of her ills, which were, in his opinion, largely imaginary. Dr. B. states that the subject had complete laceration of the perineum, extending through he sphincter. This he closed and the operation was completely successful (she stated to me that Dr. B. had very decidedly helped her). Dr. B. considers her to have been afflicted with hysteria in a most intense form.

CASE XIV.—Actress, about twenty-eight years old.

Had all through life been troubled with headache, pain in the eyes, difficulty in reading, and dyspepsia, which was aggravated by the conditions of her professional life. She had a "tendency to consumption of the stomach." Was nervous and sleepless at night. At one time had rheumatism. Had had her eyes examined; astigmatism had been found and glasses had been prescribed. Had uterine trouble, for which she consulted Dr. A. (H.) and others; for this electricity had been applied. Since February, 1897, has been in Christian Science; ever since she has not used glasses and has been well.

[Dr. A. does not recall this case. An arrangement of the hair, *a la* Cleo de Merode, partially hides a slight strabismus, which Christian Science has not yet rectified.]

Case XV.—Actor, aged about thirty-five years, husband of the preceding. Went into Christian Science in February, 1897, before which he had dyspepsia which now never troubles him. Shortly after going into Christian Science he had a "chemicalization," during which he was in a very bad state indeed; he had "a very hard time of it." Has observed the following phenomenon: Before going into Christian Science he would of an afternoon drink a great deal of whisky, and he found that if he would take acid phosphate after drinking he would not feel any ill effects from the alcohol. One afternoon after becoming a Christian Scientist he, as before, took a great deal of whisky. Then he concluded to try an experiment; he would take acid phosphate, but with a distinct intention of taking it *as a drug;* this he did and became, in consequence, very ill indeed. This result he attributes to the fact that he took the phosphate as medicine.

Case XVI.—Artist, aged thirty-seven years. Had diphtheria and scarlet fever in youth. Had dyspepsia. Suffered from supra-orbital headache, nausea, and vomiting. Eleven years ago eyes were examined by Dr. A. (H.). Had formerly been easily fatigued. Ten years ago went into Christian Science, at which time he discontinued the use of glasses. Suffered four years with headache, nausea, etc., but was determined not to wear glasses. During these four years he went to different "healers," who did not help him. Finally he found one who healed him. During the last six years he has never been ill, and during the last ten years he has not worn glasses. His eyes do not hurt him, although he uses them constantly for painting, etc.

Dr. A. writes: "He first consulted me September 2, 1885, complaining of trouble with his eyes at both near and distant vision, seeing double at times. What so-called reflex symptoms he complained of I cannot now say, but I have no doubt they were many. There was evidently spasm of accommodation present. I used atropin and on examination under its influence found the following correction:

R. + 1.25 D sp. c. — 1. D cy. axis 15° = $\frac{5}{5}$.
L. + 1.50 D cy. axis 75° = $\frac{5}{5}$.

September 3, 1885, ordered:

R + 0.25 D sp. c. — 1.25 D cy. axis 15° $\frac{5}{5}$.
L. — 0.50 D sp. c. + 1 D cy. axis 75° $\frac{5}{5}$.

"This was as near as I could get him to accept the correction as found under the drops. At the time he said that this correction was perfectly satisfactory, though I assured him it was not to me, as it showed too much evidence of spasm, but under the circumstances I would order it and he must keep himself under observation. This he did not do. I next saw him professionally on September 7, 1889, and he reported his eyes as bad as ever. I then made an examination and found he accepted:

R. — 1.50 D cy. axis 180° = $\frac{5}{5}$.
L. + 0.50 D sp. — 1.75 D cy. axis 5 = $\frac{5}{5}$.

"As this did not compare with any of the previous tests I asked permission to use homatropin; this was refused and whether I ordered the glasses found acceptable in the last test or not I cannot say, but think not. My professional connection with Mr. X. has been but limited and that most unsatisfactory as I was never able to follow up the case as I desired.

"Mr. X. always struck me as being a person of a highly sensitive, nervous organization with very keen perceptive faculties, easily influenced by his present surroundings whatever they might be. I am not surprised that he has become a convert to Christian Science as his temperament would seem to be just such a one as would naturally drift into any new cult or fad, and the more easily so in his case from the fact that his sister in this city is a recognized high priestess, as it were, in that sect here."

The doctor knows the subject well outside of professional relations. Refused to have his eyes retested. Has odd mannerisms. Has a colorless, grayish-hued complexion, a flabby and moist hand and a feminine voice.

Case XVII.—Civil engineer, about thirty years old. Father had dandruff; became bald at the age of thirty-five. Had dandruff, "eczema" of scalp, ears, and on chest. Was losing hair rapidly. Feared baldness. Used to saturate his hair with lotions, salves, etc. Two years ago went into Christian Science. Gave up the use of lotions and ointments. Has not made any topical applications since. Simply brushes his hair. Treated five times by a "healer," going every other day. For two years has not had dandruff, loss of hair or "eczema." Has now a good head of hair.

[A contribution to the question of the inadvisability of using topical applications in threatened alopecia.]

(To be Continued.)

THERAPEUTIC NOTES.

Dry Treatment of Suppurative Otitis Media.—Goldstein (*Laryngoscope*, December, 1898) says that in most cases of suppurative inflammation of the middle ear, the dry treatment gives better results than treatment by irrigations and wet dressings. A tuft of cotton on a probe will absorb the secretion and cleanse the canal more effectually than a stream of fluid. When the membrane is perforated, as is usually the case, there is also the dan-

ger that a stream will convey the infection to a still healthy part, for instance, the mastoid cells. If the ear is treated dry, the formation of granulation tissue is also reduced to a minimum. If the opening in the membrane is very small, a Eustachian catheter may be used with a Globe nebulizer, containing a mixture of iodid, 3 grains; carbolic acid, 4 grains; and benzoinol, 1 ounce. By steady inflation the remaining secretion may be forced out through the drum membrane, and at the same time an application of antiseptic substances is made to the mucous lining of the middle ear. A concentrated solution of peroxid of hydrogen is of advantage in seeking out pockets inaccessible to the syringe and the cotton-mop. A medicine-dropper is used for its introduction, and by shifting the head of the patient, the peroxid can be made to come into contact with any portion of the middle ear which it is desired to reach. Emphasis is placed upon the necessity of keeping the nasopharynx in a clean and aseptic state in the treatment of suppurative otitis media.

Treatment of Baldness by Simple Aseptic Irritation.—JACQUET (*La Presse Med.*, December 10, 1898) says that while all dermatologists agree that cutaneous irritation is the first principle in the treatment of baldness, there is no agreement as to the amount of irritation which will give the best result. Permanent irritation is certainly not as good as a slight irritation which can be renewed at will. By this manner one gets the advantage of the vascular dilatation, the hyperthermia, which favors the papillary vitality, and avoids the ultimate slowing of the blood stream, and the leucocytic migration and interstitial exudation which takes place if the irritation is continued to the point of inflammation. Transitory hyperemia can best be caused by repeated slapping of the scalp with a sharp brush, made of good pig's bristles. The brush should be applied all over the bald area, and along the margins of the hair. In a few seconds the scalp will become red and pulsating, a condition which will last for half an hour or more. The treatment should be repeated morning and night. In his own case Jacquet caused the hair to grow again on a bald spot in his beard as large a two-franc piece, by making applications of the brush in the manner described, twice a day for four months. In other cases he has made more frequent applications, five or six a day, and has attained more rapid results. To keep the brush in an aseptic condition, he plunges it each time before it is used, into the following solution:

Alcohol		℥ iv
Ol. ricini		℥ i
Hydrarg. chlor. corros.		gr. ij
Ext. opoponacis, Tinct. cocci cact.	aa	gtt. xxx.

The brush is shaken as dry as possible before it is applied. If a brush is used which is made of wires with a rubber back, it will be very easy to keep it aseptic by this solution.

Fetid Breath and Its Treatment by Carbonate of Creasote.—BAYER (*Rev. de Therap.*, December 15, 1898) believes that chronic affections of the nasopharynx are the cause of fetid breath in obstinate cases. For instance, in women who are annoyed by bad breath at the period of menstruation one can always make out at such times a congestion of the nasopharynx with an increase of its secretion. The best treatment is the intratracheal injection of carbonate of creasote. It is better to use the carbonate than the pure creasote as the latter sometimes provokes spasms of suffocation, whereas the carbonate of creasote, slightly warmed, may be injected by the ordinary intralaryngeal syringe without unpleasant effects, in quantities of .5 to 1.5 c.c. (15 to 45 drops). Such an injection does not produce irritation, and the relief is often so marked that there is no occasion to repeat it.

Treatment of Varicocele by Subcutaneous Ligature.—NIMIER (*Rev. de Chir.*, October, 1898) suggests the following simple method of treating a varicocele: The patient lies upon his back and the testicles are held well up against the pubic bone by an assistant, the redundant scrotum being spread out like an apron before the thighs. A Reverdian needle is thrust into the scrotum from the left side, and passes across its whole breadth, just beneath the skin anteriorly until it emerges at the right side. It is threaded with silk and withdrawn. It is then introduced into the same puncture on the left side, and passes along the posterier wall until it emerges through the puncture at the right side. Here the other end of the silk thread is passed through its eye and the needle is again withdrawn. The silk thread then surrounds the whole scrotum subcutaneously. It is drawn tight and tied, the knot being pushed through the opening in the skin. A little cotton and a suspensory bandage constitute the dressing. The reaction is slight, but it is better for the patient to remain in bed for one week. The writer insists upon the importance of strict asepsis.

Rebellious Constipation Cured by Massage of the Gall-Bladder.—BERNE (*Jour. des Practiciens*, No. 47, 1898) has found that in certain patients massage of the gall-bladder gives almost as good results in overcoming constipation as massage of the whole abdomen. In some patients massage of the whole abdomen is contraindicated, as in the presence of an abdominal tumor, or an excess of adipose tissue, or a particularly sensitive skin, as well as in young women in whom the close association of the pelvic and abdominal organs, make general abdominal massage undesirable. Moreover, constipation is often due to sluggishness of the biliary flow, and massage over the gall-bladder corrects this. The operator sits at the right side of his patient, and makes deep, gentle plunges with his fingers from below the false ribs upward toward the under surface of the liver. Ten minutes of this exercise, three hours after the midday meal, and repeated daily for ten or twelve days, will suffice to bring about a normal passage without the help of drugs. From thirty to forty days are required to effect a permanent cure. The passage of bile into the intestine is shown by the restoration of the normal color of the stools, and the disappearance of their fetid odor, while the body of the patient regains its natural embonpoint.

CANNED BEEF FOR THE ARMY.

There has been a great deal of space devoted during the past week in the daily papers to the question of bad canned beef supplied the troops during the recent campaign. A tendency is manifest to confuse two aspects of the question that it is very necessary should be kept thoroughly distinct. Most modern scientific authorities are agreed that it is possible to preserve meat by canning, and yet retain practically all its nutritive value; at least, there are enough good authorities of this opinion to perfectly justify the Army Medical Department in its endorsement of the orders of the commissary department for such supplies for the soldiers whenever the better and more satisfactory fresh meat could not be obtained. The household consumption of immense quantities of American canned meats in this country and in Europe during the last ten years testifies to the value and palatableness of the article when it is properly prepared and preserved.

Here comes in, however, the second aspect of the question of the bad canned beef supplied the army, the aspect of the question that the testimony of officers and men shows sadly to need investigation. The evidence goes to show that many of the cans became swollen during transportation, evidently from the pressure of gases of decomposition; further, that the meat was even in other cans found tainted (to put it mildly) when opened; and, finally, that many of the cans were improperly filled, fat, gristle, and a tallow-like substance forming the larger part of the contents. These facts go to show, not that canned beef as such is bad, but that the articles supplied the Government for the troops were badly packed, imperfectly preserved, certain necessary precautions for their preservation being neglected, and that the quality of the product was allowed to deteriorate from its usual standard in the hurry of executing a large contract for the Government. There was somewhere either a lack of proper inspection and a condemnable failure to test the product before its acceptance, or there was deliberate fraud by the delivery of an article inferior to that contracted for, or collusion in its acceptance.

The question thus put calls for the most searching investigation and no trouble or expense should be spared to properly place the responsibility. What is to be investigated is not whether canned beef as ordinarily put up is a proper food or not; that question was decided long ago scientifically and practically. Certain phases of the present agitation by failing to bring out this fact are liable to do a great deal of harm to a great and very valuable American industry, while at the same time helping to divert attention from the criminal neglect or deliberate fraud that led to the furnishing of this particular lot of ill-preserved, unsuitable canned material to the army. As this heedless or fraudulent connivance was the source of a great deal of suffering and an undoubted cause of no little sickness among the troops, it deserves the most thorough investigation. No pains should be spared to brand publicly and indelibly the parties who, for what is evidently sordid reasons, seriously endangered the health of the troops; nothing should be left undone to mete out to them the punishment they so richly deserve.

INHUMANITY AT THE VIENNA GENERAL HOSPITAL.

The Philadelphia daily papers and some of their New York contemporaries contain lengthy comments and discussions as to the way in which patients are treated in the General Hospital at Vienna. The

discussion was aroused by some remarks made on the subject at the sessions of the Pennsylvania Anti-vivisection Society which was holding its annual meeting in Philadelphia. A prominent member of the society stated that the hospital was really a clinical laboratory in which often unjustifiable experiments were carried out on the poor, defenceless patients. She even stated that she had been informed by a young American physician who had studied in Vienna, that if a case was particularly interesting or especially inexplicable, the patient was *retained* in the hospital until the termination of the case in order to secure an autopsy, the insinuation being that not overmuch medical care was exerted to delay the termination of the case or put off too long the post-mortem examination which might prove of precious value to scientific medicine.

A saving sense of humor is a most precious thing in life. It is evidently sadly lacking in certain at least of our antivivsectionist friends if they took this last story seriously. It is a well-worn joke among American students at Vienna who delight in relating it to humorless Austrian friends and to gullible newly arrived Americans with the purpose of observing the horror produced by the canard. We have heard it told in America, but seldom saw it fail of its real purpose —that of a joke by exaggeration so dear to the American heart. It is typical of the antivivisectionists that they should be taken in by it, for the whole of the antivivisection movement is characterized by a failure to see things in their proper proportions; by an endowment of animals with a sensitiveness to pain that belong only to neurotic hyperesthetic individuals of a genus much higher in the scale of evolution; by a failure to realize scientific advances because they happen to have been made by methods that are opposed to their eminently narrow views.

The American medical-students' joke is perhaps not in the best of taste, but when people are so ready to be taken in what genuine American could resist the temptation "to take a rise out of them"? Meantime the good name of the great hospital at Vienna, the source of so much that is best in modern scientific pathology and diagnosis is involved and the humanity of her great professors and investigators is questioned. We think that most Americans on their first arrival in Vienna are surprised and somewhat shocked by the treatment of patients at the hospitals, but so are they shocked when they come to realize the general treatment accorded the lower classes in all the circumstances of life in which they come in contact with those above them in social status. It is this condition of things and not any over ardent zeal for clinical experimentation that leads to the treatment of patients, that an American is at first apt to resent. The proof of this lies in that fact that while considerably less than one-half of the General Hospital is given up to clinics that are used for teaching purposes, there is no special desire on the part of patients as a rule, to get into the non-teaching departments where there is practically no clinical experimentation. Personally we know of patients who had been transferred at their own request from the non-teaching department to the wards of clinical professors at the university because they thought they would receive better medical care.

Much of this complaint about the treatment of patients at Vienna is founded on inexperience of national differences of feeling in personal relations. It is the expression of that false feeling that other people must do as we do or they are indefensibly wrong, and finally it is a putting into other people, as the antivivisectionists do with animals, of certain finer feelings of sensitiveness that they are not possessed of at all. The great teachers of medicine at Vienna for the last half century, who have accomplished so much for the good of humanity by their investigations, do not deserve the aspersion thus cast upon them without a proper knowledge of the facts. The present heads of the great medical and surgical clinics at Vienna are personally some of the kindliest men in the medical profession. Their names and characters are ample justification that there has been and will be no abuse at Vienna of the sacred privileges that bind physician to patient in all ranks of life all over the world.

PHAGOCYTES IN A NEW ROLE.

METCHNIKOFF'S theory of phagocytosis has always been a very captivating one This question of certain cells possessed of a sort of automatism, going out of their own volition, as it were, to meet the enemies of their host, and, if necessary, to lay down their lives in his defense, has something in it that

wonderfully attracts human interest. At times the importance of the theory has seemed to be waning, but to those who are in touch with Metchnikoff's work and that of the brilliant school of young experimental pathologists he has gathered around him at the Pasteur Institute, the question has always seemed a vital one. It is only necessary to have heard Metchnikoff himself upon the subject or to have followed the ingenious experiments that have been employed during recent years in showing the fallaciousness of certain objections to the theory, to realize that phagocytosis is and will remain an important issue in the pathology of inflammation so long as our studies of that subject are carried on from the present standpoint.

Some recent, brilliant, experimental work seems to show the phagocytes in a new rôle, and one that brings them much closer in touch with practical medicine, because it shows them as aids in medicinal therapeutics. Some time ago Kobert, at Dorpat, showed that when the salts of silver and iron are used internally, besides passing through the intestinal mucosa into the blood- and lymph-streams by diffusion, a certain amount of these substances is taken up by leucocytes in the walls of the intestines and carried here and there through the system. Metchnikoff has now been able to confirm these observations, especially as regards the absorption and distribution through the system of the salts of mercury. He has been able to demonstrate the presence of portions of the mercuric salts employed in the observations in leucocytes obtained from peripheral parts of the organism. This function of carrying the salts of the metals is demonstrable especially for the polynuclear and mononuclear leucocytes, cells of mesodermic origin, which are just the ones that englobe and destroy microbes.

The importance of this discovery can scarcely be be overestimated. The salts of the metals are among the most efficient therapeutic drugs we have. Their action and mode of absorption have always been rather mysterious. Iron, though generally acknowledged to be a very useful drug, has had a most checkered therapeutic career, because of uncertainty as to the mode of its absorption and the manner in which it acts. This new discovery opens up a vista of possible revolution of our knowledge of drug absorption. It introduces a biologic factor where only chemical and physical forces were previously thought to be at work. It cannot fail to be pregnant with suggestion for workers in the two sciences of therapeutics and physiology.

GASTRO-ENTERIC DISEASE IN WOMEN.

The great majority of women in the artificial environment of civilized life receive a considerable amount of treatment at the hands of the gynecologist. Diseases of women comprise a specialty as firmly established in the minds of the laity as in the estimation of the medical profession. Thus, the natural tendency is to concentrate the attention upon the genital organs and to regard as of secondary importance any symptoms pointing to other organs, unless occurring under circumstances that obviously free the pelvic viscera from all responsibility.

The time is not remote since morning sickness and hyperemesis gravidarum were associated absolutely with uterine changes. There was no thought of careful examination as to the state of the stomach, none of rational therapeutics of the gastric disorder. If not too troublesome, it was passed over as a mere physiologic occurrence. If it became more serious, one remedy after another was used empirically—or rather in spite of empiric probability of its uselessness—without the least idea that the pregnant woman could have a gastric catarrh or a functional disturbance of digestion which required diagnosis *per se*. If the symptoms became extreme and nutrition failed, there was still no thought of examining and of treating the stomach—unless the indiscriminate administration of drugs be dignified with the name—but counsel was called to consider the advisability of interrupting pregnancy.

Similarly, in the case of gynecologic patients, emaciation, constipation, or diarrhea, loss of appetite, nausea, vomiting, pyrosis, intestinal flatulence, etc., were often mentioned but, apparently, without conceiving that they might mark the essential or a coexisting but independent trouble.

Within the last few years writers from the standpoint of internal medicine, or from that of the newer digestive specialty, have raised their voice against the old saw that "The womb is the woman"; they have pleaded for a careful examination of the state of digestion before relegating all kinds and degrees

of digestive failure to the symptomatology of a pregnant uterus, a linear cicatrix of the cervix, a slight exaggeration of the normal secretion of the vagina, or virginal anteflexion of the uterus. More recently still, a protest has been raised against the practice of performing an exploratory celiotomy without first having exhausted the diagnostic powers of the clinician.

In a recent volume of *Archives Générales de Médecine*, Dr. Paul Delbet reports an extremely interesting case of a woman aged twenty-three, who had borne two children and who had, subsequently to the second delivery, developed a series of gastric symptoms marked especially by vomiting and emaciation. Practically, the only gynecologic symptom was a moderate leucorrhea, but the uterus could be felt diverted to the right and there was a mass as large as two fists in the left side of the pelvis. The only other examination made was an external investigation of the abdomen which resulted negatively. After several months' local treatment, first by another physician then by Delbet himself, an operation was proposed and agreed to. On opening the abdomen, the stomach was found prolapsed and dilated, reaching nearly to Poupart's ligament and the pubes, and held in this position by adhesions of the great omentum, which latter constituted the pelvic mass. After loosening the adhesions and tying off the rolled up omentum, the stomach rose a few centimeters and, ultimately, regained its normal position and size.

There is only one particular in which we could criticise Delbet—not to mention the error of diagnosis and early therapy which he himself frankly admits. Certainly, no one could be expected to distinguish by vaginal touch an omentum from one of the tumors which might reasonably be expected in the pelvis. It is only reasonable to expect, however, that the routine external examination of the abdomen should have revealed so enormously dilated and extensively displaced a stomach. Succussion, percussion, auscultation, even without the introduction of air through the tube, or water by the normal process of swallowing, auscultatory percussion, perhaps, mere palpation and inspection—any one of these methods might, and any two or three of them should be sufficient to locate the stomach, unless in a patient with enormously thick abdominal walls, which was not the case in this instance. By the aid of combined manipulation, using the tube, the solid sound, the endogastric electric light or some acoustic contrivance within the stomach, the diagnosis could have been still further aided.

"But," says some abdominal surgeon, "what would have been the use of making a diagnosis? The stomach could not have been freed from its adhesions nor the omentum and the diseased ovary removed without opening the abdomen." We are not setting up a man of straw to carry on an imaginary sophistry, for just this argument has been used by many surgeons, in behalf of the liberal use of exploratory incision. Our reply is this: except the elimination of gross errors as regards asepsis, no one factor has so greatly diminished the mortality from celiotomy as rapidity in operating and the avoidance of exposure and handling of serous structures. It is all wrong to wait till the abdomen is opened before making a serious attempt at an accurate diagnosis. There must remain cases in which, in spite of every care, the abdominal incision will reveal some surprise; there will be cases in which the indication for immediate operation will prevent an elaborate study of the conditions present. But, in the average abdominal case, there is the same need of the service of a skilled diagnostician as of a skilled surgeon. Rarely, the same man may combine these qualifications, usually life is too short and the medical art too complicated for any one human intellect to excel in more than one particular. Often, under the best circumstances, the surgeon will be called upon to revise a diagnosis in the face of organs exposed to naked-eye inspection, and to adapt his maneuvers according as complications arise. But this, by no means, relieves him of the responsibility of having studied the case in advance and of forming carefully and thoroughly well-matured plans of interference.

ECHOES AND NEWS.

A Chinese Physician in Indiana.—A Chinese physician recently applied for registration in Indiana, presenting a Chinese diploma.

Twenty-six Thousand Patients, All Tailors.—One of the lodges in Berlin, that of the tailors, has 26,000 members, and its own exclusive doctors. What an opportunity to study occupation neuroses!

Officers of the New York Medical League.—At the recent annual meeting of this organization Drs. J. E. Janvrin, J. C. Schminke, and J. J. Noll were reelected president, secretary, and treasurer respectively.

The New York County Medical Association.—At the annual meeting held on January 16th, at Mott Memorial Hall, Dr. Frederick Holme Wiggin was elected president, Dr. Parker Syms first vice-president, and Edwin Gaillard Mason second vice-president.

The American Neurological Association.—The next meeting of this Association will be held at Atlantic City, N. J., June 14, 15, and 16, 1899. Dr. J. Hendrie Lloyd of Philadelphia is president, and Dr. G. M. Hammond of New York, secretary and treasurer.

The American Orthopedic Association.—The thirteenth annual meeting of this Association will be held at the New York Academy of Medicine, May 31 and June 1 and 2, 1899. Dr. W. R. Townsend of New York is president, and Dr. John Ridlon of Chicago, secretary.

Students in Berlin University.—The attendance at the Berlin University is greater this winter than ever before in its history. There are at present 6151 matriculates as against 5606 last winter, and 4648 in the last summer semester. The medical department has its fair share of these, 1311 being registered under its faculty.

Hospitals for Consumptives in New York State.—On January 25th a bill was introduced in the Assembly at Albany which will allow cities of the first class to establish, equip, and maintain outside of their corporate limits, and with the approval of the State Board of Health, hospitals for the regular treatment of consumptives.

Four Suicides in One Family.—Seven years ago Mrs. I. L. Corwin of Newburgh, N. Y., was found dead in her bath-room, having cut her throat. A year after, her husband committed suicide by shooting himself in the head; a year after this their oldest son hanged himself, and on January 15th their daughter, Mrs. A. M. Weed, died from taking a poisonous drug, supposed to be carbolic acid.

Anti-Tuberculosis Bill.—A bill has been introduced in the Senate at Albany requiring all cattle brought into the State to have had a test thirty days previous at the hands of a State official who is empowered to furnish a written permit to import them. All transportation companies are forbidden to carry cattle without such certificate and permit. Violation of the law is punishable by fines.

Smallpox at Norfolk, Va.—The smallpox situation at Norfolk has improved greatly. The compulsory vaccination order is being rigidly enforced, the city has been thoroughly cleansed and the disease is well under control. Nearly 75.000 people have been vaccinated. By order of Surgeon-General Wyman officers of the Marine Hospital Service have been examining every passenger leaving the city.

Professor Edgar Delivers an Address in Philadelphia.—Upon the invitation of Professor Hirst, Dr. J. Clifton Edgar, Professor of Obstetrics in the Medical School of Cornell University, delivered an address before the students of the University of Pennsylvania, on the evening of January 19th. This was the first of a series of annual lectures, to be delivered under the auspices of the Barton-Cooke-Hirst Obstetrical Society by eminent obstetricians of other colleges.

A New Medical Journal.—With the beginning of the year 1899 there has been an extraordinary number of new medical journals launched upon the crowded and uncertain sea of medical literature. The latest is *Obstetrics*, edited by Dr. Edward A. Ayres, Professor of Obstetrics in the New York Polyclinic Medical School and Hospital, and published by the Van Publishing Company, New York. *Obstetrics* is a companion journal to *Pediatrics*, published by the same company, and appearing monthly. A pronounced feature is a complete review of current obstetric literature.

Made an M.D. by Mail.—Frank K. Irving of Passaic, N. J., was on January 18th tried in the Court of Quarter Sessions at Paterson for practising medicine unlawfully and was convicted. He had failed to file for registration in the office of the county clerk a certificate from the State Board of Medical Examiners. In his defense Irving said that he was a graduate of the National Electro-Therapeutical College of Lima, Ohio. He admitted that he had not attended any college of medicine but had studied medicine by means of the correspondence method for a period of four months. He was then examined by mail, after which he was graduated.

Incompetent Surgical Service.—A judicial decision recently given in Indiana states clearly the obligations of a railroad company which undertakes to provide hospital treatment for its employees who are injured while in its service. The Wabash Railway retains a part of the salaries of its employees for the maintenance of a hospital and the fees of surgeons employed to treat these employees. The plaintiff, a fireman, had his foot crushed while at work. The surgeon amputated. It was proved that the surgeon employed by the company was drunk while attending the plaintiff, and that the amputation was not necessary. A verdict was, therefore, given for the plaintiff to the amount of $6500.

Christian Science.—An address upon "Christian Science, a Sociological Study," delivered by Dr. Charles A. L. Reed, before the Northwestern Ohio Medical Association at Lima, Ohio, December 8, 1898, has been published in book form at the request of the Association. The object of publication is to place the address in such form that it may be available at small expense to physicians, clergymen, educators, and others for distribution in their respective communities. It is an argumentative discussion of the subject, and to a certain degree supplements the information presented in the MEDICAL NEWS' investigation of this cult now being published in our current issues.

An American Bon Mot in Vienna.—One of Pean's followers, a young surgeon in Paris, performed laparotomy

upon a woman. She did not recover promptly, and a second laparotomy was proposed, but to this the patient would not consent. Later she went to a hospital, and was operated upon by Marchand five months after the first operation. To his astonishment, he removed from the peritoneal cavity a metal Hegar's dilator, which had been left in the abdomen by the first operator. In commenting upon this case a Vienna editor says: "Now we see the force of the advice given by an American surgeon who recommended in order to be sure that nothing was left in the abdomen, the counting not only of the sponges and instruments, but of the assistants as well."

Obituary.—Dr. Charles Fayette Taylor died at Los Angeles, Cal., on January 25th, from pneumonia complicating grip. He had been an invalid fifteen years. Dr. Taylor was born in Williston, Vt., April 25, 1827. He was graduated from the University of Vermont in 1856, and soon after located in New York City, devoting himself mainly to deformities. It is chiefly due to his untiring energy and faithful services that the New York Orthopedic Dispensary and Hospital was established. He was eminent as an orthopedic surgeon, and invented a number of valuable surgical appliances. He wrote a number of treatises on his specialty. He was a Fellow of the New York Academy of Medicine, a member of the American Orthopedic Association, the New York County Medical Society, and a corresponding member of the Imperial Vienna Medical Society.

Deaths under Unusual Circumstances.—On January 25th two physicians called upon Mrs. Kate Witmann, in Weehawken, N. J., having been engaged to perform an operation upon her. While preparations were making, Mrs. Witmann retired; when the physicians entered her room a few minutes later they found her dead.—Frank Pinz, a resident of New York City, had been a sufferer from rheumatism for four months; during this time the pain had been very great. On January 26th the shop in which Pinz was employed being warm, a fellow workman opened a window in front of his bench. Pinz jumped out and was instantly killed.—Mr. and Mrs. Reuter, of Brooklyn, died on January 26th, within three-quarters of an hour of each other, the physicians said, of apoplexy. Mrs. Reuter died first; just before dying, Mr. Reuter said "My wife is dead; my heart is broken."

Magnetic Healers in France.—The position of magnetic healers in France will soon be definitely decided by the Court of Cassation, an appeal having been made to the Criminal Chamber of that court, from the Court of Angers. In 1894 the latter court decided that a magnetic healer, as long as he confined himself to the practice of the healing art in accordance with his own ideas, was not breaking the law, which says that no one shall practice medicine except a duly licensed graduate of medicine. In 1893 the tribunal of the Seine took a broader view of the law, and found guilty of its infringement a magnetic healer who was practising medicine in his own way on the ground that the practice of medicine was intended by the act to mean not only the administration of drugs, but any measures resorted to which were designed to heal the patient. The judge who wrote the decision said: "If these magnetic treatments have no therapeutic effects, they may keep a patient from seeking medical advice in time to save him, while if they do produce therapeutic effects, they ought to be under the control of thoroughly competent persons." The decision of the highest court of the country will be awaited with interest.

CORRESPONDENCE.

THE ANNUAL REPORT OF THE LOOMIS SANITARIUM—DR. STUBBERT'S REPLY TO A CRITIC.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—In the MEDICAL NEWS of January 7, 1899, appeared a review of the Annual Report of work done at the Loomis Sanitarium for Tuberculosis at Liberty, New York.

Our duty in the administration of such sanatoria is to present in as concise a form as possible the results attained, thus giving to the medical profession the experience gained in peculiarly good clinical fields. With this object in view the facts in the report were offered as usual in statistical form. The writer was, therefore, surprised to see the critic first set his lance against statistics, especially when, he later on indirectly quotes statistics in support of a proposition of his own. We quite agree with the critic that "Very few men are able to handle statistics," being familiar, as we are, with the usual methods in vogue in hospitals. Data recorded by constantly changing junior members of a house staff must of necessity render statistics built upon such spasmodically constructed foundations inaccurate. At the Loomis Sanitarium the writing of all histories and the compiling therefrom of all statistics, is entrusted to *one qualified person* who has been with the institution from the day of its opening, and than whom, I do not hesitate to assert, no more competent and trustworthy statistician can be found.

The critic objects to the term *cured*. Until this year we used the term "apparently cured" but changed it for the former at the request of certain members of the Medical Board. We must differ with the critic in the opinion that there is no just criterion of cure other than *time*. A physician in private practice draws his conclusions from patients seen at intervals, *not* having them under constant observation, as has the physician in a sanitarium. Moreover, he has not the means of making as careful tests; therefore, his conclusions certainly cannot be more accurate. Reasoning by analogy it is fair to assume that a patient of 1896, having through progressive stages arrived at the condition of "apparently cured" and having maintained that condition since, notwithstanding his return to his former environment and work, a patient of 1898, having progressed through the same stages to the same condition, can be fairly assumed to be cured. In the way of positive evidence of a "cure" we also maintain that the disappearance of all physical signs of disease, of all rational symptoms, and finally of even the

shadow cast upon the fluoroscope should be sufficient evidence to satisfy the most hypercritical. Apropos of this statement we must inflict, with all due apology, additional statistics:

Patients discharged cured from June 15, 1896, to November 1, 1897, 19.

The number of whom we have lost trace, 7.

The number who may be fairly assumed to have remained cured (in the absence of contrary evidence), 19.

The number of whom we have positive evidence have remained cured, 12.

Total number discharged with disease arrested, 14.

Number lost trace of, 8.

The number who may be fairly assumed to have remained in this condition (in the absence of contrary evidence), 12.

Number of whom we have positive evidence have remained in this condition, 4.

Number who have redeveloped the disease (as far as we know), 2.

Those that may be assumed to have remained cured, 100 per cent.

Those that may be assumed to have remained arrested, 86 per cent.

Of these two classes the number of males was 13.

The number of females was 20.

All of these cured and arrested patients have been away from the Sanitarium for periods extending over from 1 to 2½ years. All of the cured patients, with the exception of 3, have returned to their former work and environments. These three have entered the Nurses Training School of the Loomis Sanitarium, and have worked constantly from the time of their discharge; they have been called upon to work at irregular hours night and day, and have been allowed only the short vacation of the school. They have shown absolutely no signs of a return of their disease. So much for the critic's objection to lack of sufficient time being allowed to elapse, etc.

We will now give the number of patients discharged cured or arrested from the opening of the Sanitarium until November 1, 1898, all of whom have been away at least three months.

Number discharged cured from June 15, 1896, to November 1, 1898, 47.

Number of whom we have lost trace, 13.

Number who may be fairly assumed to have remained cured (in the absence of contrary evidence) 46, or 98 per cent.

Number of whom we have positive evidence have remained cured, 33, or 70 per cent.

Number who have redeveloped the disease (as far as we know), 1, or 2 per cent.

Of the arrested cases, numbering 25, 22, or 88 per cent., may be assumed to have remained in that condition, and 3, or 12 per cent., have redeveloped the disease. We have lost trace of 13, and have positive evidence that 9, or 36 per cent., have remained arrested cases.

The critic again says, "We must ask the director why he makes no distinction between male and female patients, for it is well known that phthisis is far more fatal in the female than in the male." We reply by challenging his statement. German statistics lately compiled show that the two sexes are about equally prone to succumb to the disease. Our experience tends to show that while the sedentary life of woman makes her more susceptible to infection, her condition allows her more promptly to place herself within proper environments for recovery of health, thus more than counterbalancing the handicap. The only just ground for giving a comparatively unfavorable prognosis to women would be the danger from child-bearing. The following statistics from the Loomis Sanitarium sustain the above statement:

Number of patients discharged cured and arrested from June, 1896, to November, 1898, 72:

Males, 29, or 40 per cent.

Females, 43, or 60 per cent.

Again, of the 77 patients discharged unimproved during this same period, 44, or 57 per cent., were males; 33, or 43 per cent., females.

To the objection raised that the term "discharged improved" is too indefinite, we will have to exercise our prerogative as a Yankee by replying with the question, "What can you suggest that is better?" If a patient, after being advanced somewhat on the road to recovery, is compelled by personal or financial reasons to return home, he must be classified as improved, since his condition has neither grown worse nor remained stationary.

The critic cannot understand the statement that absence of high winds is popularly supposed to be a desideratum in the location of abodes for consumptives. I venture to say that if he puts the question to all physicians in New York City, and 100 of his lay friends, a majority of the former and nearly all of the latter will reply "protected sites facing the south." Again, the critic says we do not state whether we have followed the 27 per cent. of cured patients under serum treatment since their departure from the Sanitarium. We know positively that 17 have remained in the condition described as "cured" and none to our knowledge have redeveloped the disease. All these 17 patients have been away from the Sanitarium for periods varying from 6 months to 1½ years.

Finally, we wish to state that of all our patients discharged cured, none have been compelled to seek other than their former homes and climates; all, with the exception of the three nurses above noted, have resumed and continued their former vocations, and to our knowledge only one has shown any further signs of tuberculosis.

J. Edward Stubbert, M.D.,
Physician in Charge.

Loomis Sanitarium for Consumptives,
Liberty, Sullivan County, N. Y.,
January 20, 1899.

Cinematograph Exhibitions of Surgical Operations.—The latest craze in Paris is for postprandial exhibitions of surgical operations by means of the cinemetograph. Upon a recent occasion the guests at one of these entertainments were roused to great indignation upon recognizing a distinguished lady of Paris as the subject.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

A YEAR'S RECORD OF TYPHOID FEVER IN PHILADELPHIA—THE ANTI-VIVISECTION SOCIETY'S MEETING—UNITED STATES QUARANTINE VESSEL "PROTECTOR"—PAPILLOMA OF THE OVARIES—POSSIBLE URINARY TEST FOR OBSTRUCTION OF THE PANCREATIC DUCT—SKIAGRAPHS OF DERMOID CYST AND CALCULUS—A MEDICAL SOCIETY'S LOSS—MEDICAL SOCIETY NOTES—PERSONAL.

PHILADELPHIA, January 31, 1899.

DR. J. HOWARD TAYLOR, Medical Inspector of the Board of Health, last week submitted his annual report, in which he draws attention to the enormous increase in the number of cases of typhoid fever which have occurred during the past year, notwithstanding the distribution by the board of circulars warning householders to boil all water used for drinking purposes. This record of 1898 is enough to arouse public condemnation of councilmen who continue to allow the city to suffer from this preventable disease by failing to remove a system whereby water is supplied which has received human excreta from all manner of people in every condition of ill-health.

It is hard to believe that in these days 4749 cases of typhoid fever can occur in any city of a civilized country with a population no larger than that of Philadelphia, a city well regulated in that there is comparatively little, if any, overcrowding or tenement life among the poor. This morbidity has never been approached during the past decade, and in only one year, 1889, has it exceeded 4000 cases, the general average for nine years, excluding 1889, being about 2700 cases per year. To the 4749 cases of this year must be added 1348 soldier patients who were brought to this city. When the mortality is considered, however, a satisfactory and decided decrease is to be found, for there were 639 deaths, which is a mortality of 10.48 per cent. Since the year 1890 a decreasing mortality has been constant, beginning with 21 per cent. in that year, 19 per cent. in 1891 and 1892, 18 per cent. in 1893, 16 per cent. in 1894 and 1896, 17 per cent. in 1895, and 13 per cent. in 1897.

The Anti-Vivisection Society of America held its annual meeting in this city on Friday, January 28th. The usual harangues were indulged in, and the proud boast made that $3947.33 had been collected during the past year, of which $1000 was raised by a fair held here last month, and $1000 was a legacy left by Helen B. French, eaving not quite $2000, which this valiant band collected. The total expenditures, however, would seem to prove this amount more than necessary, for only $874 was spent, leaving a balance of more than $3000. This hardly proves the truth of a statement by that champion of champions, Mrs. Caroline White, who implies in a recent letter to a medical journal that lack of money prevents the Society from turning its attention to the cruelties of shipment of cattle rather than to scientific vivisection. Dr. Albert Leffingwell seemed to be the only speaker at the meeting whose views were at all moderate. He said his aim had always been to restrict rather than abolish vivisection, though he regretted to say that physiologists and scientists had lately come to think that there should be no limits to experimentation. Reference was made to the anti-vivisection bill now before Congress, and members were asked to devote all their efforts to ensure its passage.

The balloting for officers resulted in the election of the following: Dr. Matthew Woods, president; three vice-presidents from Pennsylvania and nine from Philadelphia; Miss Adele Biddle, secretary; S. H. Thomas, treasurer; Mrs. Richard P. White, corresponding secretary, and Miss Elizabeth Somers, assistant secretary.

The United States quarantine vessel "Protector" left here for Havana on Saturday last. She carries two sulphur furnaces, steam ventilating fans, a large jacketed steam chamber, light formaldehyd generators, and bichlorid-of-mercury tanks. The "Protector" contains also eight baths and a number of rooms for isolation, etc. The vessel will be used for the disinfection of vessels leaving Havana for United States ports and will be under the supervision of the Marine Hospital Service.

At a meeting of the Pathological Society held Thursday, January 26th, Dr. Henry L. Williams presented specimens from a case of papilloma of both ovaries with ascites. The fluid removed from the abdomen measured 23½ pints and nearly a gallon more escaped to the floor. Dr. Williams stated his belief that papillomata tend to recur in a malignant form frequently with metastases and Dr. Riesman in discussing the case said that if any variety of tumor could be thought of as possibly parasitic in origin, the papilloma seemed to be the one most likely. Dr. Wilmer Krusen reported a case similar to Dr. Williams' in which, one year after he had removed the ovaries for papilloma, the entire abdomen had become the seat of a malignant infiltration.

Dr. A. O. J. Kelly spoke at length of histologic technic and demonstrated the use of apparatus. He confined himself principally to a discussion as to the relative value of paraffin and celloidin methods of infiltration of tissue and showed photographs of an apparatus devised for the purpose of keeping celloidin preparations free from the moisture contained in the air. For this purpose he uses a wire shelf, placed in an ordinary specimen jar, under which calcium chlorid is kept. The discussion brought out different views as to the value of various infiltration methods. Dr. W. M. L. Coplin and Dr. David Riesman said they had never experienced any difficulty in keeping celloidin for an indefinite time in ordinary bottles well stoppered, and Dr. Williams said he had tried the calcium-chlorid method which had proved unsatisfactory.

Dr. A. C. Taylor drew attention to a possible urinary test for observation of the pancreatic duct which had been called to his attention by a case in which, in this condition, there was a marked diminution in the ethereal sulphates

Dr. Wadsworth exhibited some skiagraphs of tabetic arthritis, a dermoid cyst, and a calculus. The first showed that skiagraphy is of little import in this condition but calculi can be judged as to their density by the resistance offered to the X-ray. The dermoid cyst was shown fairly well by the skiagraph though it did not

clearly indicate its character: the cyst itself was also shown and contained several teeth and some bony material.

The Cambria County Medical Society suffered a severe loss from a fire which occurred last week. The Waters' block at Johnstown was destroyed and in it were the laboratories of the society which had recently been donated by the late Dr. J. M. Toner. The Toner library containing about 8000 medical works, some of which were very rare, was also destroyed causing a pecuniary loss of about $30,000, with no insurance.

The Lehigh Valley Medical Association met at Bethlehem on January 26th. Dr. Charles M. Ott, Director of the Packer Memorial Hospital at Sayre, presented a paper on "The Importance of Early Operation in Tuberculosis of Bones and Joints"; Dr. Olin F. Harvey one on "Some Peculiarities Found in Examining Applicants for the Regular Army," and Dr. G. Betton Massey of Philadelphia, one on "The Advantage of the Cataphoric Method of Destroying Cancerous Growths."

At a meeting of the Pediatric Society, held January 10th, the following officers were elected: President, Dr. Edwin E. Graham; vice-presidents, Drs. Alfred Stengel, D. J. M. Miller, and Thompson S. Westcott; secretary, Dr. Alfred Hand, Jr.; treasurer, Dr. H. B. Carpenter; recorder, Dr. D. L. Edsall. Executive Committee, Drs. S. M. Hamil, J. P. Crozer Griffiths, Frederick A. Packard, John H. Jopson, and George Woodward.

Dr. David Riesman has been appointed by the Board of Trustees of the Philadelphia Polyclinic and College for Graduates in Medicine Professor of Clinical Medicine. Dr. W. H. Parish has been appointed Medical Director of St. Agnes' Hospital. Dr. John T. Carpenter, at one time President of the County Medical Society and of the State Medical Society, died at his home in Pottsville on Sunday, January 22d.

The total number of deaths occurring in Philadelphia for the week ending January 28th, as reported at the Health Office, was 518, of which number 133 occurred in children under five years of age.

OUR LONDON LETTER.

[From Our Special Correspondent.]

H. R. H. ON BOTH SIDES OF THE FENCE—ANOTHER HONOR FOR LORD LISTER—DARING RESCUE FROM THE FUMES OF HYDROCYANIC ACID—H. I. M. CONFERS ADDITIONAL HONORS UPON THE MEDICAL PROFESSION—SO-CALLED AMERICAN IDEAS AND AMERICAN INVENTIONS.

LONDON, January 17, 1899.

THE inconveniences of royal personages as patrons of reform has been forcibly illustrated during the last few days. Only a couple of weeks ago H. R. H. the Prince of Wales was presiding over a public meeting of the Society for the Prevention of Consumption, and thus pronouncing the benediction of "good form" upon its crusade. Last week his name appeared at the head of a petition presented by the Smithfield Market Club *against* the abolition of private slaughter-houses, which is one of the cardinal items in the propaganda of the first-named society. Indeed, all sanitary reformers and progressive citizens have been urging this step upon the London County Council for months, and thought they had almost succeeded in securing its action. The explanation is simple enough. The sporting tastes of the Prince are well known, and evidently, in the language of the Bowery, some other "dead-game sport" has worked upon the good nature of His Royal Highness to prostitute his name and influence in this extraordinary fashion. The painful question, of course now arises, Had he any clear idea of what he was doing when he presided at Marlborough House two weeks ago?

The council of the Royal Institute of Public Health has awarded the Harlien Gold Medal for distinguished services to preventive medicine for 1899 to Lord Lister. He certainly deserves it, and a hundred like it, if mortal man ever did, but it looks a trifle like "gilding refined gold and painting the lily."

Great enthusiasm has just been excited by the heroic rescue of five persons by a young corporal of artillery, William Hall, from imminent death by influences which have a curious medical, or at least materia-medical, interest. The young children of an electroplater named Grimme, got into his workshop during his absence and upset a can of cyanid of potash into a shallow tank full of sulphuric acid. The fumes from this cheerful mixture prostrated all three of the children before they could even reach the door, and their mother and a shop-boy who came to their assistance shared the same fate. Mr. Hall, who was passing in the street, saw the crowd at the bottom of the staircase, and dashing bravely into the deadly fumes rescued all five of the victims, one after the other, although he was so nearly overcome that on his last trip he fell unconscious, and would have been suffocated had not his brother come to his assistance. The curious evanescence of the poisonous effects of hydrocyanic acid is illustrated in the fact that in spite of their prolonged immersion in its fumes every one of the victims recovered within a few hours, and next day declared themselves as feeling actually none the worse for their terrible experience, except some nervousness.

Who can longer say that no good thing can come of alcohol? Lord Iveagh, whose superb donation to the Jenner Institute has made him the hero-benefactor of science for the year, is a member of the firm of Guiness & Co., the great Dublin brewers of "pale ale" and "Dublin Stout" fame. Still, we can hardly claim all his philanthropy as due to his alcoholic environment, for much of it is hereditary, his father, the founder of the firm, Sir Benjamin Guiness, having been a great public benefactor of his native city, Dublin, and his brother, Lord Ardilaun, having just united with him to clean up nearly a square mile of slums in the heart of the city, and rebuild it as a model ward for working men, with sanitary cottages, public baths, a recreation park, and a concert hall with permanent orchestra. This will cost another quarter of a million pounds. The father was knighted, and the two sons raised to the peerage on account of their great wealth and the public-spirited use

they made of it. Thus is the English aristocracy recruited.

And speaking of honors of this description, the list of the New-Year's gifts just made by Her Majesty contains at least two names that all the American profession will be glad to see there. One is Sir Henry Thompson, well known for his lithotomy and lithotrity work, who is raised from a knighthood to a baronetcy, and the other, Dr. Herman Weber, the climatologist, who is knighted, probably chiefly for the yeoman service he has rendered in the crusade against tubercle.

Inasmuch as the only difference between a knighthood and a baronetcy is that the title "Sir" is in the latter inherited, as Sir Henry Thompson has no son, the new honor seems rather an empty—we will not say a "baron"—one in his case, although, of course, the satisfaction of writing "Bart." after one's name and title is supposed to be something. A Dublin physician, Dr. Plunkett O'Farrell, is also knighted, and "orders" of various sorts (conferring the right to wear a broad blue ribbon suspending an elaborate piece of jewelry round one's neck upon State occasions) are granted to no less than thirteen other medical men, chiefly of the Indian Medical and Colonial Services.

The London County Council is taking a view of its civic responsibilities which is of great sanitary interest and value. Much has been done in the way of breaking up slums by driving new and broad streets through and getting rid of tenement-rookeries by tearing them down to make space for public buildings or breathing-spots, but it has always been a complaint of workers among the poor that nothing was done to provide the wretched tenants who were turned out into the street by these means with new and better quarters. Thus, it was stated, they simply drifted away into other decaying neighborhoods to form new slums.

This view has had weight with the Council, which has recently come to the decision that in future whenever rookeries are torn down for the public good, an equal tenant-accommodation shall be provided in the form of model tenements or cottages, either in the near neighborhood or upon some alternate site at municipal expense. At this rate the slum will soon be as extinct as the dodo, and the death-rate shrink to even smaller dimensions.

A most singular form of sponging upon the good nature of physicians is alleged to exist by a prominent London paper. In some reflections provoked by the death of Sir William Jenner, it declares that it is by no means unusual for fashionable West-End physicians to not only attend *gratis*, but even to financially assist in floating certain of their aristocratic but impecunious patients, presumably for the sake of the "advertisement" of their illustrious patronage, and possibly their recommendation to others of "the swell set." We can scarcely credit the story, but after all is there anything more absurd in paying for the privilege of attending distinguished personages for the sake of "reputation" than in attending humble individuals for the same reason? The alleged custom is well characterized by the *Graphic* as "West-End pauperism."

Much sportive comment has been provoked both in the press and in society by the humorous remonstrance addressed to novelists by the *Medical Press* on the serious danger of their depopulating the world of fiction by the terrible preponderance of the death-rate over the birth-rate in their pages. The *Press* has been gathering statistics and reports that in some forty of the most popular novels taken at random the deaths are to the births recorded as *ninety-six* to one!

Dickens is given honorable mention as the least flagrant offender, while Anthony Hope is awarded the bad eminence of the most reckless one, for his "Prisoner of Zenda" has an average of five deaths per chapter, and not a single birth in the whole of it. Not even the prospect of one, for it notoriously fails to end with the time-honored formula "and they were married and lived happily ever after." Various considerations have been urged in extenuation that Anthony Hope, for example, is a bachelor, that children are seldom interesting except to their parents, and, lastly, what is most pertinent for our consideration, that a number of the accused authors are Americans, and "children are going out of fashion in America." It is astonishing how strong a hold this last impression has gained upon the popular mind, nearly every device for the prevention of conception or production of abortion is described as an "American" invention.

Vaccination since its desertion by the law is receiving support from an unexpected source. The trustees of the great Peabody model dwellings, who control the rooms of more than 11,000 working men, insist upon vaccination as one of the first conditions of tenancy. A few days ago a laborer who had been a tenant for four years availed himself of the notorious "conscience clause" in behalf of one of his children, and received notice to quit within twenty-four hours.

Appreciation of the value of the doctor in school-work is steadily growing. Of thirteen lecturers at the winter session of the Royal College of Preceptors, three are doctors, and the London School-board has just appointed four physicians to deliver courses of special lectures upon the proper use of the voice and care of the throat.

A most singular cause of death has just been reported at a coroner's inquest here. The seven-month's-old child of a hair-dresser was sitting playing with its toys when its father, who sat just behind, suddenly sneezed violently. Instantly the child started, fell back in its chair in convulsions, and died in a few minutes. The doctor who was called testified that he could find nothing amiss with the child except some traces of a recent bronchitis, and that death was due to heart-failure. The description strongly suggests "*thymus tod.*"

And now even "Phossy Jaw" of sensational fame may be placed upon the banners of the Consumption Crusade. Dr. Stockman of Glasgow has just reported the examination of the pus from six cases of phosphorus necrosis, and that he found tubercle-bacilli present in every case. Furthermore, upon investigating the records of a large number of fatal cases, he found that a large majority of the patients died of pulmonary tuberculosis, and that gener-

alized tuberculosis, intestinal tuberculosis, and meningitis were not uncommon. Rabbits exposed with injured teeth to the fumes of phosphorus died in six weeks of tuberculosis, but those kept in sterilized hutches and protected from contagion resisted the fumes almost indefinitely.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Ninety-third Annual Meeting, Held at Albany, N. Y., January 31, and February 1 and 2, 1899.

FIRST DAY—JANUARY 31ST.

MORNING SESSION.

THE meeting was called to order by the President, JOHN O. ROE, M.D., of Rochester. REV. MR. SYLVESTER offered prayer. The President then delivered his

INAUGURAL ADDRESS,

There appeared before the board representing the Medical Society of the State of New York 809 applicants for licenses; before the homeopathic board, 36; and before the eclectic board, 24; making a total of 869. Of those appearing before the board of the Society 24.9 per cent. were refused. The rejection by topics were: anatomy, 55; physiology and hygiene, 41; chemistry, 67; surgery, 54; obstetrics, 62; pathology and diagnosis, 68; therapeutics, practice, and materia medica, 78.

That medical charity is most wantonly abused no one will deny, or question the necessity of correcting this abuse in the best and most effective manner possible. A bill has been recently formulated and presented to the Legislature, which is, we believe, the best that has yet been prepared, as it gives the medical profession equal representation with the laity in the chartering and management of these institutions, under the control of the State Board of Charities. Section 5 of chapter 4 of the by-laws of the society says: "There shall be a standing Committee on Legislation, consisting of three members, the duties of which shall be to watch the course of State Legislation on medical subjects, and to take charge of such matters pertaining to medical legislation as shall be referred to it by this Society. All proposed legislation offered by any member of the Society, and all resolutions touching medical legislation shall be referred to this Committee, which shall make a report thereon to this Society as soon as possible. It shall also, at each annual meeting, report to the Society any laws relating to medical matters that shall have passed during the year." If the wording of the by-laws is to be construed that this committee is only to look on or take notice of the legislation affecting medical subjects then the committee is entirely useless and the duty is merely perfunctory. It is recommended that this be revised.

The advisability of granting licenses to midwives is questionable for if we grant to them the special privilege of practising medicine to this limited extent, we will have to admit the justice of the claims of the opticians, osteopaths, Christian Scientists, and the dermatological quacks. It is recommended that this question be placed entirely under the control of the State Board of Medical Examiners.

The medical laws of this State at the present time are eminently satisfactory and entirely adequate to rid the State of every illegal practitioner if they were enforced. The difficulty lies in the laxity of their enforcement. It is especially discouraging to students in medicine to spend years in study and hard work to fit themselves to pass the requirements of the Examining Board, when these illegitimate practitioners and quacks are allowed to go unmolested.

The antivivisection bill has been before Congress for two years, and its passage urged by its fanatical advocates, and the representatives of various humane societies. That vivisection should be prohibited by law from being practised by persons having no interest in science, or for the gratification of a morbid curiosity, there is no question, and that if it is frequently abused no one will deny; but when rightly conducted, vivisection teaches science many valuable lessons. The inconsistency of these myopic fanatics cannot be better illustrated than by the alacrity with which they will go from their convention halls to their rods and guns to gratify their desire for sport by torturing the poor fishes with their cruel hooks, and destroying the lives of harmless birds and noble animals, or inflict mortal wounds from which they die a lingering and agonizing death. Marvelous advances are made in serum-therapy; but still these cranks would rather see their children die of diphtheria than to have the means of prevention discovered by comparatively painless methods of animal experimentation.

The extent to which the adulteration of food is carried on in this country is estimated by the Agriculture Department to affect $700,000,000 of food-products annually. That is, the people of the United States are defrauded to that extent. Bills for the prevention of this adulteration of food and drugs has been introduced in Congress. One called the Faulkner Bill, and the other, the Brosius Bill. Every National or State organization should appoint a committee to cooperate with the Committee of the National Pure Food and Drug Congress, to bring about the passage of these bills.

DR. HENRY R. HOPKINS of Buffalo read the report of the committee on hygiene. The total mortality of our army of industry for the year is 124,600; 12,370 of this number were deaths from accidents and old age, and the remaining 112,230 deaths show the difference between our hopes and our realization. The mortality from diseases known to be communicable is 19,510; add to this deaths from consumption, 13,257, known to be communicable, equals 32,767. Add to this the next largest single group of deaths from acute respiratory diseases, 17,106 and we have a total of 49,873, representing deaths from diseases most probably communicable and, therefore, preventable.

DR. J. M. VAN COTT of Brooklyn, Chairman of the Committee on Prize Essays, reported that no essays had

been presented, probably on account of the smallness of the prize offered—$25. A motion was then made and carried that the money should be held over for three or five years, and then offered as a prize, since the amount then might stimulate competition.

DR. CHAUNCY P. BIGGS of Ithaca presented a paper on

FRACTURE OF THE CERVICAL VERTEBRÆ, WITH SPECIMEN.

A man, aged seventy-five years, of remarkable strength and vigor, by the sudden starting forward of his horse was thrown from his wagon, striking on the ground upon his head. He was rendered helpless from the moment of injury. Whether complete paralysis occurred at the time or not was not known. He suffered more pain from the ride from the scene of injury than at any time after. Two surgeons from New York were called in consultation, who pronounced the injury one of fracture of the cervical portion of the spine about the sixth or seventh vertebræ with a dislocation backward. The finger introduced into the mouth discovered a prominence in the pharynx. The peculiar nature of the fracture was found later to be different from the conception expressed by these two doctors. The specimen shown proved that the canal was not obliterated, but that the injury to the cord resulted from a spicule of bone that penetrated it. The marked and characteristic deformity in the pharynx was due to the crushing of the upper end of the upper fragment and not to any dislocation; this prominence was situated below the seat of injury and not above it. The cord with the spicule of bone was exhibited; also, the spinal column. It was believed that the crushing of the body of the fifth vertebra resulted from the blow upon the head, and the fracture of its arch was the result of the blow upon the back of the neck. The points of special interest in the clinical history were the clear, clean-cut condition, the exact lines of anesthetic areas, the complete paralysis of all the muscles which received their nerve-supply below the injury, the subnormal temperature, and the freedom from any urinary infection. The flexors of the arm and the diaphragm were the only muscles not completely paralyzed below the point of injury.

DR. W. D. GARLOCK of Little Falls presented a paper on

AN UNUSUAL INJURY TO THE KIDNEY, WITH SPECIMEN.

A healthy man, thirty-one years of age, while engaged in a game of base-ball, was run into by a fellow-player, and forcibly struck on the left side between the eleventh and twelfth ribs. The blow completely prostrated him, and he suffered greatly from shock, but was not rendered unconscious. He was moved several times, and the first physician he saw gave him a hypodermic of morphin, finding him in marked shock, pale, with moist skin, feeble pulse, and a temperature of 97° F. No tumor or dulness was noted. The urine was clear, and there was no difficulty in micturition. The next morning he passed a very small amount of bloody urine, and he then stated that he passed a very small amount after the accident. Shock was still present, and there was some dulness and tympany. Twenty-six hours after the receipt of the injury there was marked distention, shock, and evidence of growing tumor in the left kidney region. Operation was advised and consented to. Evidences of peritonitis were found when the abdomen was opened, and there was blood in the peritoneal cavity, and the omentum was found to be torn across. Over the site of the left kidney a subperitoneal tumor was noted, while posterior to the kidney a large amount of blood was found. The large amount of lacerated injury done the kidney necessitated its removal. Three hours after the operation the patient died.

DR. WILLIAM H. PARK of New York read a paper on

FORMALDEHYD DISINFECTION.

(This article will appear in a future issue of the MEDICAL NEWS.)

DR. ERNEST WENDE of Buffalo read a paper with the title

THE DANGERS OF THE LONG-TUBE NURSING-BOTTLE.

This long tube in the nursing bottle is a prolific source of cholera infantum. No better incubator could be devised for the development of germs. Milk is the favorite food of bacteria. These tubes render this favorable for the development of organisms, and conditions are here present for the production of this dreaded disease. Experimental work was conducted upon various tubes taken from different drug-stores. These tubes were found to be of more than one layer, and these layers were connected together by pits; the material was very porous; these little cavities favored the propagation of germ life. Elevations and depressions were shown by microphotographs. It is obvious that the ordinary methods of cleansing cannot remove the danger. The kind of bacteria found were noted, especially the staphylococcus pyogenes aureus. Segments of the rubber tube was placed in an incubator for five days to disintegrate them, and experimental studies then made, and the conclusions justified the opinion that milk and rubber, as existing in these nursing-bottle tubes, are prolific of great danger.

DR. A. WALTER SUITER of Herkimer, as a result of the investigations of Dr. Wende, offered a resolution, which was carried, that the Medical Society of New York procure the enactment of laws to prohibit the sale of long tubes in nursing-bottles.

AFTERNOON SESSION.

The following nominating committee was appointed by the President: Drs. J. B. Ransom, Wendell C. Phillips, William Browning, H. Bendall, Eugene Beach, O. C. Eastman, Edward Meany, M. P. Conway, and Ernest Wende.

DR. WILLIAM G. BISSELL of Buffalo then read a paper on

THE DETECTION OF TUBERCULAR INFECTION IN SECOND-HAND CLOTHING.

His conclusions were based upon the result of investigations carried on by him in the Health Department of

Buffalo, regarding tubercular infection. In connection with military duties, his attention had been called to the fact that several members left the organization on account of tuberculosis. At that time the uniforms and overcoats, when discarded by an out-going member, were assigned to the next new recruit. According to his views, these uniforms of men who had contracted tuberculosis were capable of transmitting that disease to the next wearer. He conducted a series of experiments to prove this. Uniforms were secured, their pockets removed and labeled; they were then washed, and the resulting washings were placed in a centrifugal machine until a sediment was obtained; this sediment was diluted and injected into sixteen guinea-pigs; seven of these died of acute septic disturbances; of the nine remaining animals, five recovered, but two of these died later of tuberculosis. The animals which contracted tuberculosis contracted it through the inoculation of material obtained from the pockets of the discarded uniforms. This proves the great danger of communicating tuberculosis by clothing worn by consumptives.

DR. H. R. HOPKINS of Buffalo then offered a resolution, which was carried, that the Society approve the matter of municipal control of dealers of second-hand clothing and refer it to the Committee on Legislation.

DR. W. L. CUDDEBACK of Port Jervis presented a paper on

INTESTINAL RESECTION: PERSONAL EXPERIENCE,

in which he related his experience in dealing with a case of strangulated hernia, with complications following, necessitating the resecting of the intestine by means of the Murphy button; the abdominal cavity was afterwards flushed.

DR. ROBERT H. M. DAWBARN of New York spoke in regard to using the Murphy button for end-to-end anastomosis. The button might be left behind, necessitating a secondary celiotomy for its removal, as occurred in the experience of Dr. Wyeth of New York. Other methods he considered equally rapid. The second point which he criticised was in regard to washing out the abdominal cavity. It is now the practice among New York surgeons not to wash out but to wipe off; of course, if there is a general suppurative involvement, or feces in the cavity, irrigating the cavity must be done. It is the unanimous opinion that wiping should be resorted to rather than irrigating.

DR. WILLIAM C. KRAUSS of Buffalo then offered a paper on

THE CLOSE RELATION BETWEEN THE NASAL AND THE CRANIAL CAVITIES AND BETWEEN NASAL AND CRANIAL DISEASE.

After speaking of the anatomy of these parts he referred to the old idea that the watery secretions often found running from the nose come from the brain; this idea he did not think to be altogether fallacious, on account of the close relationship between these cavities. He thought there is a direct aeration of the brain, and through the nasal cavities there is a ventilation of the brain, especially of the frontal lobes. In cases of obstructions it has been found that the portion of the brain on that side was not so well developed as on the unobstructed side. To prove his assertion he referred briefly to the case of a girl, whose mental functions developed rapidly, and she seemed bright and active up to a certain age, when she became stupid and dull and could not learn anything. The doctor suspected adenoids. Adenoids were found and an operation performed, and in the space of a few months she took her place with children of her own age and is now as bright and active as any of her companions. It was the obstructed nasal ventilation which caused her condition. The effect of this temporary nasal obstruction is often seen, causing imperfect brain action. The nose is the cavity of the body most often exposed to infection; it serves as a filter of germ life and is, therefore, a nidus for their development, being a hospitable abiding place for them; here they have warmth and moisture, and the nasal mucous membrane contains many bacteria.

The statistics of Buffalo show that in 1893 there were 239 cases of death from cerebrospinal meningitis; in 1894, 244; in 1895, 219; in 1896, 186; in 1897, 207; in 1898, 181. The statistics carefully made shows only two diseases that have a greater death-rate than cerebrospinal meningitis, *i.e.*, tuberculosis and phthisis. It is very prevalent in Buffalo, and has a very high death-rate, and is especially prevalent during the first half of the year, at the time when there is more nasal trouble. He desired to plead for a more careful attention to the nasal mucous membrane. Lotions are hardly ever applied to this the most filthy of all the cavities of the body. Children should be taught to wash out the nasal cavities regularly as they are taught to brush their teeth. For cleansing Dobell's solution is most satisfactory of all; it should be used warm and in small quantities, and be followed by the use of liquid vaselin in small quantities.

DR. CLARENCE C. RICE of New York, read a paper on

THE IMPORTANCE OF EARLY EXAMINATION AND TREATMENT OF CATARRHAL MOUTH-BREATHING IN THE PUBLIC SCHOOLS.

Ninety per cent. of the class of cases termed "mouth-breathers" in children are not simple ailments of catarrhal disease of the nose but are evidences of obstruction which prevents nasal respiration. This obstruction is largely due to the presence of enlarged tonsils. It is impossible for children to clear their nostrils by blowing, for the post-nasal space is completely blocked. Most authorities do not recognize the fact that ninety per cent. of mouth-breathing occur in children as a result of this cause. Small hypertrophies in this situation produce a chronic rhinitis and a general catarrhal condition. Enlargement of the post-nasal tonsil is often a very important factor. To diagnose this the finger is a very unreliable guide unless the physician has made many such examinations. The doctor makes a diagnosis with the post-nasal curette if he cannot use the mirror, this being often impossible in fractious children. With the curette the vault is found to be slippery as glass or polished wood; no tissue can be

taken away; if there is a soft, spongy tonsil it can be pulled down with the curette. It is much easier to use the curette than a finger in the small space in small children. In nine to ten per cent. of older children there is some enlargement of the posterior nasal tonsil, frequently small but often of most importance. It is present in sixty per cent. of all deaf-mutes. The importance of these lies in the fact that mouth-breathing is neglected in school children. The presence of this condition in school children is a constant menace to their companions. Decomposing nasal secretions cause an acute rhinitis, etc., and every physician who treats many of these cases has difficulty in keeping his own nose in good condition; he must neutralize his own nasal passages. The medical inspectors in schools in New York do not look for mouth-breathers; they look for the commencing signs of infectious diseases. Mouth-breathing should also be looked after.

DR. ROBERT H. M. DAWBARN of New York read a paper on

HOW TO TREAT SHOCK.

(To appear in a future issue of the MEDICAL NEWS.)

DR. B. FARQUHAR CURTIS of New York presented a paper on

FEVER IN ASEPTIC SURGERY.

(To appear in a future issue of the MEDICAL NEWS.)

DR. A. T. BRISTOW of Brooklyn presented a paper on

THE USE OF ANTITOXIN IN PHLEGMONOUS INFLAMMATIONS, WITH A REPORT OF CASES.

(To appear in a future issue of the MEDICAL NEWS.)

DR. CARLOS F. MACDONALD of New York read a paper on

PUERPERAL INSANITY.

Ninety per cent. of cases of insanity assume the maniacal type; ten per cent. are quiet and more or less prolonged. He then briefly considered the causes of mental aberration. The immediate and direct cause is malnutrition. It is the duty of every physician to familiarize himself with the various causes in order that he may be enabled to combat this trouble. Insomnia is an unfavorable accompaniment and should always be considered as such especially when accompanied by constipation and suppression of the lochia. As regards the prognosis, the pulse is an important guide; when it is below 100 or even 106 a favorable result may be recorded as regards life. A rapid pulse indicates gravity and should make one circumspect as regards opinion. There is no specific in the treatment of this condition. Manage and treat each patient on general principles, looking out for functional troubles, such as sleep and innutrition. As regard hypnotics, sulfonal, chloral hydrate, and many others are used. Sulfonal is hypnotic and sedative in action. In puerperal melancholia we have a valuable remedy in opium. Extract of cannabis indica is valuable, especially when a diuretic effect is desired. If involution is not complete the fluid extract of ergot in dram doses is good; and one should remember that in insanity larger doses are required than in health. Food should be given at regular intervals; if food is refused forced feeding must be resorted to by the stomach tube. One should keep in mind the fact the insanity is an exhausting disease calling for highly nutritious food.

DR. HENRY A. FAIRBAIRN of Brooklyn read a paper on

CARDIAC DEGENERATION AS EXEMPLIFIED IN THE SOLDIERS OF THE LATE WAR.

DR. R. H. HOPKINS of Buffalo, presented a paper on

HYGIENIC CAMPS,

in which he gave the statistics of deaths from explosives, from wounds, and from disease in the Crimean War, the War of the Rebellion and in the late Spanish--American War.

EVENING SESSION.

DR. GEORGE W. BRUSH of Brooklyn presented a paper on

THE RELATIONS OF PREVENTIVE MEDICINES TO POLITICAL ECONOMY.

The States should take more active measures to prevent the spread of consumption. Until recently little has been done by the State. The highest duty of the State is to secure the welfare and happiness of its inhabitants by the preservation of the health of its citizens. Without health the productive power of the citizens is lost to the State. In any case of disease whose propagation could be prevented, it would be a crime not to make an effort to stop its mortality. The New York State Board of Health has taken active measures in stamping out infected meat and milk. While work has been done in this line, little has been done to prevent disease in the human race. At the last session of the Legislature a special committee was appointed, of which the speaker is the chairman, whose duty it is to found sanatoriums in the Adirondacks for tuberculous patients. The committee made careful research, and recommended that hospitals for the treatment of this disease be founded; it also recommenced the wise dissemination of literature treating of the subject, realizing that much can be done to prevent the spread of this disease in that way. It is well-known that hospitals for the care of consumptives among the poor do not wish to take in the poorer classes; this is an astonishing statement to make, but it is only too true. Ordinary hospitals will not want these cases among the poor, so they are driven back to the tenements, and so assist in disseminating this disease.

There are three phases to be considered: First, the humanitarian aspect; second, the duty of the State to protect its individuals; third, the economic aspect. The speaker advised a wider dissemination of knowledge of this disease among the people, especially as regards disinfection. This dissemination of knowledge and the establishment of hospitals certainly demands prompt attention at the hands of the legislative bodies of this and other States. Only one State—Massachusetts—in the Union has established such a hospital during the past year.

DR. J. H. PRYOR of Buffalo read a paper, entitled

THE RELATION OF THE CONSUMPTIVE TO THE STATE.

(It will appear in a later issue of the MEDICAL NEWS.)

DR. WILLIAM HAILES, JR., of Albany showed a series of

MICROSCOPIC PROJECTIONS.

With the usual magnification of a one-half-inch lens he was able to demonstrate very clearly all the important features of the cellular human tissues. The position of the projected picture and its focussing on the screen the lecturer could change for himself by a system of three rods attached to the projection apparatus and leading to the position near the screen where the lecturer stood. Dr. Hailes announces the appearance in the near future from a well-known optical firm of a projection apparatus that will demonstrate to large audiences microscopic slides with the details of a one-twelfth-inch oil-immersion lens.

DR. LOUIS A. WEIGEL of Rochester read a paper, entitled

THE X-RAY FROM THE STATIC MACHINE AND SOME PRACTICAL POINTS IN MEDICINE AND SURGERY.

Among other things shown were: Skiagrams showing that the amount of cartilage present around children's joints makes it extremely difficult, practically impossible, to diagnose fractures in these regions in the young by means of the X-rays. A skiagram of a case in which pain around the hip-joint developed in a child during the course of typhoid fever, with disturbance of the joint relations and shortening was presented. The condition was diagnosed as one of tuberculous hip-joint disease for years until the skiagram showed that it was a dislocation of the head of the femur on the brim of the acetabulum. The case was evidently one of those rare spontaneous luxations of the hip that sometimes occur during the course of typhoid. They have been studied recently, especially by Keen.

A bad comminuted fracture at the wrist was shown in skiagram. The diagnosis of the real condition was only possible by the X-rays and was very easy then despite the presence of a great deal of swelling and a bandage. It was cut down upon and an excellent functional result obtained considering the circumstances. A skiagram subsequent to recovery, however, still showed, as might be expected, marked deformity. Such a skiagram if taken by a court of law, without the clinical history, might seem absolute evidence of bad surgery. As a matter of fact in this case it was really evidence of the best conservative and scientific surgery since the case was such as is often thought a proper subject for amputation.

Skiagrams were exhibited showing that glass is opaque to the X-rays almost as much as is bone. They were taken to demonstrate that there was absolutely no foundation for a threatened damage suit in which the patient claimed that her surgeon had failed to remove all the fragments of glass from wounds in her hand made by a broken pane of glass. In the patient's hand the X-rays absolutely failed to show the presence of pieces of glass.

Skiagrams showed suspicious transparency of bone over a tender point in bone suspected to be a tuberculous focus, so that the X-rays may prove a valuable diagnostic agent in the very early stages of bone and joint tuberculosis. In anchylosis skiagrams were shown from which the advisability or not of operative intervention could easily be decided, and whether the anchylosis was bony or fibrous demonstrated.

DR. G. W. WENDE of Buffalo, read a paper on

CERTAIN RARE SKIN DISEASES ILLUSTRATED BY STEREOSCOPIC PROJECTIONS.

Among the notable cases pictured were parakeratosis, an atrophic skin lesion, that so far has been observed only in Italy and America. It consists of a depressed patch of skin, with abrupt hard edges, in the floor of which the natural folds of the skin are obliterated. It is progressive and leads to the obliteration also of the cutaneous glands, etc., in the area affected.

A case of favus affecting in huge patches the non-hairy skin was shown. Kaposi had had a similar case, with gastro-intestinal symptoms, which had proved fatal, and at the autopsy the lesions of favus were found in the intestines. This case also proved fatal after intestinal symptoms, but only a very incomplete autopsy was allowed by the family, and no lesions of the digestive tract were found.

Stereograms of a case of rhinoscleroma was shown that had gradually progressed to fatal issue. It is of special interest as occurring in a child of twelve of American parentage, who had always lived in Buffalo. Injections of salicylic acid into the diseased tissues, as recommended by Professor Lang, had been tried but seemed to do more harm than good. The case was a most typical example in all its symptoms, in its evolution, and final fatal issue of this rare disease which has been hitherto considered not to occur in this country.

A picture of multiple idiopathic pigmented sarcoma was exhibited. Kaposi states that the prognosis of this disease is the worst possible and that the duration of the disease is usually not longer than three years. Sections of the diseased tissues showed the characteristic appearance of sarcoma. Notwithstanding this and the bad prognosis, large doses of Fowler's solution were followed by the complete disappearance of the lesions and the patient has now been for a year without any symptoms of the disease. This same experience has followed the use of Fowler's solution for this disease in other patients.

Photographs of a serious case of X-ray dermatitis wer exhibited which had followed a half-hour's exposure to the X-rays. The original erythema had taken nine days to develop into an ulcer that gradually spread over most of the dorsum of the foot and had been accompanied by intense pain. The painful element had always clung to the affection. The most sedulous and continuous care had failed so far to secure entire healing of the lesion. When seemingly almost well it broke down again. It is now more than a year since the origin of the lesion and there is still an open ulcer and the patient is yet unable to put his foot upon the ground because of the pain caused by the intensely irritant character of the lesion.

SECOND DAY—FEBRUARY FIRST.

DR. R. W. WILCOX of New York read a paper on

CHLORIN IN THE TREATMENT OF ENTERIC FEVER.

(It will appear in the next issue of the MEDICAL NEWS.)

Officers for the ensuing year were elected as follows: President, Dr. Willis G. Macdonald of Albany; vice-president, Dr. John Gering of Auburn; secretary, Dr. Frederick C. Curtis of Albany; treasurer, Dr. Charles H. Porter of Albany.

SECTION IN SURGERY.

FIRST DAY—FEBRUARY FIRST.

DR. HERMAN J. BOLDT of New York read a paper on

THE TREATMENT OF UTERINE HEMORRHAGE WITH STYPTICIN.

This drug, he said, is a derivative of narcotin, one of the alkaloids of opium. Its action on the circulation resembles in many respects that of hydrastinin. The scope of the remedy may be indicated by the fact that improvement followed its adminstration in peri- and parametritis after abortion and full-term deliveries, in some cases of menorrhagia associated with chronic oophoritis, menorrhagia in virgins presenting no evidence of pelvic disease, and in cases in which curettage had given only very temporary relief. Stypticin may be given either by the mouth or subcutaneously. By the former method the dose should be 3 decigrams or less.

DR. SEYMOUR of Utica said that he had long been of the opinion that the curette is used unnecessarily often and that medicine would frequently give better results.

THE RELATIONS OF MOVABLE KIDNEY AND APPENDICITIS TO EACH OTHER, AND THE PRACTICE OF MODERN GYNECOLOGY.

DR. GEORGE M. EDEBOHLS of New York read this paper. As a result of long practice with his original method of palpating the appendix he has come to the conclusion that chronic appendicitis is present in between 80 and 90 per cent. of women with symptoms resembling movable right kidney. Four per cent. of all women have appendicitis and 3½ per cent. have both appendicitis and symptoms resembling movable kidney. Movable left kidney never produces appendicitis. He has been able in more than one instance to observe the development of movable kidney and appendicitis. Much valuable information may be gained by making it a routine measure to palpate the appendix before undertaking abdominal operations.

CONSERVATIVE TREATMENT IN DISEASES OF THE OVARY AND VERMIFORM APPENDIX.

DR. ROBERT T. MORRIS of New York read this paper. After adverting to the important functions of the ovaries he spoke of the sad results which often follow operations on the ovaries with only imperfect knowledge of the conditions confronting the surgeon. Regarding appendicitis he said that various surgeons have succeeded in securing a death-rate of only a fraction of one per cent. by early operation in cases in which the infection had not extended beyond the appendix, and a death-rate of about five per cent. in cases in which the infection had spread further. This was contrasted with the death-rate of more than twenty-five per cent. from all forms of medical treatment of appendicitis.

DR. A. PALMER DUDLEY of New York spoke of his own conservative work on the ovaries, now embracing 114 operations. He had been able to collect statistics from these patients showing eighteen pregnancies and twelve living children. This seemed a sufficient justification for such conservative work.

(To be continued.)

THERAPEUTIC HINTS.

Relief from Itching Due to Bites of Insects and Vermin is said to be obtained if several repeated applications of formalin be made to the spot, the fluid being allowed each time to evaporate. The smarting caused if the spot by excoriated is relieved by water. The soothing effect is immediate, and beyond a hardening of the skin no objective results will be noted.—*Gonin.*

The Rigidity of the Perineum.—SOUTHWORTH claims that local application of the following mixture will effectually hasten the relaxation of a rigid perineum during labor:

℞ Chloroform . . . . . parts 2
Etheris } aa . . . parts 1.
Eau de Cologne }
M. Sig. External use.

For Bronchitis and Pulmonary Congestion.—Occurring in the course of grip in children, the following formulæ are recommended, the internal treatment being aided by the application of sinapisms and dry cups to the back:

1. ℞ Tinct. aconiti . . . gtt. v–x
Sodii benzoatis . . . gr. xv–xlv
Syr. lactucarii . . . *m.* xv–℥ iiss
Syr. aurantii flor. . . ℥ v
Mucilag. acaciæ . . . ℥ iv.
M. Sig. Two teaspoonfuls every two hours.

2. ℞ Ext. cinchonæ . . . gr. xxx
Terpin hydratis . . . gr. xv
Spts. vini gallici . . . ℥ v.
Syr. aurantii flor. . . ℥ i
Aq. melissæ . . . ℥ ii.
M. Sig. Two teaspoonfuls every hour.

For Erythematous Lupus. — UNNA frequently employs medicated collodion painted over the affected area from two to four times a day. The collodion used for the preparation must have a neutral, not an acid reaction.

℞ Saponis viridis . . . . parts 2–4
Collodii flex. . . . . parts 20.

℞ Saponis viridis } aa . . parts 2
Ac. salicylici }
Collodii flex. . . . . parts 20.

To be used if the skin shows much irritation:

℞ Ichthyol . . . . . parts 5
Collodii flex. . . . . parts 20.

ORIGINAL ARTICLES.

THE TREATMENT OF TYPHOID FEVER BY CHLORIN.[1]

BY REYNOLD W. WILCOX, M.D.,
OF NEW YORK;
PROFESSOR OF MEDICINE AND THERAPEUTICS IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; PHYSICIAN TO ST. MARK'S HOSPITAL.

FOUR years ago I presented a paper upon this subject before this Society. At that time I brought out the fact that several of the accepted ideas in regard to the effect of chlorin were erroneous. I showed that it was not entirely changed into chlorids in the stomach or blood, and excreted as such by the kidneys, nor was it irritating to the mucous membrane of the alimentary tract. I reported at that time the histories of four patients who had been under observation, and the results conclusively showed the beneficial effects of chlorin. During the time which has elapsed since my first report, if I may judge from an extensive correspondence with physicians, the statements which I made have been accepted. My purpose to-day is to briefly review the present status of the treatment of typhoid fever, and to report a series of cases illustrating the beneficial results which can be obtained in apparently desperate instances of this fever. Yet during the time which has elapsed every one who reads attentively the literature concerning the treatment of enteric fever must be impressed with the vigor and persistence with which the advocates of cold bathing argue for their pet method.

While I am willing to admit that under certain circumstances and conditions cold bathing may be of advantage in enteric fever, I may be pardoned for subscribing to the statement cleverly presented by a recent writer that "while it is written that man shall not live by bread alone, it should also be added that all diseases are not cured exclusively by cold water." Yet in all the literature upon the use of cold water there seems to be a glaring ignorance of the real history of this method. You are well aware that this method of treating typhoid fever has been named after Brand. As a matter of fact it is extremely difficult to understand why this should be so. Historical accuracy demands that to James Currie of Liverpool belongs the credit of the introduction of the cold-water treatment in fevers. Nor, indeed, can the argument be maintained, which is occasionally advanced, that the method was not strictly determined either in its procedure, or in its indications or contra-indications, owing to the lack of use of the clinical thermometer, for it is a matter of fact that Currie was one of the first in England to make use of the clinical thermometer, being even the inventor of an index which would facilitate its more accurate reading. Yet it is true that for all that Currie's observations date back to 1786, it was not until six years later that he made use of the thermometer systematically. For all that Brand's paper was published in 1861 it was not until five years later, *viz.*, 1866, just eighty years after Currie's observations were made that cold-water bathing attracted much attention, and, if we would wish to be accurate as to the facts, the method—if method it be, should not be called the Brand treatment of typhoid fever, but credit should be given to Jürgensen of Tübingen who pressed the claims of this method upon the profession. Accuracy, then, demands that it should be called the Currie-Jürgensen method. Nor should we forget that R. W. Matthewson, Nathan Smith the elder, and Hiram Corson were strong advocates of the use of cold water in the treatment of typhoid fever long before the subject had attracted attention upon the Continent.

The history of this method is a curious one, and inasmuch as my experience began and mainly ended before any of its present high-priests, apostles, and propagators were acquainted with it, I may be pardoned for briefly alluding to the various theories which have been advanced. In the early period of the use of this method it was advocated because it was thought it reduced that great bugbear of the time, the fever. When it became apparent to any one who carefully observed his patients that its effect upon the fever was transient, that almost as frequently the temperature rose after the bath as fell, this theory of its use became untenable and was abandoned. But the devotees of the bath continued to tub their patients without any theory. Later the patients were subjected to the bath on the ground that it was a wonderful nerve stimulant, and those of us who see most of it are willing neither to affirm nor deny the truth of this hypothesis for it has the merit of most gratuitous hypothesis in that it can neither be disproved nor proved. With the fall of

[1] Read at the Ninety-third Annual Meeting of the Medical Society of the State of New York, held at Albany, January 31, and February 1 and 2, 1899.

the theory of nervous stimulation the baths continued just the same, for the second time without a theory. The last and present theory of the use of the baths is that they increase the elimination of ptomains. The baths certainly are diuretic, but that they eliminate ptomains is at present incapable of proof, for the simple reason that at this present moment we have no method by which ptomain-elimination can be accurately measured. It has been said that the urotoxic coefficient increases after the bath, but how is this determined? By the injection of urines from patients into different animals! Now it is true that certain animals are more susceptible to the toxic influence of urine of animals of other species, and the determination of the urotoxic coefficient by this method rests solely upon the behavior of the test-animals after injections of these urines. Inasmuch, also, as the intravenous introduction of urine even of animals of the same species is an inexact demonstration it is evident that this test is absolutely fallacious. It is perfectly safe at the present time to say that until chemistry shall afford us a method of obtaining quantitative and qualitative results as to the toxins found in the urine all theorizing as to the increased urotoxic coefficient must be absolutely worthless as a guide to clinical procedure. Even granted that the Currie-Jürgensen method does eliminate toxins, would it be more than a simple makeshift in the presence of the fact that the real treatment of enteric fever is the treatment directed to the cause and not to the effects of the disease?

While I have no intention of criticising a method which for its simplicity, rigid rules, and accurate dosage leaves no incentive for the practitioner but to travel in the narrow road of a disease and an assumed remedy, it is time, I think, to call a halt and consider whether we cannot in ways far more pleasant and, to say the least, quite as efficient, deal with patients suffering from this disease. The brute force of statistics is always thrust forward to convince us that cold bathing is the panacea, the begin-all and end-all of the treatment of typhoid fever. That even the brute force of statistics fails of effect is shown by the remarkable results obtained under all forms of treatment under all sorts of conditions in the late Maidstone epidemic.

Death from typhoid fever can take place (1) from general causes, such as toxemia, pyrexia, or paralysis of the heart; (2) from local lesions which are peculiar to typhoid fever, such as perforation and hemorrhage; (3) from intercurrent affections, as pneumonia. Following Sidney Phillips, I believe that we are justified in saying that pretty nearly one-half of all the deaths are due to the second and third causes. If the statistics of Hare of Australia prove anything they prove conclusively that the number of deaths from perforation and hemorrhage so far from being reduced by the use of cold water is increased by it. Deaths in the third group, from intercurrent affections, are relatively small. It is evident, then, that if the Currie–Jürgensen method is effective, it should be effective in diminishing the number of deaths from general causes. The claim, then, that this method reduces the mortality from seventeen or eighteen to eight or nine per cent., if true—and it may possibly be—it means that eighty-two out of every hundred who would recover even without the bathing and the nine who will die with or without bathing, *i. e.*, ninety-one out of every one-hundred patients, are subjected to routine bathing unnecessarily and that the nine who die have these repeated baths added to their suffering. The difficulty of administration of cold water, to use an extreme term, the cruelty to the patient involved in its use, is practically to be ignored if this method offers better opportunity for cure. For my part, after an extended experience, I have never felt that it did, or that it was possible that it should, by any process of reasoning based upon the rules of logic. On the other hand, from the time that typhoid fever was recognized as a distinct disease, and more particularly when it was demonstrated by Eberth to be of bacteriologic origin, the eliminative and antiseptic treatment has been first and foremost in the minds of advanced clinicians. The question never has been as to the advisability of the antiseptic treatment in typhoid fever—that is self-evident. The only questions which have arisen have been, first, Can the antiseptic treatment be efficient? and, second, How shall we best secure its efficiency?

The use of chlorin is not new. It did not originate with me nor with Burney Yeo, for both of us derived our information from the same source, *viz.*, the practice of the physicians in India. I have felt that in the early stages of the disease we could treat many patients effectively by the use of such insoluble antiseptics as bismuth naphtolate and various preparations of salicylic acid, and by naphtalin, believing that in this way the vitality of the bacillus of Eberth might be inhibited, and the patient go on to satisfactory convalescence. An extended experience with the disease has shown me that a very considerable number of patients suffering from demonstrable typhoid fever do recover under this treatment in a period shorter than the assigned time for its course without ever having experienced evidences of marked systemic poisoning. On the other hand, I am aware that Sanulli is strongly of the

opinion that in this disease the intestinal lesions are the result of the action of the toxins circulating in the organism infected by the germ of Eberth, and that this is the principal cause of the material manifestations and morbid phenomena which go to make up the clinical picture of typhoid fever. If this be true, then an antiseptic which can be disseminated so far as the blood goes, and which can permeate every organ and every tissue is the prime necessity.

Probably no more difficult series of typhoid patients ever presented themselves than the soldiers who returned from the late war. With typhoid fever introduced in the camps of instruction, soldiers herded together in camps selected in utter disregard of the prime essentials of a healthy location, where every precaution as to water-supply and camp sanitation was disregarded, transported into a climate in an expedition improperly equipped, led into a campaign by a foolhardy commander, herded in unsanitary transports, returned to a camp in a region which for 250 years man has attempted in vain to inhabit, these men, half-starved, half-clothed, over-worked, and uncared for, furnished most striking examples of what official inefficiency and medical incompetency can do the human being. These patients did not suffer from typhoid fever alone—it was starvation *plus* typhoid fever, and when they were brought to the city to hospitals large numbers of them were either delirious or comatose, emaciated beyond recognition, the symptoms resembled septicemia rather than enteric fever, so that the problem of restoration to health was by no means an easy one. If there ever was a test for any method these conditions certainly furnished a severe one. In all the instances which I have recorded the diagnosis was confirmed by the Widal reaction.

CASE I.—McD., twenty-two years old, was in Puerto Rico from July 27th to September 11th. Eight days after his return the symptoms appeared. He came under my observation on October 1st, having been treated from September 19th by various methods, bathing, quinin, hydrochloric acid, oxgall, etc. His temperature at no time had been less than 102° F., in spite of all the methods, except immediately after some of the baths upon the 26th, 27th, and 28th of September, when there was a fall for a few hours, followed by a rise to a higher level. From this time to October 14th his temperature remained between 100° and 102° F., or over. Upon the 14th chlorin water was administered in dram doses every three hours, with the result that upon the 16th, two days later, his temperature reached 99.2° F., rose that evening to 100° F., and gradually subsided until his discharge, on the 28th, with a normal temperature. During the period of chlorin administration, in this and the subsequent cases, we made use of alcohol sponge-baths, and the patient was given milk with as much pure water as he cared to drink, an accurate measurement being made of all fluids taken in the twenty four hours, as well as the amount of urine passed during that period. This patient presented symptoms such as I had not seen since my student days—the apathy, the coated tongue, the tympanites—yet his convalescence was rapid and definite.

CASE II.—R. S., had been under observation since September 12th, when he was found to be comatose, so that no history could be elicited. From the first his temperature had been persistently from 103° to 105° F., no method of treatment having been apparently of any avail. He had run the gamut of remedies usually employed in typhoid. On October 4th the chlorin treatment was begun. The lowest point reached since he came under observation was on the 6th, when his temperature was 99° F., with a rise to 101° F. in the evening. His temperature gradually fell reaching normal on the 13th, when convalescence was established.

CASE III.—M. D. took part in two battles in Cuba, was about fifteen days in trenches, became sick about a week later, suffered from diarrhea, was returned to Montauk Point, and was treated by various methods. On September 8th his afternoon temperature was 104° F. and on the 10th, 106.2° F.; then a few days of subnormal temperature followed. His temperature followed such an irregular type that the blood was examined and plasmodium found to be absent. After a period of comparatively low temperatures on October 13th the patient suffered from a relapse, his temperature reaching 104.5° F. in the afternoon and 105° F. in the following afternoon. At this time we administered chlorin-water, with the result that normal temperature was reached upon the morning of November 2d and under the continuance of this remedy never rose above 99° F. The patient was discharged well on November 8th. During the early part of his treatment and up to the time of the relapse it was considered that he was progressing as well as could be expected so no antiseptic treatment was instituted.

CASE IV.—M. H., seen September 25th. No history was obtained as the patient was delirious. His temperature on admission was 104 6° F., running very irregularly, being with one exception over 101° and generally about 104° F. He had a severe hemorrhage on October 2d. Quiet and the ice-coil upon the abdomen kept the patient in a fairly comfortable condition. The temperature oscillated between normal and 101° F. during the process of his disinfection, which was commenced on the 6th. On October 11th the afternoon rise being less than one degree his medication was omitted. On the 14th pneumonia of both lower lobes developed and the usual course of pneumonia followed, reaching its culminating point on the 17th and gradually defervescing. Inasmuch as the stools during the latter part of the month, the 30th and 31st, were offensive and the patient suffered from tympanites and had a

temperature of from 100° to 101° F. chlorin was again given. Normal temperature was reached on the 15th and convalescence continued until he was discharged on the 27th of November.

CASE V.—G. O. came under observation on September 5th apparently in the early stages of the disease. The various methods were used without any apparent effect upon the progress of the disease, cold baths and alcohol sponging seeming to be equally inefficient, and the disease ran its usual course until October 5th, when the patient presented the usual characteristics of the third week of typhoid. On the 7th the evening temperature was 103.5° F. At this time chlorin treatment was begun. Normal temperature was reached on the 9th and from that time on until the 19th his temperature never reached 100° and was generally about 99° F. On the 19th there was a sudden rise to 103° F. and a very careful examination of the abdomen and the general symptoms showed no cause for it. Inasmuch as a rise of this kind is extremely rare when the patient is under chlorin treatment and is never due to any recrudescence of the disease but to some accidental or complicating condition a very vigorous search was instituted and it was found in a phlebitis of the left femoral vein. Under appropriate treatment this subsided gradually and the patient was entirely well in the early days of November.

From these and a very considerable number of patients whom I have seen I believe that there is in medicine nothing more striking than the clearing up of the tongue, the improved mental condition, and the lessened local disturbances and the general betterment which chlorin brings about when administered to these patients presenting the severer forms of the disease. I have presented these histories very briefly for the sole purpose of pointing out that the use of this remedy is not contraindicated by the severity of the disease nor the hopelessness as regards the patient's recovery. These have been, in fact, the most severe instances of typhoid fever which I have seen in the last twenty years. After four years of observation I am ready to reiterate the conclusions which I presented to you in my former paper, *viz.:*

1. That in the treatment of typhoid fever chlorin can be safely administered until complete disinfection of the alimentary canal is obtained.

2. Under its use the tongue becomes cleaner, the appetite and digestion better, the fever lower, and the stools devoid of odor save that due to chlorin.

3. The general strength, intellectual processes, and nervous conditions improve.

4. The disease is shortened in duration and the patient usually proceeds to a rapid and complete recovery.

THE TREATMENT OF HEADACHE.

BY JOSEPH COLLINS, M.D.,
OF NEW YORK;
PROFESSOR OF NERVOUS AND MENTAL DISEASES IN THE POST-GRADUATE MEDICAL SCHOOL; VISITING PHYSICIAN TO THE CITY HOSPITAL.

(Continued from page 134.)

THE variety of headache known as habitual headache, or idiopathic headache, has very little in its location, or in the character of the pain to differentiate it from neurasthenic headache, and as has before been said, it is not improbable that it is in reality a manifestation of this disorder, although usually none of the somatic or psychical concomitants of nervous exhaustion are to be found.

Traumatic headache is so obviously dependent upon injury, and so usually attended with its objective accompaniments that it requires no further mention. When persistent and rebellious to treatment, its association with localized pachymeningitis, or even graver diseases of the intracranial structures should be borne in mind.

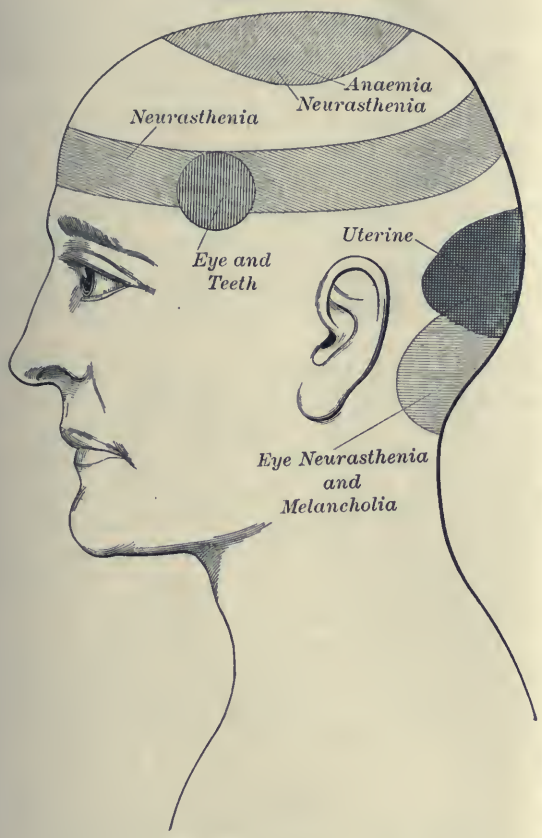
Rheumatic epicranial myositis is of more frequent occurrence than one would be lead to suppose from the scant reference to it in the literature. It is accompanied by headache and the same features as myositis in any other part of the body, and by such it is to be diagnosticated.

Much help in the proper interpretation of headache may be obtained from a careful consideration of its location. Not that headache due to an individual cause, such as eye-strain, for example, is always referred to the same area in the head, but if an average of all the cases of headache associated with such a condition is taken it will be found that the pain is localized by the sufferer either in the frontal or the occipital region. Instead of giving verbal description of the location of headache as a diagnostic indication, use is made of the accompanying diagrams (Figs. 1 and 2), which are based on diagrams originally published by C. L. Dana. It should be borne in mind that these are somewhat schematic, and that the headache of a given area does not necessarily confine itself there, or manifest itself there on every occasion.

After all that has been said concerning the character, duration, seat, intensity, and diagnostic significance of headache, it may seem superfluous to pursue further the subject of diagnosis, but as the correct interpretation of headache is of paramount importance in determining the successful treatment, it may not be amiss to say a few words more on this important phase of the subject. After the symptom has been considered from the points of view that have been mentioned, the

eventual diagnosis should be reached by process of exclusion. The first thing to do is to exclude the cephalic pains of neuralgia and of migraine. The pain which we speak of as neuralgia of the trigeminal nerve, and of the occipital and the upper branches of the cervical nerves is to be distinguished, first, by its location in these nerves and along their course; secondly, by the character of the pain, which is often of a sharp, unbearable kind, relatively persistent; that is, without periods of intermittency, and continuous for a long time; thirdly, by a sensitiveness of the epicranial structures, including the hair, to which these nerves are distributed; and, fourthly, by the fact that this variety of cephalic pain is almost always relieved, temporarily at least, by hot applications.

Fig. 1.



Showing approximate locations of pain in headache.

Migraine is to be distinguished by the location of the pain, usually confined to one side of the head; by its association with nausea or vomiting; mental depression; vasomotor disturbances of the face, either flushing or pallor; hemianopic obscuration of vision, by flashes of light, phantasmagoria, or scotomata; vertigo; ringing in the ears; and occasionally with paralysis of one of the oculomotor nerves, all of which symptoms are made worse by the slightest physical or mental effort. They are often ameliorated, especially in overworked and intensely neurotic people by taking small quantities of predigested or easily assimilated food and by diffusible stimulant in small quantities.

After the neuralgic pains and migraine have been excluded, it becomes necessary to establish the fact that the cephalalgia is not due to disease of the epicranium and of the cranial bones and their cavities, such as rheumatic myositis, periostitis, caries, inflammation of the frontal sinuses, etc. The first can be excluded by the local manifestations and by the association of other symptoms of rheumatism and uricacidemia. Caries of the cranial bones and periostitis, be they syphilitic or traumatic, will be accompanied by etiologic or symptomatic features that distinguish them, while the location of headache due to catarrh of the frontal sinuses, its association with disordered intonation, and its accompaniment of unilateral nasal discharge, will prompt the diagnosis. The headache of ethmoiditis, which is more common than generally supposed, is generally of a neuralgic nature, located in the frontal and intra-orbital regions, and accompanied by unilateral or bilateral swelling which is palpatable on either side of the root of the nose.

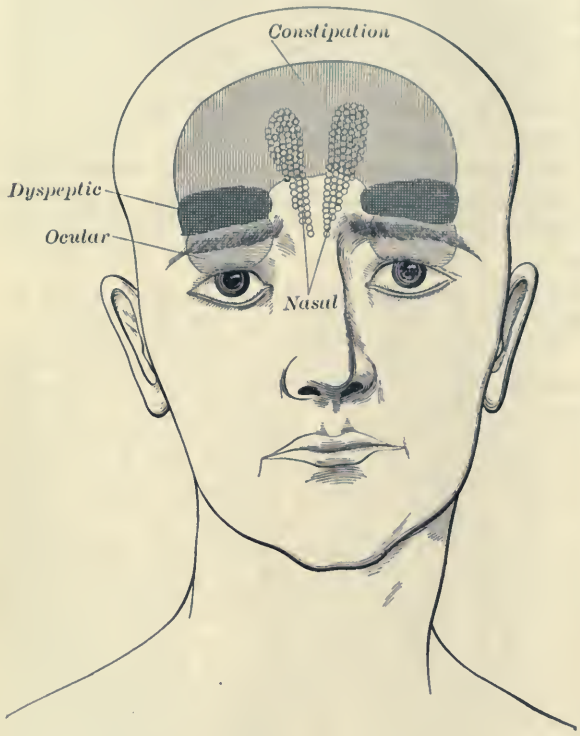
Because headache is often the initial and the most conspicuous symptom of disease of the brain and meninges, painstaking care should be taken to exclude these diseases. Although headache is weighty above everything else in suggesting the presence of such disease, it is only when in association with vomiting, delirium, vertigo, convulsions, spasticity, nuchal rigidity, paralysis, and inflammation or atrophy of the optic nerve determined ophthalmoscopically that it has such dread import. After the process of exclusion has been brought thus far in the estimation of the kind of headache, it behooves us to give consideration to the organs of special sense, particularly the eye and the nose, and to determine if there be anomalies of refraction, muscular insufficiency, or organic disease of the eye, such as glaucoma, on the one hand, or anything encroaching on the nasal passages on the other.

Finally, the circulatory apparatus and the blood should be investigated, after which sources and evidences of intoxications and infections, both within and without the body, are passed in review, leaving for final consideration the elimination of the neuroses, neurasthenia, epilepsy, and hysteria. It is not unlikely that when one is done with this painstaking process he will find that the last one considered is the category to which the headache belo ngs. Having his labor for his pains, he may console himself

with the German proverb: "Uebung macht der Meister."

Considering all that has been said concerning the multifarious causation of headache and the extremely disparate conditions under which it occurs, it is not at all surprising that no individual or specific method of treating it exists. There is no ailment in the domain of medicine that requires more careful, searching investigation to elicit its causation and nature than headache. In order to treat it successfully, the physician must determine the morbid indicativeness of the symptom, then adopt measures which combat it. There seems to be a sort of traditional belief that certain drugs are more or less

Fig. 2.



Showing approximate locations of pain in headache.

specific for headache. Implicit credulity of this kind accounts in part for many uncured headaches. At the present day, when it is so easy to relieve pain temporarily by the administration of common analgesics, the temptation of the physician is to prescribe in routine fashion some of these temporizing agencies, reposing confidence that Nature will do the rest; while the habit of the patient is to go to the drug-shop and buy a headache powder. Although it is a just and legitimate procedure to quell pain promptly and at all hazards, it is no less incumbent upon the physician to strive for the prevention of the recurrence of such pain. The treatment of headaches offers a splendid field for the indulgence of such endeavor, and he who contents himself with giving phenacetin, antipyrin, the bromids, and the like, without seeking the ulterior cause and attacking it is predestined to failure, while doing both the patient and himself an injustice. The first duty when confronted by a patient suffering from headache is to determine to which of the four categories enumerated in the beginning of this article it belongs. Is it migrainous, neuralgic, symptomatic, or idiopathic headache? It is extremely necessary to make this distinction, for although the treatment of one variety may not be absolutely dissimilar to that for the other, the recognition of its belonging to one of these classes may immediately orient one not only in regard to treatment, but as to prognosis as well. The next step in the treatment is to determine the disease of which it is a symptomatic accompaniment. Then its treatment can be legitimately undertaken. To pass in review, even though briefly, the measures that have been recommended for the relief of this common disorder would be bewildering and unprofitable. I shall, therefore, speak only of measures with which I have had personal experience.

In brief, the treatment of headache presupposes the correct etiologic diagnosis, which in turn depends upon a searching examination of every system of the body, and especially those that experience has taught us to stand in frequent relationship to this symptom, and the utilization of temporizing measures. The latter are of very great value, and, fortunately, few in number. They may be conveniently referred to in four groups:

1. Drugs that are derived from coal-tar distillation and synthetically, possessed of analgesic properties: phenacetin, trophenin, exalgin, salol, and combinations of these with alkalis, such as antikamnia, etc.

2. Drugs that are plant derivatives, acting principally upon the vascular system: caffein, cannabis indica, opium, etc.

3. Mineral compounds, such as the bromids, acting principally upon nerve-cells, and the salines, acting upon the circulatory fluids to produce watery evacuations.

4. Antispasmodics, and paralyzers of striped muscular tissue, such as etheral substances and belladonna.

It is often necessary to give one or more of the constituents of these four classes; it matters not what the form or causation of the headache may be. Speaking generally, it may be said that those of the first class may be relied upon to produce an amelioration of the pain in all headaches, save those due

to inflammatory disease, and to pressure. Those of the second group are particularly serviceable in headaches accompanied by marked deviation of blood pressure, caffein being the symptom medicine par excellence in headaches associated with lower vascular tension, and cannabis indica in those associated with a pulse of high tension.

The symptom medicines in the third group have a much more confined application. The class represented by the bromids have their chief use in epileptic headaches and headache with vasomotor symptoms, while the salines are narrowly confined in their usage to the headaches of auto-intoxication. The drugs of the fourth-class are of use principally in headaches associated with spasmodic and fatigued action of peripheral muscular apparatus.

Unquestionably, the common form of headache that the general physician is called upon to treat in this country to-day, is, I think, that associated with the exhausted and irritable condition of the sympathetic and cerebrospinal systems known as neurasthenia. It is a variety of headache that is difficult to cure, especially the forms that develop in early life, and for which there seems to be no adequate determinable cause. These cases represent an inborn tendency toward neural instability. Headache which is a symptom of the neurasthenic state occurring in adult life and from determinable causes are usually very amenable to treatment, while those occurring in later life, particularly if they are the expression of a second or third attack of neurasthenia, are very rebellious. The treatment of these headaches is the removal of the causes and the adoption of measures directed immediately to the relief of the neurasthenic state. These measures comprise intelligent rest, exercise, change of environment, which may mean simply change from home to a boarding-house, or vice versa, increase of nutrition through diet, and hydric applications, and in some cases the use of massage and electricity. To take up in detail each one of these measures would be beyond my purpose. I shall refer only to the use of water, as this is the measure which is probably least understood. It is difficult to state in a few words the form of hydric procedure most beneficial to neurasthenic patients, but as a general rule it may be said that the application of water from 80° to 50° F. to the chest, abdomen, and back, from the hollow hand of an attendant, combined with friction during the application, and after the application if the patient does not react well, is the safest and most serviceable way of utilizing water when no apparatus is at hand. Where access is had to a hydriatic institute, it will be found that best results are to be had from the use of the ordinary douche, with water of 85° F., lowered one or two degrees each day until 50° F. is reached, and from ten- to twenty-pounds' pressure, followed by a Fleury spray, the water being of about the same pressure and temperature. The precaution should be taken to dilate the peripheral blood-vessels and start the sweat-glands to slight activity by incasing the patient's body in a hot box for from two to five minutes before the douche, making him walk briskly for from five to twenty minutes in the open air after the spray. Headaches, associated with increased vascular tension, flushing of the face, and throbbing sensations in the head, are often relieved by cold applications to the head, by wrapping the head in linen wrung out of cold water, and by the administration of a sitz bath, half bath, or a derivative foot bath. Neurasthenic headaches, associated with sleeplessness, are in my experience more quickly and wholesomely influenced by a full warm bath of from 96° to 102° F. to which from one to two ounces of pine-needle extract is added, and given just before retiring, than by any other measures. By a seeming contradiction in terms, rest for the neurasthenic patient often means considerable physical exercise, and the advent of golf and bicycling as fashionable indulgences have marked the rocks and bunkers on which many a neurasthenic headache has been shattered. The treatment of functional symptomatic headache, be it neurasthenic or hysterical, by electricity is not a fruitful subject for discussion. Occasionally headache of this kind that maintains stubbornness to every form of therapy succumbs to sparks from the static machine administered through a coronal electrode. Occasionally, also, the administration of a very mild galvanic current of from one-half to one milliampere and of five-minutes' duration, the positive pole at the back of the neck, the negative pole over the forehead, has been of some service in the headaches occurring with the repressed form of neurasthenia. The effect of the electricity is, I believe, to be attributed to suggestion. The medicinal treatment of neurasthenic, hysterical, and epileptic headaches is not so important as the general treatment save in the latter disease. In neurasthenic headaches associated with low vascular tension, caffein, either alone or in combination, gives excellent results. The following formulary I find particularly useful:

℞ Caffein citratis . . . . . gr. v
Sodii bromidi . . . . . gr. x
Sodii bicarb. . . . . gr. x
Pulv. acid. tart. . . . . gr. x.

M. Ft. pulv. No. 1. Sig. Take in water while effervescing.

Or,

Caffein salicylatis		gr. i
Ammonii salicylatis Phenol salicylatis	aa.	gr. v.

M. Ft. cap. No. 1. Sig. One capsule every three to four hours.

Or,

Caffein pur.	gr. ss. to gr. iss
Phenacetin	grs. v.

M. Ft. cap. No. 1. Sig. Take with hot water and repeat in one hour if necessary.

As a general pick-me-up and diffusible stimulant for neurasthenic headache, especially of women, the following prescription has served me well:

Ammonii carb.	ʒ iii
Tinct. sumbul	ʒ vi
Spts. lavandulæ	℥ i
Elix. ammonii valerian. ad.	℥ viii.

M. Sig. Two teaspoonfuls every three hours in water.

Naturally these remedies are symptom medicines and they suffice only for amelioration and temporary cure. The administration of general tonics and nervines should not be neglected. One of the most satisfactory mixtures that I use in the depressed forms of neurasthenia, especially neurasthenic and anemic headache, is as follows:

Zinc. phosphatis	gr. ¼
Ferri. redact.	grs. xx
Extract nucis vomicæ	grs. ii.

M. Ft. pill No. 8. Sig. One pill two or three times a day.

In headaches of a similar nature accompanied by a greater disturbance of the emotional life, that is, headaches having the character of neurasthenic headaches occurring in hysterical people, the following formulary can be recommended after a number of years' experience:

Zinci valerianatis Ferri sulphatis Ext. rhei. Asafœtidæ	aa.	℈ i.

M. Ft. pill No. 20. One pill three times a day.

Before taking leave of this part of the subject I wish to say one word concerning the use of bromids in the headaches of neurasthenia and hysteria. It will be remarked, no doubt, that very little mention has so far been made of the salts of bromin. And this for the reason that it is my belief, as it is the belief of many neurologists, that bromids have been done to death in these disorders. I have no intention to deny the utility of the bromids in certain forms of neurasthenic and hysterical headache, for personally I make some use of them; but nothing has been more impressed upon me from my intercourse with physicians of experience than the fact that the abuse of bromids, especially in functional nervous diseases is one of the burning evils of the time. There is no disease, with one and possibly two exceptions, these being epilepsy and migraine, in which it is justifiable to administer bromid for any considerable length of time. Nevertheless, it cannot be denied that many practitioners are either unwilling to subscribe to this view or they are heedless of such advice. There are certain cases of neurasthenic headache, especially those associated with general erethism and anorexia nervosum in which the administration of bromids for a few days is extremely serviceable and one or the most popular prescriptions at my clinic is the following, known as mistura nigra:

Sodium bromid	℥ ss
Pepsin scales	℈ ii
Pulv. veg. charcoal	ʒ iiss
Glycerin	ʒ ii
Spearmint water ad.	℥ iii.

M. Sig. Teaspoonful two or three times a day, after meals.

(To be continued.)

SPECIAL ARTICLES.

THE MEDICAL NEWS' INVESTIGATION INTO THE CLAIMS OF CHRISTIAN SCIENCE.

BY JOHN B. HUBER, M.D.,
OF NEW YORK;
ASSISTANT TO THE CHAIR OF PRINCIPLES AND PRACTICE OF MEDICINE IN THE NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.

(Continued from page 143.)

CASE XVIII.—Unmarried woman, aged forty-one years. Mother, now living, has been a sufferer from stomach trouble; after some time this trouble "went to her head." As a child the subject had gastric attacks and once membranous croup. During her fifth year she fell from a height and struck on the back of her head. When eight years old had spinal disease; severe pain between the shoulders and in occiput and in limbs when going upstairs. When aged thirteen had gastric attacks. In 1897 was treated by Dr. A. (R.) all winter. Symptoms generally began with water-brash; on dieting this would pass off. There was dull pain in gastric and umbilical region. She got along nicely under Dr. A. and discontinued treatment in April, 1880. Then she went to Brooklyn to live, where she went into collapse. In 1880 she was in a runaway and broke her arm; for five years after repair of fracture had arm massaged. Then more spinal trouble; cauterization was advised, but she would not consent to it. In 1882 she went abroad, having mental trouble and nervous prostration. During two years abroad she was better. On her return her stomach was as bad as ever. In 1887 she visited Dr. B. (H.) for irregular and painful menses, etc. After this she went to California where she felt well except for her back and a sore throat. Here heard of Christian Science, but did not take it up. In February, 1888, because of intense supra-orbital and orbital pain she consulted Dr. C. (R.) who examined her eyes and prescribed glasses, which she wore. They helped her sight but not her pain.

Distress in back got worse. In 1889 went into Christian Science; after ten-days' treatment she took off the glasses and has not worn them since. At first her eyes pained her; now they do not. Otherwise she feels well.

Dr. A. writes: "I took no notes of Miss X's. case at the time when she consulted me as she had no other than functional derangements with more or less hysterical accompaniments. She was inclined to exaggerate her symptoms and altogether was one who would very probably be cured by the right faith-cure."

Dr. B. has no notes and an indistinct recollection of this case; considers she must have been "a rounder."

Dr. C. writes: "Complains of pains in eyes and head. Has suffered and is suffering from extreme nervousness (neurasthenia). Eyes myopic; with correcting glasses has $\frac{20}{30}$ vision on each side. Atropin used and with correcting glasses vision $\frac{20}{20}$ on each side. Liked her glasses and was not seen again. Diagnosis: Myopia each side; no complications; general neurasthenia."

CASE XIX.—Druggist, aged about thirty years. Has been in Christian Science since February, 1897. Heard his wife read "Science and Health" and felt guilty. Had had "beliefs" of swearing and smoking; since having heard this reading he neither swears nor smokes. Had a "belief" of piles; denied he had piles. "Was a child of God and couldn't have piles"; now does not have piles. Had constipation: used to take constantly ox-gall, cascara, pepsin, calomel, etc.; now does not take medicine and does not have constipation. Before going into Christian Science he had accumulated a "greater medicine-chest than most physicians have," and had a library of medical books to which he used to refer when sick. Since being in Christian Science has thrown away or disposed of these and is now well with the exception of one thing. He had worn eyeglasses prescribed by Dr. A. for six years before going into Christian Science. He had had supra-orbital headache and difficulty in reading. Since February, 1897, he has not needed glasses and has no distress in reading. Once in a while he has severe frontal headache; he has not yet been able to get rid of this "belief"; this becomes worse when his mind is disturbed.

[Is still in the drug business, however.]

CASE XX.—Wife of subject of Case XIX, aged twenty-eight years. Married at the age of seventeen; first child when eighteen. Had been torn at this birth; nine months after Dr. A. (R.) on examination found the womb much enlarged. Was then much run down, but after nine-months' treatment by Dr. A. was in fair condition. Then at the age of twenty-one second child was born; cold in the breast and peritonitis followed this birth. Topical applications were made; "solution of acid" put in womb and as a result felt cold and rigid; was purple in face and hands; great pain. Then went to hospital where she was operated upon for laceration of the womb. After this she went for treatment to this hospital twice a week, where topical applications were made. Then got an idea she had some stomach trouble. Then learned from Dr. C. (R.) that ovaries were misplaced. Electricity was used and another operation advised by Dr. C.; this she would not consent to. During the summer of 1896 had nervous prostration. In February, 1897, she went into Christian Science and became perfectly well after eleven treatments in three weeks. Her two children had measles at one time; healed them herself by Christian Science in four days; at another time they both had mumps; healed them both in four days. No isolation in either case.

All these cases were chosen by Christian Scientists; no doubt then they are among their "good" cases, and I presume I have not been offered any of their "failures." I have examined all the subjects and rejected none of the cases offered me. Many others refused to state their medical histories, not unjustifiable in my opinion, since in every case I stated my expectation that the histories (without names) would be printed. A number made engagements which they did not keep. The reticence of some seems to be quite without justification. For instance, on November 2d a man arose in an "experience" meeting which I attended and stated that he had been one of a party of about twelve who, while in Central America, contracted yellow fever, he having suffered with the rest. All took medicine but himself; instead he read "Science and Health." Among these men seven died; he recovered completely. Later I called at the church and asked for the name and address of this gentleman, and twice the clerk promised to send me his address. Not having received it I called again about November 21st and asked again. The clerk told me he had not of late seen this elusive Scientist and could not obtain his address.

Another instance: I had been told that a young lady living out of town had been "healed" of consumption. I wrote her mother, who sent me a kind note inviting me to call several evenings later and enclosing a time-table, etc. She said: "I shall be happy to give you any information in my power as Christian Science has been a great blessing in my family." Before the appointed evening I received a note breaking the engagement. Again: At an "experience" meeting which I attended a man arose and declared he had cured a case of locomotor ataxia to such an extent that the patient's two former physicians had been lost in amazement at the change. I learned also that his wife, another "healer," had cured a case of cancer of the tongue. I wrote this gentleman and he sent me an answer kindly inviting me to call at his house. He lived out of town. I went to his house and spent the greater part of an evening trying to prevail upon these two people to show me or to introduce me to these subjects of locomotor ataxia and cancer of the tongue. They utterly refused to do so. Their line of argument was quite of the same sort as that contained in the letter of their better-known "brother in the church" which appears in the first part of this paper. I was not making an investigation in the right way. What I ought

to do was to study "Science and Health" and the other elucidatory works—above all with an obedient spirit—and "the truth" would come to me in time. Or possibly this pair of "healers" had in mind this reasoning, not new in my observation: In the mind of the Christian Scientist the locomotor-ataxia patient was healed, but his "healer" withheld him from inspection by the deceptive senses of those outside the pale of Christian Science, to which senses the patient might appear to stagger about and be as ill or more ill than she ever was before.

Following is a copy of this "healer's" letter:

"MY DEAR DR. HUBER:—I received your letter with Joy, and name next Monday eveng as a time to give you for your enquiry into the workings of Truth as it has come under my notice. Our field is a broad one coverig several towns, and we have not lately had an eveng free for discussin the subject coverig this sublime and stately Science That leads into all Truth even to the solving of the problem of Being. The healing of the Sick is only the primary steps this step however is an important one as its demonstration with proof attests its divine origen even God—Good, its principle source and ultimates in Eternal Life. For the Life is in his Son and Divine Science reveals this son Even our own Christ our spiritual Individuality God being our Father and mother.

"Yrs. in Truth

"——— C. S."

Should not a person of this sort be compelled to pass some kind of a medical examination before being allowed to come near the sick?

Before concluding, the following observation will tend to illustrate the inherent dishonesty of this movement: One of these "healers" complained to me of the disadvantage at which Christian Science is placed in these times. Should one of their patients die the case must become a coroner's case and be subject to his investigation. A Christian-Scientist's certificate of death would not be accepted. Therefore, should they get into any trouble of this sort, they have to seek (and it is declared they sometimes find) an obliging physician who will get them out of their trouble by signing a certificate for them.

It is difficult to treat some aspects of this movement seriously; of others no criticism could, to my mind, be sufficiently condemnatory. Many of the dangerously sick are in the hands of these people. We are, therefore, I think, entitled to absolute frankness from them concerning their methods. This attribute I, for my part, have often found deplorably lacking. There are personal observations in this paper which are intended to illustrate the character of the movement; therefore I consider them justifiable.

Many Christian Scientists are undoubtedly good and worthy people; these demonstrate anew the well-established fact that mankind, generally speaking, displays an extraordinary readiness to be humbugged. Those in authority in Christian Science make it evident that they fully understand and know well how to reap the utmost advantage from this trait in human nature. If these people really have the good of human kind at heart they are certainly the most original truth-holders and truth-offerers that have ever appeared in the world's history.

The chiefest and the one essential attribute of those who have loved and have tried to lift up mankind has been absolute self-abnegation. And the greatest among these He, in whose garb these people are hideously masquerading, was the humblest and the most unselfish of them all. But consider the woman who is at the head of this movement. Besides the facts already stated to illustrate her sordid motives there are these: She has for many years been conducting a "metaphysical college," in which her pupils have paid a regular fee of three-hundred dollars for a two-weeks' course in order that they might, in their turn, reap the pecuniary benefits to be got out of this movement. She has with unspeakable presumption imitated the recorded healings of the Master, but, in a spirit wofully unlike His has exacted enormous fees for the exhibition of her alleged powers. She preaches the brutal doctrine that "no one has any business being poor." She is hedged in by "counsel" and other legal paraphernalia, and through this "counsel" must the outside world communicate with her. Such is the spirit dominating "Christian Science." What a contrast! On the one hand this movement; on the other the personality upon which it trades and of which it makes capital—that of "the pale, staggering Jew with the crown of thorns upon His bleeding head."

THE GARRISONING OF OUR TROPICAL POSSESSIONS.

No. 4.

THE HISTORY OF SPANISH MILITARY OCCUPATION. STATISTICS OF MORBIDITY AND MORTALITY.

BY SENECA EGBERT, M.D.,
OF PHILADELPHIA;
PROFESSOR OF HYGIENE AND DEAN OF THE MEDICAL FACULTY IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

IN preceding articles I have referred to the dangers to which our troops will be exposed, and to the great necessity of employing every possible precaution to guard against them. It will be the purpose of the present article to show that the aforesaid statements are not exaggerated and, at the same time, to show how unable Spain was to cope with the morbific conditions, even though through her former experience she was well acquainted with them. The so-called Ten-Year's War that was be-

gun in October, 1868, by the armed revolt of the Cubans under General Manuel de Cespedes, is said to have cost Spain 100,000 lives, the larger part of which undoubtedly yielded to disease rather than to wounds received in war. But though knowledge of sanitary methods and of the means of combatting disease have greatly increased since the termination of this earlier conflict, and though the duration of the second insurrection, which began in February, 1895, and which has just terminated, was much shorter, conditions were scarcely, if at all, improved in the latter struggle, and Spain's sacrifices were comparatively even greater than before. As may be surmised, it is difficult at the present time to secure exact and reliable statements of the Spanish losses during the past four years, and I would accordingly acknowledge my indebtedness to the "Report of the Inspector-General (Losada) of Spanish Forces in Cuba," dated December 12, 1897, and to a summary of the report of Dr. de Larra Cerezo, Chief of Clinic in the Cuban hospitals of Madero and Alfonso XIII., published in a recent number of the London *Lancet*, from which, unless otherwise noted, the following data have been taken.

Even before the late contest began and in time of peace, Spain found it necessary to keep in Cuba a standing army of 14,000 men, of which a large proportion were constantly being disarmed by the climate. Some died, more were sent home, and others who recovered and became acclimatized were retained in service, but it was found necessary to assign these to garrison duty only, in which there was little fatigue and no exposure.

Then came the uprising early in 1895, and suddenly—within twenty-one months—200,000 soldiers were sent to Cuba, and within one or two months after their arrival one-half of them were invalided. In March, 1895, the only hospitals in Cuba were at Havana, Santiago, Santa Clara, and Puerto Principe, together with nine widely separated local infirmaries, in all of which the medical and sanitary corps of the army had at its disposal only 2500 beds.

To satisfactorily provide hospital accommodations for approximately 100,000 men in but little more than a year and in a foreign country would tax the medical resources of a nation even greater than Spain. With our knowledge, we may feel that better results than those to be related should have been obtained, but we must give credit to our Spanish medical brethren, who were doubtless much hampered and harassed by military and economic exigencies. By January 1, 1898, many new hospitals had been erected, and there were 46,685 beds in them to receive the sick, and of the 600 surgeons engaged between the outbreak of the rebellion and the middle of 1897, at least 50 died in the pursuit of their duty, most of them victims of yellow fever.

Dr. Cerezo says: "The statistics of the Alfonso XIII. Hospital (of Havana) for 1897 showed a great reduction from those of the former years in the death-rate from yellow fever, but an increase in deaths of a general medical nature, probably on account of the lowered health of the army due to the bad climate and the hardships of the campaign. The deaths due to wounds were also comparatively less. The great evil results from the anemic condition of the troops, and though the figures relate to but one hospital, still they may be accepted as typical of all the military medical services of the island."

From March 1, 1895, until April 1, 1897, nearly half a million patients were treated in these hospitals, *viz.*: March to December, 1895, 49,485; deaths, 3200. 1896, 233,714; deaths, 10,610. January to June, 1897, 201,247; deaths (January to March), 3691. In the military hospitals alone the yellow-fever patients numbered 35,250 (of whom 11,347 died), and "many more sick with this disease were treated in civil hospitals, camps, towns, and villages, forts and private houses, and even in sugar refineries."

The following record of the yellow-fever patients treated in hospitals and infirmaries for the respective years shows that in its ravages and results it can be "more fatal than bullets."

Year.	Cases.	Mortality per cent.
1880	1470	37.85
1883	1285	45.34
1885	120	55.
1886	130	26.92
1894	859	32.82
1895	7085	39.46
1896	23,580	30.99
1897 (5 months)	4636	27.20

Other statistics from the same source—Dr. Cerezo's report—are as follows: Number of wounded nursed in hospitals, 1895, 1989; 1896, 7270; 1897 (part), 2643. The total deaths in the army from March, 1895, until May, 1897, were 22,497. [1] During the past year 32,000 Spanish soldiers died in hospitals, and 30,000 were invalided home.

In April, May, and June, 1896, there were 3193 cases of dysentery with 351 deaths, 2903 cases of typhoid fever with 576 deaths, and 2281 cases of tuberculosis with 299 deaths treated in the hospitals, in addition to which there were also 79,552 cases of malarial fever severe enough to need and receive hospital treatment in 1896-97.

It must be remembered that these figures are only partial and fragmentary, for it was most difficult to secure and keep accurate accounts at this time, and, besides, there were many thousand other cases of illness in men too far away to be sent to the hospitals.

Such as they are, however, they serve to indicate the task that our Government has before it. It is true that our troops will be in a presumably friendly rather than a hostile country, that they will have no enemy harassing and attacking them, that they will be comparatively near to their bases of supplies, and that Anglo-Saxon is not synonymous nor comparable with Spanish management of affairs. But no one can deny that the dangers of disease are still rife throughout the whole island of Cuba and that the statistics presented in this and my preceding articles show that only the greatest vigilance and best sanitary

[1] *Lancet*, 5-28, p. 1492, 1898.

management can protect our garrisons from serious disasters. Many will doubtless fear that safety is impossible of attainment and that, if not immediately, as soon as the wet season returns we shall have reports almost, if not quite as depressing and grave as those that came from our men at Santiago last summer. Certainly this would be the result of ignorance, lack of foresight, or of inaction—all inexcusable.

The etiological factors of each of the threatening maladies are sufficiently well known or understood to secure a large measure of prevention, and from all reports received there can be only the most satisfactory results following upon general and well-directed sanitary work throughout the island.

We can analyze the statistics we have at hand, we can be warned and guided by Spain's and our own experience; we can employ the scientific knowledge that we already have and be informed by the advice that Colonel Waring left us, and the results that Dr. Wood has so satisfactorily attained.

Inspector-General Losada of Spain, in his report already referred to, attributes the great death-rate and sick-list in the Spanish Army to three factors, *viz.:* To the fact that the clothing of the troops was not adapted to the tropical climate, to fatigue, and to lack of proper food; and from this the *Lancet* draws the lesson that it is always wise and necessary to have the sinews of war in adequate supply, and to make due allowance for climate, whether tropical or subtropical, which may prove as destructive as the enemy in action.

Indeed, the case is by no means hopeless. If the preceding statements seem to indicate invincible perils we should arouse every one to their importance. The purpose of these articles is to show how some of them, at least, may be conquered. We have already referred to the sanitary conditions formerly prevailing in Jamaica and how they have improved under British management. Statistics are not necessary to substantiate this, but it will be interesting to simply note that in 1897, at the time when the Spanish hospitals in Cuba were full to overflowing and disease was rampant everywhere, the death-rate for Jamaica was but 24.2 per thousand, ranging from 19.4 in Manchester Parish to 29.2 in Kingston Parish, and that on January 31, 1898, the Acting Governor of Jamaica reported the island to be entirely free from yellow fever.

I may also refer to the statements of Professor Guiteras in the *Philadelphia Medical Journal* of last spring that it is possible to prevent the infection of military garrisons with yellow fever and that the chief dangers lie in the communication of the troops with, or the receipt of supplies from, infected places.

He said: "Yellow fever is circumscribed within certain areas and if it is possible to keep troops away from these areas there will be little danger of infection. There are places (in Cuba) where there is no yellow fever. In some places on the coast (as well as in the interior) the disease is not to be found. As a general rule, the more important a place, the greater its commercial activity, the more infected it is. A congregation of people in the interior could not originate yellow fever. Still the disease may be carried to a garrison from an infected town. To guard against this the troops must be placed by themselves in uninfected places, and they must not communicate with infected places. Then, too, no depot of supplies should be placed in an infected port. This is, of course, a desideratum that it may be difficult to obtain for strategic reasons. Ideal conditions are not always possible in a military campaign."

In the *Atlantic Monthly* for December three separate writers, well informed and who have made a special study of the conditions, express their belief that self-government by the present inhabitants of our newly acquired tropical possessions is thoroughly impracticable for many years to come, perhaps forever, and that this country will accordingly have to maintain authority and accept and continue in supreme charge of affairs.

Whether we individually believe in the policy of national expansion or not it is evident that it behooves the Government, if the above views are in any measure correct, to give some thought of permanence to whatsoever sanitary plans or methods it may adopt for the welfare of the army. And perhaps it will be better so, for, if it is probable that the garrisons will have to be maintained for a long time—many years—there will be the greater willingness to provide the necessary funds for all that makes for their comfort, contentment, or health. Barracks, water-supplies, drainage-systems, etc., will all be better planned and better constructed if they are to be for more than temporary use, and other hygienic problems will be the easier of solution.

One caution remains. The large cities of Cuba need immediate and the most thorough sanitary attention. We all rejoice that the recommendations that Colonel Waring was about to make to the Government in relation to the sanitary reclamation of Havana are now available for our consideration. Measures will probably soon be taken to put them in force. Let us hope and urge that in the praiseworthy zeal and eagerness to improve the conditions of the native residents, who are more or less acclimated and accustomed to their unhygienic environment, we do not forget or neglect the interests of our own men who will be far more susceptible to infection and deterioration of health. They should have the first thought and should be made to feel that the dangers of their duty are fully appreciated by the rest of us whom they serve.

MEDICAL PROGRESS.

"Sleeping Sickness."—MANSON (*Brit. Med. Jour.*, December 3, 1898) has had under treatment at the Charing Cross Hospital, London, two negro boys from the Congo Valley, who have had "sleeping sickness" for some months, and were brought to England for treatment. Thus far the disease is known to occur only in negroes and half-breeds, and only in those who are living or have lived in West Africa, between Senegal and Loanda. In this district it attacks different villages in epidemic fashion. All who contract the disease die from

it. It has been known to develop in negroes from this Congo region as much as seven years after they had left the country, but in no instance has it spread to other negroes who were not from the Congo. The chief symptom is a mental vacancy, gradually increasing until the patient has to be roused to be fed, associated with muscular weakness, enlarged lymphatic glands, and usually, pruritus. There may be irregular fever. As the disease progresses the patient becomes bedridden, and muscular spasms and contractions develop, death resulting from them or from diarrhea or bed-sores. The average duration is about nine months, though the fatal termination may be delayed for two or three years. The etiology is not known, but the occurrence in the blood of both of these patients and in one previously received in London of a parasite called filaria perstans suggests that it may produce the symptoms described. The history of sleeping sickness and its occurrence only in a certain district, while it may develop after years in those who have lived in that district, points to the fact that it is due to a germ which must pass one stage of its existence in some plant or animal which grows only in that particular locality.

With commendable zeal Marston procured slides of blood of hundreds of natives of different parts of Africa and other tropical countries. This filaria he found in the blood of those who live in Congoland, and in two other parts of West Africa. In these districts more than fifty per cent. of the specimens of blood obtained from a large number of negroes contained this parasite. It is, therefore, necessary to explain why all the negroes so affected do not have the sleeping sickness. The reason for this, Manson suggests, may be that the parasite is comparatively harmless until it either enters the brain or interferes with its nutrition. In several autopsies there have been found lesions in the pituitary body. No efficacious treatment is known. Both of the patients under treatment were suffering from round worms and ankylostomata when they reached London. They grew a little brighter when their intestines were cleared of these parasites, but the improvement was only temporary, and the real disease has steadily progressed.

Pathogeny of Enteroptosis.—ROSENGART (*Rev. Gen. de Path. Int.*, December 5, 1898) has been brought by the researches which he has made to the opinion that enteroptosis is a returning of the abdominal viscera to something like the positions which they occupied in fetal life. All the causes which depress the diaphragm, as well as all of those which relax the abdominal wall, tend to push down the liver to its fetal position. Thus gastroptosis is found in individuals with curvature of the spine, or long narrow thoraces which have ossified too soon, as well as in those who suffer from emphysema or phthisis. He also blames the corset in women and tight belts in men. With the sinking of the liver the stomach also sinks, especially its pyloric end, and the ascending colon being compressed, exerts its action on the right kidney. Hence, the right kidney is frequently loosened, while the left is seldom affected.

Mucomembranous Enterocolitis.—DE LANGENHAGEN published a monograph on the above subject, of which a review appears in the *Rev. Gen. de Path. Int.* for December 5, 1898. The exudates may be glairy, amorphous, or membranous. The seat of the trouble is the whole extent of the large intestine, rarely the lower end of the ileum. The lesions are always superficial and catarrhal. There are numerous bacteria in the discharges, especially the bacillus coli. There is constipation, alternating with false diarrhea. There may be hemorrhages apart from hemorrhoids of half a pint or a pint. There are sharp pains, and often paroxysms simulating peritonitis. Sometimes a grave condition results, especially in children, marked by vomiting, fever, and occasionally, purpura. Palpation of the abdomen gives a peculiar sensation, due to the atony of the intestinal walls, which the author describes as "cloth-bowel" (*l'intestin-chiffon*). Sometimes the atony gives place to spasm, and there are besides modifications of caliber, so that one may sometimes observe alternating dilatations and contractions. Palpation of the cecum often provokes gurgling. The liver is ordinarily retracted. Nephroptosis on the right side is the rule. Ptyalism and superficial inflammation of the mucous membrane of the mouth, gastric dyspepsia, and dilatation of the stomach are also common symptoms.

Among the complications frequently observed were acholia with discoloration of the feces, pseudoangina, asthma, and vasomotor troubles. Above all should be mentioned intestinal lithiasis, which is always accompanied by mucomembranous enteritis. There is no connection between this trouble and appendicitis. In the 130 cases studied there was no instance of appendicitis. Neurasthenia and hysteria were common. The evolution of the disease comprises two stages: enterocolitis pure, and the same associated with enteroptosis. It is of a neuro-arthritic nature. The minimum duration of treatment is three years, and cases may hold on from five to twenty years. Children are often attacked, and women are more susceptible to the disease than men. After giving details of the diet, the writer speaks of the best means to combat the constipation (castor-oil in small doses and cascara) and of calming pain (hot applications), and describes the technic of enteroclysis, which he has found to be most serviceable.

Bactericidal Action in the Mouth.—HUGENSCHMIDT (*Centralbl. f. inn. Med.*, December 10, 1898) tested the action of human saliva after passing it through a Chamberland filter, in order to free it from all germs, and found that it then had no bactericidal power worth mentioning. The saliva has a chemotactic influence on the leucocytes which leave the numerous lymph-vessels of the mucous membrane of the mouth and throat in consequence of this influence and mix in the saliva. Their phagocytic power makes a bactericidal agent of the saliva. Perhaps even a more important protection against the entrance of pathogenic germs through the mouth into the system is found in the great numbers of saphrophytes in the mouth, which find in the saliva a better medium for their growth than do the pyogenic organisms, and which, therefore, outgrow the latter.

An Emulsion of Mixed Fats.—RUSSELL (*Post-Graduate*, December, 1898) tested emulsions of eleven different fats in order to ascertain whether they would increase the weight of a patient taking them, and whether they would allay cough. Some of them he found to be deficient in both particulars, some of them to be variable, in which class was cod-liver oil, and some of them constantly fulfilled both requirements. The best ones were beef-fat, olive, cocoanut, and peanut oil. These were tried further, and it was found that each lost its effect after a little, so that by alternating from one to the other more good could be derived. So in order to give the system the advantage of a variety of these four fats, they were mixed together in an emulsion to which a little clove oil was added. This emulsion he considers far superior to an emulsion of cod-liver oil, and has found by trial that it is well borne in febrile conditions.

THERAPEUTIC NOTES

Treatment of Erysipelas by Heat.—RABINOWITSCH (*Rev. de Therapeut.*, November 15, 1898) treats patients who have erysipelas in the following manner: The affected portions of the skin are covered with moist gauze over which is passed back and forth a lighted cotton swab soaked in alcohol until the pain is beyond endurance. This "cooking" of the inflamed skin is repeated three times in the twenty-four hours. The result is an intense local inflammation, sometimes with the formation of blisters, especially so if there were already a few blisters before the treatment was commenced. If the extent of the erysipelatous process is very great, the author contents himself with the heating of the marginal regions. The results were very good indeed. In many instances the pathologic process was aborted in twenty-four hours. In general, however, seven days were required to complete the cure. More than 200 patients have been treated in this manner by Rabinowitsch.

Combined Heat and Cold as a Hydrotherapeutic Measure.—BERGMANN (*Bull. Gen. de Therap.*, October 30, 1898) applies heat and cold in the treatment of subacute and chronic abdominal affections in the following manner: The patient takes a warm bath lasting fifteen minutes, the temperature being gradually raised. He is then lifted from the bath without drying, and placed in a bed on two cold wet folded sheets, which lie in the form of a T. The arms of the T are brought up about the chest and abdomen, from the epigastric to the inguinal regions, and the vertical portion of the T is brought up between the thighs, so as to cover the perineum and genital organs. Outside of this wet pack there is a blanket in which the patient is then rolled, and left during the night. The first chilly sensations are followed by an agreeable warmth, and a mild vapor bath, so to speak, exerts a calming and hypnotic action, which will often succeed in inducing sleep, although chloral, trional and similar remedies have failed. In the morning the patient jumps into a cold bath, where he remains for five seconds, and then returns to bed, not rising until he is thoroughly dried and warmed. The author has obtained brilliant results with this treatment, in cases of chronic gastritis, hemorrhoids, intestinal atony, and biliary calculus.

Massage for Post-Operative Ileus.—HABERLIN (*Centralbl. f. Gynäk.*, October 22, 1898) reports a case of ileus following a ventrofixation, in which the passage of gas and fecal matter followed so immediately upon the massage of the abdomen, as to leave no doubt of the relation between the two movements. The uterus and adnexa were found at operation to be fixed in Douglas' pouch by adhesions. These were separated. After the operation a saline was given. Six hours later, without vomiting there were attacks of colic which persisted, and the patient had the feeling that there was some obstruction in the lower pelvis. Large enemata, produced some fecal matter but no gas passed the anus and the abdomen became more and more distended. With the finger in the rectum he could feel a coil of intestine immensely distended, and in spite of the pain caused by its manipulation, the coil was massed between this finger, and the hand placed on the external abdominal wall. The withdrawal of the finger was followed in a short time by the passage of quantities of gas and many fluid stools. The massage was made on the third day after operation. On the next day everything was vomited, but after that the patient made an uneventful recovery. Haberlin thinks that massage ought to be tried in similar cases of ileus after operation or in strangulated hernia, and that the danger of hemorrhage, increase of pain or of rupture of the intestine is not a serious one.

Good Effects of Arsenic Iodid in Lymphatic and Scrofulous Children.—SAINT PHILIPPE (*Rev. de Therapeut.*, December 1, 1898) recommends the use of iodid of arsenic in the treatment of scrofula. Iodin is certainly the best remedy for the treatment of scrofulous conditions, but the forms in which it is administered are generally unreliable or irritating, as are the iodid of iron, or the tincture of the iodid, or the iodid of potash. Iodid of arsenic prescribed in a certain manner will produce remarkable results in the presence of such symptoms as scrofulous dermatitis, ophthalmia, coryza, nasopharyngeal catarrh persisting after the ablation of adenoids, recurrent bronchitis, painless enteritis, fetid diarrhea, etc. The author employs a one-per-cent. watery solution of the anhydrous arsenic iodid, *prepared cold*. It is taken either in a spoonful of water or sweetened milk before each meal, or in a glass of water which is drunk during the meal. In very young infants it is well to begin with a single drop morning and night, and gradually to increase this amount, until 20 drops are taken per day, unless signs of intolerance are sooner observed. Even in older children it is not usually good to give more than this amount. The evidences of too rapid an increase in the drug are diarrhea, anorexia, excitation or insomnia, all of which disappear at once if the administration is suspended. The author increases the amount gradually, then keeps it at a maximum for several days, and then gradually decreases it until the minimum dose is given, and then after some days of rest, he repeats this increase and decrease if the condition of the patient requires it.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the Medical News will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SATURDAY, FEBRUARY 11, 1899.

MILK AND TUBERCULOSIS.

Both Dr. Brush and Dr. Pryor at the recent meeting of the State Medical Society in discussing the question of the relation of the State to the prevention of tuberculosis insisted on the necessity for the more careful inspection of cattle and the destruction of animals known to be infected. This is a matter that cannot be too often forced upon the public attention. Tuberculosis, because its usual manifestation is in the lungs, is considered to be, almost without exception, an air-borne disease. Methods of inspection that look to the prevention of other sources of the disease are, therefore, especially if they involve a certain amount of expense, considered to be of such secondary importance that they may be neglected without serious danger.

This is a very short-sighted policy. It is by no means proved that contagion, even though its first manifestations occur in the lungs, has always taken place through the respiratory tract. It is to be remembered that the lung capillaries constitute in a certain way a kind of sieve between the venous and arterial circulatory system and that though the infecting agent may have entered through the digestive system, it is not impossible that its first manifest lesion may be in the lungs. But apart from this consideration, which may be too often overlooked, tuberculosis of the digestive tract itself is by no means a factor that may be neglected with impunity.

The Parliamentary commission for the investigation of the question of tuberculosis in England called attention to the fact that while there had been a very large reduction in the mortality from pulmonary consumption in these last twenty years a corresponding reduction in the death-rate from other forms of tuberculosis in which the point of entrance of the tubercle bacilli might be reasonably supposed to be the digestive tract had not taken place. In fact the statistics of tubercular peritonitis in children had lagged so far behind the generally improved statistics of other forms as to be very striking. The commission did not hesitate to attribute infection in these cases to the consumption of tuberculous milk.

Of the greatest interest then in this matter is some work done under the direction of that talented pathologist whose early death has deprived Anglo-Saxon medicine of a most promising and successful worker, the late Professor Kanthack, Professor of Pathology at the University of Cambridge, England. The report appears in the *Medical Press and Circular* (London) for January 18, 1899. Dr. Sladen, working under Professor Kanthack's direction, examined the milk that was being supplied by some sixteen dairies to ten of the colleges of Cambridge. Most careful precautions were taken that the milk should not become contaminated by any vessels it was placed in after leaving the milkman's hands. More than one-half of the sixteen dairies were supplying milk that contained tubercle bacilli in sufficient quantity to cause tuberculosis in guinea-pigs, when injected into them. Though the results were negative for the other dairies it by no means proves them free from tubercle bacilli, for the number of examinations made, while perfectly clear as to the positive results they furnish, were naturally too few to justify a declaration of innocuousness of the products of the dairies even with the negative results.

Attention is called to the fact of how great a source of danger such milk must be for (1) hand-fed infants, (2) young children, (3) delicate people, (4) all people suffering from acute diseases. In most of these cases a milk diet is often considered necessary.

In some it is the sole diet allowed. Many of these patients do not drink boiled milk so that frequently when resistive vitality is especially lowered they are given to drink what are virtually cultures of virulent tubercle bacilli. The need for regulation of the milk-supply of large cities with special reference to the existence in it of tubercle bacilli seems to be made perfectly clear by these late investigations. Yet we understand that the work of the New York State Commission in the matter is at a standstill for the want of funds. We can only re-echo the warning rung out so clearly by Drs. Brush and Pryor, that economy in the regulation of tuberculosis is fearfully expensive economy, expensive in actual money and, above all, expensive in the lives and health of citizens.

THE TREATMENT OF FRACTURE OF THE PATELLA.

RECENT reports from England show that the Prince of Wales' recovery from his fracture of the patella is proceeding very satisfactorily. There is still a slight halt in his gait, but this is said to be due to the fact that as a precaution against accident the Prince is still required by his surgical advisers to wear a bandage at the knee. The case has reawakened general interest as to the question of operative or non-operative intervention for fractures of the patella.

At the time of the accident to the Prince our New York contemporary, the *Medical Record*, said: "As he has the misfortune to be an exalted personage his surgeons will probably fear to treat his injury radically, with the result that the poor man will be lame for life." Malcolm Morris, the editor of the *Practitioner* (London) commended to his "able but impulsive contemporary the example of Mark Antony, who only spoke of that which he did know," and said, with more force than grace, that the spectacle of Lord Lister, Sir William Mac Cormac, and Sir Thomas Smith treated to a lecture on surgery by the *Medical Record*, reminded one irresistibly of the story of Hannibal favored by the old philosopher with his views on the art of war. Hannibal on that memorable occasion, with blunt military impatience, it is said, interrupted the interview with the order to remove the fool.

The case certainly demonstrates that there are eminent surgical authorities who still believe in simple, non-operative, as opposed to what the *Record* calls radical, treatment of fractures of the patella. The employment of the older, simpler method in this case was certainly not due to over conservatism on the part of the attending surgeons, induced by the fact that their patient was so exalted a personage, or because they themselves had reached years where conservatism ceases to be a virtue, and becomes merely the old man's protest against things that are new because they are new. It is rather the expression of the feeling, yet common enough in the profession despite the protests of advanced "radical" operators, that the older mechanical methods will in the great majority of instances give excellent functional results, and that it is only in exceptional cases in which some complication exists, or in which the patient's subsequent livelihood depends especially on the perfect use of the extensors of the thigh that surgical intervention will be called for. Some one has well said that though the Prince's great occupation in life is to be the ascent of a throne, the manner of that ascent has a quite indifferent value as regards his compensation in after life compared to what it would be did he as a painter, for example, have to ascend a ladder for a living. We are pleased to note the thoroughly conservative view that Professor Stimson takes of the matter in the advance sheets of his new book, shortly to appear from the press of Lea Brothers & Co.:

> The points to be considered in choosing between these two main methods (operative and non-operative) for fracture of the patella are that a long experience has shown that non-operative methods furnish in the great majority of cases in which they are properly used a result which is functionally satisfactory even if the union of the fragments is not close, that most of the failures are apparently due to unfitness of the method chosen or its faulty use, that only in a small proportion of cases are the conditions such as to make a bad result inevitable without resort to operative methods, and that most of the later causes of limitation of function are equally active after either operative or non-operative treatment.

Yet this is the opinion of a man of large experience who has all the facilities at hand for thoroughly aseptic operation, and who has besides for special reasons operated successfully in some seventy cases of fracture of the patella.

THE SALOON AND THE CRAVING FOR STIMULANTS.

A GOOD deal of discussion has been aroused in New York by the supposed expression of a prominent member of the Episcopacy of the city as to "the saloon being the poor-man's club." It eventually appears that the expression was not used in the slightest degree by the reverend gentleman in the sense in which his critics condemn it so severely; but that has not yet put an end to the discussion. The odium theologicum still prompts the throwing of some barbed shafts of sarcasm, which to a rank outsider seem far more calculated to rankle in an opponent's breast than turn him gently from the error of his ways, if he is in error.

Meantime, the question itself of the place of the saloon (rum-shop) in modern life rather than of the manner of the present discussion is of interest to medical men. There is a large class of people in every community who do not permit their lights to be hidden under a bushel, as a rule, who think that the saloon, with all its attendant evils, can be legislated out of existence. For them the whole problem is one of law-making. They do not seem to realize all that human nature stands for in the matter. Long ago Horace said, "*Naturam expellas furcâ, tamen usque recurret,*" "You may pitch human nature out with a fork, but she will come back again, never fear!"

Some of the facts in relation to the human race and alcohol are interesting in this connection. There has never been found, we believe, an important tribe of human beings, no matter how degraded they might be, who have not had a method of making a stimulating liquor containing a certain amount of alcohol. It has under most varying circumstances been made from the most various materials. But starch is an essential element in vegetable tissues, and has always formed an important item in human diet. It is easily converted into sugar, and a sugar solution exposed almost any place in the world becomes contaminated with the yeast-plant from the air, fermentation ensues, and alcohol is formed. Nature would seem to have conspired with the forces that make for evil, if we are to believe our total-abstinence friends, in thus making the yeast plant and starch and sugar so universal. As we have said, man, no matter how low in the intellectual scale, has always found out how to make for himself the products that Nature put so temptingly near him.

Now, we do not pretend that this in any sense justifies the taking of alcoholic beverages to excess, but we humbly submit that it seems to point out the fact that no mere legislation at this stage in the world's history is going to do away with the consumption of alcoholic stimulants. The craving for stimulants on the part of the hard-working man is too great to ever allow us to hope for that. We realize the evil that the modern liquor traffic brings with it. As doctors we know the awful procession of physical evils the abuse of alcohol brings in its train, but we know that Nature cannot be legislated out of the problem. Removed with a fork she will come back. Directly opposed she will override every obstacle, but she may be guided into paths where the inclinations she instils even when abused may do as little harm as possible.

With the good bishop, who, if he spoke of "the saloon as the poor-man's club," did so only to impress the fact that something must be found to replace it or the legislation of it out of existence will be unavailing, we heartily agree. When the temperance people can invite the workingman to places that are as cosy and as comfortable as the saloon in which to spend certain hours that would otherwise drag on his hands, and when they will have enabled him to find there in answer to his natural craving for stimulants the milder ones, tea and coffee, that cheer but do not inebriate, then they will have done something to solve the saloon problem.

ECHOES AND NEWS.

Health of Troops in Cuba.—On January 29th it was reported that during three days there had been no deaths among our troops in Cuba. This is considered a remarkable showing.

The American Gastro-Enterological Association.—The next meeting of this Association will be held at Washington, D. C., May 1 and 2, 1899. Dr. Charles D. Aaron of Detroit is secretary.

The New Mt. Sinai Hospital, New York.—One of the features of the new structure will be a large detached building, fronting on Fifth avenue, which will be devoted exclusively to pay patients. The site cost $387,000, and the buildings will cost about $600,000 more.

Christian Science in Chicago.—Christian Scientists in Chicago have subscribed $20,000 for two new temples, one for

the North Side and the other for the West Side congregations. Besides these, a third temple, situated in Drexel Boulevard, was dedicated a year ago.

The New York Medico-Legal Society.—This Society held its annual meeting and dinner on January 30th. It was resolved that a committee be appointed to memorialize Queen Victoria, through the Home Secretary of Great Britain, urging the release of Mrs. Florence E. Maybrick.

The Brooklyn Branch of the State Medical Association.—The fifteenth annual meeting of the Fifth District Branch of the New York State Medical Association will be held in Brooklyn on Tuesday, May 23, 1899. Dr. Joseph D. Bryant is president, and Dr. E. H. Squibb, secretary.

The Ninth International Congress of Ophthalmologists will be held at Utrecht, Holland, August 14 to 18, 1899. The communications and discussions will be presented in either French, English, or German. Dr. D. Argyle Robertson, president of the Eighth Congress, is chairman of the Committee on Organization.

Dr. Wurdemann Becomes Editor of the "Annals of Ophthalmology."—Dr. H. V. Würdemann of Milwaukee, who has been associate editor of the *Annals of Ophthalmology*, has accepted the position of editor-in-chief, vice Dr. Casey A. Wood of Chicago resigned. Dr. Wood will retain an interest in the publication, and will have charge of the department of Italian literature.

The Philadelphia Medical Journal versus the Eyes of Its Readers.—It is to be regretted that our otherwise attractive contemporary should have impaired its usefulness by a marked degeneration in its recent issue as to the quality of the paper and printing. Due regard for the overwrought eyes of many of its readers dictates a return to its previous much more acceptable physical condition.

Sanitation in Havana.—On February 3d General Ludlow, Governor of the City of Havana, telegraphed to Secretary Alger as follows: "Death-rate for January reduced forty per cent. below last year. Causes, sanitation of streets and houses, cleansing local points of infection, vigilance in watching and isolating infectious cases, medicines, and supplies to sick and food to starving."

Connecticut School-Boys Physically Deficient.—Dr. Jay W. Seaver, the well-known Yale authority on anthropometry, and director of the Yale gymnasium, declares that of the 2500 students at Yale the poorest physical specimens come from New Haven. There are more than 300 New Haven boys in the University. Dr. Seaver insists that the physical training in Connecticut schools is inadequate.

Boston's Public Baths.—Mayor Quincy of Boston says that that city was the first in America to establish public baths, the oldest bath having been opened thirty-three years ago. Boston has twenty-three summer baths, and last summer 1,900,000 baths were taken. The baths are free for children, and in all but one adults pay five cents for a bath and one cent for a towel. The cost of maintenance was $38,000.

The Seventh International Congress against the Abuse of Alcoholic Liquors will be held at Paris, April 4 to 9, 1899. The preliminary program gives promise of a discussion of nearly every aspect of alcoholic injury. The president of the Congress is Dr. Le Grain. Short papers on any phase of the subject are earnestly solicited from the American workers in this field. Dr. T. D. Crothers of Hartford, Conn., is the American chairman of the organization.

Influenza in Berlin.—The report came from St. Petersburg recently that influenza was so extremely prevalent among the government officials that public business was seriously interrupted. A similar condition is prevalent now at Berlin. Many of the public officials are suffering from the epidemic, including Baron Von Bülow. At the last court ball one-half of the invited guests were prevented from attending owing to the fact that they were suffering from influenza.

Smallpox in Cuba, Puerto Rico, and the Philippines.—One hundred and sixty-one cases have been reported in the Province of Havana; compulsory vaccination has been ordered. There are at Ponce 150 cases of smallpox under treatment. It has been ordered that all the inhabitants be vaccinated. Among our troops in the Philippines there were from January 8th to January 27th, nineteen deaths, fourteen of which were caused by smallpox. It is believed that the disease will be promptly checked, and no epidemic is feared.

Antivaccination Movement.—General Phelps, President of the Antivaccination League, has given notice that an International Antivaccination Congress, at which it is intended American delegates shall be present, will be held at Berlin in June of this year. The German League is petitioning the Reichstag for the abolition of compulsory vaccination. William Tebb has completed a two-months' tour of the United States; he has been conferring with the leaders of the movement in America, where there is to be a renewed crusade.

Obituary.—Dr. Alvin C. Henderson, Coroner's Physician of Brooklyn, died February 7, 1899, in the Long Island College Hospital. Some time ago some one stepped on the doctor's foot and crushed his toes and gangrene set in. His leg was amputated, but it failed to save his life. Dr. Henderson was born at Cadiz, Ohio, fifty years ago. He was graduated from the University of Michigan, and in 1872 came to Brooklyn. He took a course of study in the Long Island Medical College, and after graduating from there began the practice of medicine in the Eastern District of Brooklyn. He was a member of the Kings County Medical Society and a number of other organizations.

New York State Factory Inspector's Report.—There are nearly 700,000 persons employed in the manufactories of the State of New York. Of this number 472,784 are males and 208,145 females. There are 21,977 boys under eighteen years of age, and 6000 under sixteen years of age employed. The number of females under twenty-one years is 65,045, and under sixteen years 7025. The

number of children employed who did not have the certificate required by law is 810. The inspector finds that there are no abuses of the child-labor law existing, and that there has been a marked falling off in the number of illiterate children found at work. There are no violations of the law governing the hours of labor.

The Baptist Hospital of St. Louis Reorganized.—For the purpose of relieving this hospital from the odium cast upon it by a letter sent out in November and December last offering to physicians sending patients to the hospital one-third of the fees received from them, at a recent meeting of the medical board it was unanimously resolved that this letter was ill-advised, that no more be sent out, and that the letters are no longer effective. It was further resolved that the hospital should be free from prejudicial alliances and impartial in its relations to colleges, religions, politics, or individuals. The medical staff consists of Drs. Bransford Lewis, John Young Brown, John A. J. James, C. C. Morris, Robert Barclay, J. W. Williamson, and John C. Morfit.

Health of Troops at Manila. — On February 2d General Otis reported as follows: Death among troops in Philippines since arrival to February 1st, seven months, 220, of which 41 were due to wounds and accidents. Of the remaining 179, 65 died of typhoid, 43 of smallpox, 22 of dysentery, 8 of malarial fever. The remaining deaths were due to many various diseases. Smallpox causes apprehension. The entire command has been vaccinated several times. Twelve physicians have been engaged several weeks in vaccinating natives. The more sickly season is during the hot months—March, April, May—when fevers, smallpox, and dysentery, are more prevalent. Nine per cent. of the command are now reported sick. A great majority of the cases are slight ailments.

The Increase in the Personnel of the Government Medical Services.—In view of the contemplated increase by the number of 400 in the medical service of the Army, and the proportionate enlargement in the medical corps of the Navy and Marine Hospital Services, the Medico-Chirurgical College of Philadelphia announces the inauguration of a special quiz course for the preparation of candidates therefor, commencing February 1st and continuing for four months. The regulations of the Army require that candidates be between twenty-one and twenty-nine years of age, which limit is extended to thirty years in the services of the Navy and Marine Hospital Services. The qualifications for acceptance are somewhat rigid, and as a rule special preparation is required to pass the examinations, but the positions offered are both honorable and remunerative, and doubtless will be eagerly sought.

Commended to Schenk & Co.—We clip the following from "Humors of Clerical Life" in the *Eclectic* and *Cornhill Magazines*. We cannot say how far the prophylactic was effective in this particular case, but it has as much reasonableness as many another panacea in this line for and against: "A clergyman, walking on the outskirts of his parish one day, found one of his parishoners whitewashing his cottage. Pleased at this novel manifestation of the virtue that is next to godliness, he complimented the man on his desire for neatness. With a mysterious air the worker descended from the ladder, and approaching the fence, said: 'That's not exactly the reason why I'm a doin' of this 'ere job, your Worship. The last two couples as lived 'ere 'ad twins, so I says to my missus: 'I'll take and whitewash the place so as there mayn't be no infection. You see, sir, as how we've got ten of 'em already.'" We commend the whitewashing expedient to enthusiastic experimenters who would like to rule Nature their way.

Care of Inebriates in Germany in 1900.—A new system called "the curator system" for the control of inebriates of Germany has been devised. With the beginning of 1900 there will go into effect a truly remarkable law—a law which places every habitual drunkard under an interdict involving complete submission to the will of a duly appointed "curator." This person will be empowered to put the person whom he regards as a dipsomaniac anywhere he pleases, there to undergo treatment for the malady as long as the "curator" pleases. And a new law formulates a fine, broad definition in telling what an habitual drunkard is. It says that the term includes everybody "who in consequence of inebriety, cannot provide for his affairs, or endangers the safety of others." This measures was first advocated in Germany thirty-five years ago, but hitherto its enactment has been prevented by influences not difficult to understand. How the regulation will work remains to be seen. That it may effect good results is obvious, and equally evident is the possibility that it may lead to tyranny such as would be utterly unendurable—anywhere out of Prussia.

Extracts from "Science and Health." — The book "Science and Health," or the Christian Scientist's guide to health and happiness, is a feast in which all the courses are *bonnes bouches*. The following are extracts taken at random: "The divine mind never called matter medicine." (How did Mrs. Eddy find this out?) "The human mind uses one error as a medicine for another. It seeks, on the same principle, to appease malice with revenge, and to quiet pain with opium." (Admirable logic.) "When the science of being is understood, every man will be his own physician." (He who treats himself, etc.) "The ancient Christians were healers. Why has this element of Christianity been lost? Because our systems of religion are governed more or less by one system of medicine." The author's "experiments in homeopathy had made her skeptical as to material curative methods." "You say a boil is painful, but that is impossible, for matter without mind is not painful." "We weep because others weep, we yawn because others yawn, and we have smallpox because others have it; but mortal mind, not matter, contains and carries on the infection. When this mental contagion is understood we shall be more careful of our company," etc.

The Latest Sham Diploma.—The latest sham diploma that has come to light in England, according to the *Medical Press and Circular* of London, is one exhibited by a

Yorkshire chemist. He announces himself as a Doctor of Refraction, duly examined and graduated (*in absentia*) by the Philadelphia Optical College. He has documents from his *alma mater in distans* making known "by these presents to all whom it may concern, that he has passed a most satisfactory examination in the theory and practice of refraction, and is, therefore, entitled to the highest honors that the college can bestow," "which is not saying much" adds our English contemporary.

Really, we had thought that our neighbors of Philadelphia were more careful of the ethical economy of their medical educational household than this. We supposed the days of Buchanan were gone forever. Least of all would we have expected a diploma-selling institution to spring up in the ophthalmological line since our lusty young contemporary of Philadelphia had shown frequent signs of caring especially for abuses in this branch of the healing art. This is a matter that deserves looking into. Philadelphia's fair name in medical education has become of late years once more a precious treasure to her and her professional progeny. Let it not be smirched again by the diploma traffic!

The Centenary of Nitrous Oxid as an Anesthetic.—A correspondent of the *Medical Press and Circular* of London recalls the fact that this year is the centenary of the discovery of the anesthetic properties of nitrous oxid gas. The discovery was made in the laboratory of the Hotwells Hospital, Clifton, Bristol. This hospital had been erected by Dr. Thomas Beddoes, with the pecuniary aid of Mr. Edgeworth (the father of Maria Edgeworth, the novelist), and of Mr. Wedgewood, the well-known pottery man of those days, and was intended especially for testing the therapeutic value of "factitious airs," the name used at the time for gases artificially produced in the laboratory. It was probably the last week in November, 1799, that Mr. Humphrey Davy, as we learn from a letter to Mr. Davies Gilbert, made his celebrated statement: "As nitrous oxid in its extensive operation appears capable of destroying physical pain, it may probably be used with advantage during surgical operations." Wordsworth, Southey, Coleridge, the younger Priestly, James and Gregory Watt, Wedgewood, Count Rumford, and many other individuals distinguished for literary ability, scientific attainments, and practical talents watched over the birth of modern anesthetics, and had seen the effects of the gas, yet of all of these Davy alone suggested the practical application of the discovery. One of the first to inhale it was Anna Edgeworth, the sister of the novelist, and the wife of Dr. Beddoes, the director of the hospital.

For Pediculosis Pubis.—To avoid the eczema which may result from the use of mercurial ointment, a calomel ointment, 1 to 20, is recommended, or the following lotion:

℞	Hydrargyri chlor. corros. . .	parts 1
	Spiritus	parts 100
	Aq. dest.	parts 400.

The ova can be killed by applications of hot vinegar, somewhat diluted, and scraped off with a metal comb.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

ANTIVACCINATION IN PHILADELPHIA — TYPHOID FEVER AS IT APPEARED AMONG THE SOLDIERS—THIRTIETH ANNUAL MEETING OF JEFFERSON MEDICAL COLLEGE ALUMNI—MEDICO-LEGAL SOCIETY—GERMAN HOSPITAL APPOINTMENTS — PERSONAL NOTES—HEALTH STATISTICS.

PHILADELPHIA, February 7, 1899.

THE antivaccinationists in Philadelphia are to have a chance to show how much ignorance they are possessed of for Charles J. Field has filed a petition in court to compel the principal of a grammar-school to admit his eight-year-old child. The child was refused admittance because she had not been vaccinated, and the petitioner says the refusal was in violation of his constitutional rights and that the Act of Assembly under which the respondent acted is unconstitutional and void, and further, he attacked vaccination *per se*. The case was argued before Judge Sulzberger on Saturday last, and he decided the teacher had complied with the law. The plaintiff's lawyer then asked for an opinion as to the validity of an Act which gives a school principal power to refuse a child admission to a school "unless it had been inoculated with that filthy and loathsome disease known as smallpox." The plaintiff contended further that the medical authorities of the world have declared vaccination to be no safeguard against smallpox, but as he could not quote an authority and failed to show any reason why the law was unconstitutional Judge Sulzberger postponed the case until next Saturday to enable the plaintiff to secure affidavits in support of his position. The present time would seem opportune for killing this antivaccination movement, for Philadelphia has enough to do with her typhoid-fever epidemic without looking for more trouble.

At a meeting of the College of Physicians, held Wednesday evening, February 1st, typhoid fever as it was seen in the soldier-patients at the city hospitals last summer was discussed. Dr. Tyson reported the cases of those patients who were treated at the University Hospital, Dr. J. C. Wilson those at the German, Dr. Meigs those at the Pennsylvania, Dr. B. Franklin Stahl those at the Presbyterian, and Dr. J. M. Anders those treated at the Medico-Chirurgical. The question was then discussed by Drs. H. A. Hare, J. M. Da Costa, R. G. Curtin, and S. Solis Cohen. Among the interesting points brought out was the uniformly low rate of mortality (about five per cent.), the rarity of accompanying malaria, gangrene of the skin, which occurred in some cases at the Presbyterian Hospital (reported in a previous letter to the MEDICAL NEWS), and, lastly, the divergent views as to the value of the Widal reaction.

No hospital showed a much higher rate of mortality than five per cent., though, curiously enough, of four wards at the Pennsylvania Hospital, two in which cold sponging was employed showed a mortality less than half as high as the two in which systematic bathing was employed, both sets of cases being nearly equal in num-

ber. Few cases were reported as having been accompanied by malaria, and in those cases in which malarial plasmodia were found it was the general opinion that the malarial toxin was apparently overwhelmed for the time being by the typhoid toxin, later on evidencing its presence by slow convalescence and irregular chills. The Widal reaction seemed fairly accurate in the majority of cases, though in one particular instance five cases of undoubted typhoid fever from a clinical standpoint gave negative results to two different laboratories working independently of each other.

The thirtieth annual meeting of the Alumni Association of Jefferson Medical College was held Saturday evening, February 4th. The present epidemic of influenza was discussed, papers on this subject being read by several members, after which the Association was entertained by Dr. Edward P. Davis at a supper which was served in the Therapeutic Laboratory.

The annual election of the Medico-Legal Society was held last week resulting as follows: President, Dr. E. B. Wheeler; vice-presidents, Dr. A. M. Eaton and Louis H. Adler; treasurer, Dr. G. M. D. Peltz; secretary, Dr. C. H. Clewell, and librarian, Dr. J. I. Nash.

The Board of Trustees of the German Hospital held its annual meeting last week and an election for members of the hospital staff was held. No changes of any importance were made, the old staff being retained with the addition of Dr. Charles J. Judson as a member of the medical staff, Dr. R. F. Gerlach as a member of the surgical staff, and Drs. Jesse Allen, Clarence W. Wille, John F. Sinclair, A. A. Uhle, E. K. Moore, W. J. W. Peters, and Walter Curry as residents.

Effingham B. Morris has been succeeded by Archibald R. Montgomery as a member of the Board of Managers of the Pennsylvania Hospital. Dr. Henry M. Fisher, pathologist and curator of the hospital has resigned and Dr. Henry W. Cattell has been elected Director of the Ayer Chemical Laboratory of the Pennsylvania Hospital.

Mayor Warwick has appointed Dr. Joseph S. Neff a member of the Board of Charities and Correction and Governor Stone has chosen Dr. John V. Shoemaker for Surgeon-General of the State in place of Colonel Louis W. Read, whose time has expired.

The total number of deaths occurring in Philadelphia for the week ending February 4th, as reported at the health office, was 518, of which number 128 occurred in children under five years of age. The total number of new cases of contagious diseases was 471, reported as follows: diphtheria, 77 cases with 16 deaths; scarlet fever, 33 cases with no deaths; typhoid fever, 361 cases with 38 deaths.

Obituary.—The medical staff of the Demilt Dispensary of New York at a meeting held February 1st, adopted resolutions of respect, expressive of their personal friendship for their late colleague Dr. Judson C. Smith, and their sense of loss sustained by his death as well as sympathy for the family.

OUR LONDON LETTER.

[From Our Special Correspondent.]

THE CRUSADE AGAINST CONSUMPTION—THE CONSCIENCE CLAUSE IN THE VACCINATION ACT—"DR. THERNE" ENDORSED BY THE EXECUTIVE COUNCIL OF THE JENNER ASSOCIATION—DEATH OF SIR JAMES MONAT, K.C.B.—A NEW ALLY FOR THE PROHIBITIONISTS—A REMARKABLE ANOMALY OF THE LUNGS.

LONDON, January 28, 1899.

THE crusade against consumption is spreading with great rapidity here. The English public was slow in awakening, but now that it has done so it bids fair, as usual, to make up for lost time. A constant fusilade of articles, news items, and notes upon tuberculosis and its treatment is being kept up by the entire press from the *Spectator*, the *Saturday Review*, and the *Contemporary* to the *Daily Telegraph* and the *Star*. The reports of the German public meeting, attended by the Empress herself, and containing a statement of the excellent work done in the twenty sanatoria already established in Germany, have been published far and wide, and American sanatoria are held up as models of what ought to be done. During the past week no less than eight different municipal councils as widely separated as Dundee, Hull, Manchester, Darlington, and Lambeth (London) have brought up the question of establishing sanatoria for action. It is highly probable that a conference of municipalities to devise plans for uniform and united action in this direction will be called shortly. Edinburgh is fanning the flame by presenting the excellent results obtained in her special hospital established some four years ago, largely under the leadership of Sir Grainger Stewart. During this time 297 in-patients and 6996 out-patients have been treated, with a gratifying percentage of cures. If the open-air treatment has given such excellent results in the hyperborean climate of "Auld Reekie" it will certainly "go" anywhere.

The Liverpool Hospital for Consumption has just received the generous donation of $75,000, one-half from Lady Sarah Willox, and the other from Mr. J. Hartley, to build a similar sanatorium upon a plot of ground already secured, among the beautiful hills of Cheshire, within easy journey of the city.

There can be no question that the notorious "Conscience Clause" is filling a "long-felt want." The *Pall Mall Gazette* has been tabulating the records, and presents thoughtful Englishmen, as food for reflection in the new year, with the appalling fact that no less than 275,000 children have already been "exempted" during the four months of the operation of the act. At this rate there will be plenty of material for a good, old-fashioned, Sixteenth-Century epidemic of smallpox in a very few years' time, and Rider Haggard's vivid prophetic sketch of the pestilence of 1950 may come true all too soon.

If any one had said thirty years ago that a solemn and scientific sanitary association would be formally endorsing a novel, and advising the public to read it, he would have been simply laughed at, and yet this is precisely what the executive council of the Jenner Association did at its last meeting when it passed a formal resolution

thanking Mr. Haggard for his admirably accurate and able treatment of the vaccination problem and the dangers of the antivaccination crusade in "Dr. Therne," and cordially recommending the book for general reading. And to think that within the memory of nearly all of us novels were solemnly denounced from the pulpit, and fiction and serious thought were regarded as incompatible!

The curious accusation against Dr. Mackay of having reported at an inquest that he had made a complete post-mortem examination of a body and found death due to congestion of the brain, when later investigation showed that the skull had never been opened, has been brought before the Home Secretary. The judge before whom the charge of perjury was brought dismissed it with both brevity and levity as merely a case of "doctors differ," but it has been taken up seriously by many members of the profession, and it is probable that Judge Plowden may have an opportunity to learn that "judges differ" also..

Another medical military hero has just passed away in the person of Sir James Monat, K.C.B., who died a few days ago at the ripe age of eighty-five years. He was surgeon to the immortal "Light Brigade" in the Crimea, and at the battle of Balaklava he bravely went to the assistance of an officer who had fallen in the famous charge, and dressed his wounds as he lay exposed to the terrific fire of the enemy, thus saving his life by checking the hemorrhage from a wounded femoral artery. For this he was honored with the Victoria Cross, and later with a knighthood.

It is truly painful to see how the props are dropping out, one by one, from under the vaunted scientific crusade against alcohol. First came the damaging discovery that the average life-expectation of total-abstainers, as shown in their insurance companies, was below that of moderate drinkers; then came Adami's revolutionary demonstration of the bacillus that causes the celebrated "gin liver," and now Professor Veley of Oxford has detected the organism that produces "faultiness" in rum. Whether it is also responsible for the faultiness produced in the consumers of this beverage it is not yet stated, but that will probably be the next step. We always felt that there was something particularly deleterious about rum, and now we know what it is. The organism is certainly unique in one respect, in that it can live and flourish in a solution containing seventy-five per cent. of absolute alcohol. The secret of this extraordinary power of resistance appears to lie in the dense gelatinous sheath which, in Professor Veley's words, "protects it from its enemy, alcohol, while allowing it to secure the sugar which its nutrition requires." Hence it has been christened with the ingenious name of *coleothrix methystes*, from the familiar *χολος* "sheath," and *μεθυστης*, "a drunkard." What a pity human drunkards—and prohibitionists—can't be trained to secrete such a sheath. It would save their neighbors an immense amount of discomfort.

A most remarkable anomaly has just been discovered at an autopsy held by Dr. Mulqueen in the course of an inquest in South London. This is complete congenital atrophy of one lung. The patient was a man aged forty-two years, who had lived an active life and enjoyed good health until within a few months of his death, which was due to hemorrhage from erosion of a vessel in the wall of a small cavity in his lung. Only one lung, the right, could be discovered; it was enormously enlarged, reaching well over to the left side, and almost completely filling the chest. At the back of the left pleural cavity attached to the occluded and atrophied left bronchus was found a small, dark, cylindrical mass of tissue, supposed to represent the remains of the left lung. Only three other cases of this defect appear to have been recorded, and two of these were in infants which never breathed.

"Kynomania" is the name of a new mental disorder which has just been discovered and described by an Irish physician. Its principal symptoms are the owning of a vicious or dangerous dog, and an utter lack of adequate contrition for the damage inflicted by its bites. The doctor regards this psychosis as most unwarrantably encouraged and aggravated by the present state of the law which allows every dog "one free bite" before it can be proceeded against as a vicious animal and his owner held responsible. We fear it would take rather a large asylum to accommodate all the kynomaniacs.

The *Lancet* is now "booming" Netley, the army medical school, as the proper place for the study of tropical diseases on the ground that its hospital sees nearly three times as much malaria as the Seamen's Hospital.

The great London newspapers are beginning to take an interest in medicine, and their keenness and intelligence is really most gratifying. They have little to say of wonderful cures and astonishing operations by Dr. So-and-so, but every new practical advance, especially in preventive medicine, is promptly and usually most accurately reported. The *Daily Chronicle*, for instance, a few days ago went so far as to devote nearly two columns to a really admirable résumé of the progress of medicine during 1898, while the *Times*' reports of the testimony before the Plague Commission, the Marlborough-House meeting, and the Hatlien lectures upon tuberculosis have been even fuller than those in the medical journals.

Mr. Wm. Cadge, the well-known lithotomist of Norwich, has given the handsome sum of $50,000 to the endowment fund of the Norfolk and Norwich Hospital. This makes $100,000 which he has given to medical charities during the past few years. This noble liberality, with not only his time and services, but also with his hard-earned money, by a medical man, has attracted wide attention and praise in the general press.

Dr. Clement Dukes, physician to the renowned Rugby School of Dr. Arnold and "Tom-Brown" fame, has just read a valuable paper before the Headmasters Association upon the unnecessary damage suffered by children in the process of education. From an experience of twenty-eight years as a school-physician he is convinced that the younger school-children are seriously and even permanently injured by the deadening routine, confinement, and lack of rational planning and adaptation of the

course of study. He urged that the State should insist that every school should have ample grounds for games. He also significantly intimated that school-hours are almost as much in need of regulation as work hours before the passage of the Factory Acts.

The "Life of George Harley, F.R.S.," edited by his daughter, just published, is an interesting record of the life of a successful physician. He was twice compelled to give up his work for a considerable time, first by blindness and then by rheumatic gout, but he managed to recover and return to the attack though badly crippled in both cases. A curious thing about his loss of sight was that in the early days of his recovery he found he had lost absolutely all color perception, but this gradually came back to him. It may be a consolation to those threatened with blindness to learn from as competent a witness as Dr. Harley that "the blind man lives in an ideal world of his own infinitely more beautiful than the world which surrounds him." It was for the benefit of Dr. Harley's wife that Liebig first digested food by artificial means, and thus probably saved her life from typhoid.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Ninety-third Annual Meeting, Held at Albany, N. Y., January 31, and February 1 and 2, 1899.

[Concluded.]

SECOND DAY—FEBRUARY 1ST.

[Continued.]

SECTION IN GENERAL MEDICINE.

DR. B. C. LOVELAND of Clifton Springs read a paper, entitled

LITHEMIA.

Synonyms for this condition are, uricacidemia, the arthritic, or rheumic diathesis, or modified gout. It is responsible for about one-half the functional troubles with which humanity is afflicted, and also for a large proportion of the graver diseases which ultimately result in death. There are two distinct divisions or classes of lithemics, and in each of these classes may develop all, or nearly all, of the various phenomena which characterize the condition. These two classes may with propriety be called plethoric, or over-nourished, and asthenic, or poorly nourished.

The plethoric lithemic is a person of robust habit, usually of ruddy complexion, with a hearty appetite, inclined to be a little over weight, often given to insufficient exercise, and the principal functional manifestations in this class are neurasthenia, cerebral hyperemia, spinal congestion, biliousness, so-called sick headaches, insomnia, and melancholia. If continued till organic changes have occurred here is the proper soil for the development of inflammatory rheumatism, arterial degeneration, apoplexy, paralysis, diabetes, sclerosis of the liver, or general arteriofibrosis, besides many lesser ills. The amount of urine in these patients is usually below three pints in quantity, in twenty-four hours, and the specific gravity will vary from 1024 to 1035, or 1040; it is free from signs of kidney disease unless serious organic change has taken place; it may contain uric acid or oxalate of lime, is darker than normal in color, and shows other signs of concentration. The blood also is concentrated above normal, both in color and in corpuscles. This concentration of the fluids of the body, marked as it is by an excess of uric-acid compounds, plays an important part in that excess of solid matter in the body which marks a man as *old* no matter what his years. It is an easy way out of this condition when the organs are still free from degeneration, and the early discovery of the condition is of great importance.

The first physical landmark which may be noticed as pointing toward the condition of lithemia, the finger-nails, is often overlooked. As they are farthest from the center of circulation earthy substances are deposited there first, hence it is always wise to note their smoothness and brittleness.

The chief factor in correcting this condition is the regulation of the patient's diet and exercise, giving less albuminous foods, more water, more exercise, and cutting off from the dietary any of the cereals, vegetables, or fruits which may be the special cause of indigestion. This may be all that may be required, but where the saturation of the system with the uric-acid elements is sufficiently marked it may be necessary to use some mild alkaline medicine in addition to the dietary measures, and in this case the particular alkali is not important.

The asthenic lithemic is the reverse in physical type from the plethoric, and the most common manifestation in this class is rheumatic gout. Beside this we find chronic degenerations of the kidneys, catarrhal troubles of mucous membranes, either bronchial, nasal, or uterine, and also some forms of muscular rheumatism and neuralgias. Neurasthenia may occur in either type of lithemics. In this class the assimilative processes are feeble, and the uric acid is not from over-ingestion, but from poor assimilation.

We find the same condition of urine, but the blood is poorer in hemoglobin, often containing not over sixty-five or seventy per cent., while the corpuscles may count about normal, or more. If we inquire we will find that these patients never drink water, are never thirsty. In our management of this class a very different diet must be enjoined from that prescribed for the plethoric class.

Water is to be used abundantly, meats, especially lamb and white meats, may be used with more or less freedom as the conditions indicate. Bread, potatoes, and starchy vegetables very sparingly, but all sweets, and all sharp acids, including the sour kind of grapes, strawberries, tomatoes, and pie-plant should be avoided. Small doses of some alkali which the stomach will tolerate should be continued most of the time for months, and every effort in the way of out-door exercise should be employed.

DR. C. M. REXFORD of Watertown presented a paper on

WEAK HEART.

The importance of early recognition and the advantage of prompt treatment upon the occurrence of any sign of failure in the working power of the heart was urged. While heart lesions receive due attention, too often weakness of the heart is regarded as of little consequence because there are no marked symptoms of disease. There was a a time when the study of murmurs was about all there was to the question of heart disease, and these determined prognosis and treatment. Then more attention was paid to valvular changes, and last came the knowledge that the condition of the heart's cavities and its muscular walls was after all the thing which was of most consequence. The principal question is, how strong is the heart, and how much ability has the cardiac muscle to do the work required of it. It can safely be said that the cause of heart failure is not chiefly valvular lesion but is weakness of the myocardium. Whether there is such a thing as serious functional disease without cardiac lesion seems hard to understand, but is, after all, of much less practical importance than is the fact that the so-called functional troubles lead to those which are plainly organic. All hearts are not equally strong; some are inherently weak. It has been said and often quoted that a man is as old as his arteries. If there must be limitations of capacities for activity it is well to be aware of them. It is better for a man to know his weakness than to know his strength. Heart weakness, if neglected, results in dilatation. It is produced by malnutrition and anemia in the young and in overworked adults. It is caused by acute diseases and by excessive use of tobacco and alcohol. It results from violent muscular action and is becoming common among bicycle riders who ride injudiciously. Physical and mental fatigue, care, and anxieties are frequent causes. Treatment of weak heart is satisfactory if attempted early, and if the cause can be removed. Hygienic measures often suffice. Iron and oxygen are the great remedies. The first medicine a physician thinks of when he sees a case of heart disorder is likely to be digitalis. This is no discredit to him, and is a tribute to the remedy, but it must be used with great care and nice discrimination. It helps in dilatation, and if the arteries are contracted it does harm and increases the labor of the heart. Nitroglycerin is the best vascular dilator. Arsenic and strychnin are useful remedies. The coal-tar products are too much used. In pneumonia the great danger is heart failure, and treatment from the first ought to be directed to its prevention. Strychnin is the best general remedy. Strophanthus is better in this disease than digitalis when a heart tonic is needed. Treatment of weak heart generally is hygienic quite as much as medicinal, but ought to be employed early. Heart weakness means possible heart failure. It is probable that soon there will be no such thing known as a functional disease, and surer knowledge will enable us to better appreciate disorders in their inception.

DR. GRACE PECKHAM MURRAY of New York read a paper on

NERVOUS DYSPEPSIA.

Nervous dyspepsia means that dyspepsia which is brought about by a lack of nerve force which prevents the proper functioning of the organs of digestion. Brain exhaustion reacts almost at once upon the stomach. Brain-workers are very subject to dyspepsia. In many such cases among literary people she has given the name of "literary dyspepsia." The position taken while writing cramps the stomach and often interferes with its action. The greatest promotor of this trouble is business worry and anxiety.

The effects of nervous dyspepsia are varied, acting on the secretion of the glands differently. Among symptoms more intimately associated with this condition is vertigo, which may be due to auto-infection from the decomposition of food or its arrested digestion. The treatment varies with the symptoms. When bromid of sodium is not beneficial there is probably associated anemia; then the bitter tonics, especially, nux vomica, should be used. If over-acidity is present, bicarbonate of soda, combined with bismuth, which allays the irritability and hyperesthesia, is of value. In cases in which oxaluria and disturbances of the liver are noted, improvement follows the administration of acids. The results following the use of pepsin are not often satisfactory. In long-standing cases lavage is useful. Electricity is often helpful.

DR. W. P. NORTHRUP of New York read a paper on

PNEUMONIA IN INFANTS; ITS DIAGNOSIS AND TREATMENT.

What are the three most useful symptoms and signs of pneumonia in infants?

By infants I mean those under two years of age; the pneumonia I limit to primary acute bronchopneumonia; by best three signs I mean a limited selection from the multitude of apparently equally important signs, a few which in everyday work, taken in conjunction, serve most often as the base for diagnosis.

The cases I have in mind are not superficial, clearly defined pneumonias, easily recognized by auscultation and percussion, but those beginning centrally and giving but late evidence of their character—cases which simulate meningitis or typhoid the first few days. Given a child acting sick—that is, dull and feverish: it is put to bed. Its symptoms in the first to third days may be, as regards the nerve-centers, dulness increasing to stupor, or great restlessness with slight occasional delirium. Added to this may be rigidity of neck, or general rigidity, and pronounced stupor, making a very fair picture of meningitis. Others, again, a little older, with a pneumonia beginning deep in the lung, working slowly to the surface, lie for days in an apathetic state suggesting typhoid fever.

First, in acute inflammation of the lungs the respiration-pulse-ratio tends to depart from the normal of 4 to 1, and approximate the proportion 3 to 1. That is, instead of 80 and 20 it approximates 120 and 40. This I submit to you as the best one point. It is not new; all textbooks mention it but do not emphasize it.

I have for the sake of emphasis put the last point first. It is taking the three points together that constitutes the aid to diagnosis. The second point I would made is, *fever;* a persistent elevated temperature, whether remittent, intermittent, or uniform.

Third, râles, subcrepitant and crepitant, over a circumscribed area, and more certainly if limited to one side; these would complete the three points. Especially does this apply to infants under one year.

In illustration, let me call your attention to the following case, from my service in the Presbyterian Hospital. The patient was fifteen months old, had not been quite well for two weeks, having a slight cough from which he seemed to be very much improved. Three days before entrance into the hospital he became sick, feverish, apathetic, lying quietly unless disturbed. The bowels were somewhat loose, three or four greenish passages in a day. On entrance, the hospital record says he had slight evidences of bronchitis. These, however, disappeared in two days, and there was nothing to be found in his lungs. In this way he continued for several days. Physical examination negative. He was seen by several physicians, and malaria was suspected: repeated examinations of blood showed no malarial organisms. The temperature made wide daily excursions, in the first eight days making two abrupt excursions from 98° to 105° F., once from 97° to 106°. Up to this time let it be remembered that the physical signs of the chest were negative, and the symptoms were high remitting and intermitting temperature, apathetic condition closely resembling the typhoid state, marked pallor, no enlargement of spleen, rapid respiration. By some, typhoid was suspected, malaria having been ruled out. The interest of the case centers in the fact that the disturbance of the respiration-pulse-ratio was pronounced, and not only approximated 1 to 3, but persistently exceeded it. A summary of all respiration and pulse figures taken every four hours shows the respiration to be 2978 as against 7384; the aggregate figure of all respirations in that time was 8934, whereas the pulse was 7384, showing a difference of 1550, an excess on the side of respiration.

It was on this point that the writer of this paper made the diagnosis at the outset, adhered to it through all the days before the appearance of consolidation, even though the physical signs of the chest were negative, for 3, 5, 7, 9, and 11 days. On the eleventh day a small area of consolidation was found on physical examination over the root of the left lung behind. Its physical signs were, on auscultation, diminished respiratory murmurs on quiet respiration, harsh, rude, or bronchovesicular respiration on forced respiration and coughing. From that time on the case was of no special interest, the crisis taking place on the seventh day of diagnosis, or the eighteenth of disease.

Treatment.—It is not an encyclopedic list that I wish to give, but to emphasize one or two things of importance in the treatment of pneumonia. No treatment directly influences the pneumonic process. There is much that may be done to enable the patient to safely pass through the disease. In the fall service at the Foundling Hospital especially during the epidemic of last December I had special privileges in observing and treating primary acute bronchopneumonia in infants (under two years).

There are again three points I would make as most important in treatment. First, hygienic conditions: fresh air, a large room, changing the patient from one well-aired and freshened room to another in like condition. The temperature of the room should vary inversely as the temperature of the patient; 65° to 68° F. when the patient's temperature is high, and higher—say 70° when the patient's temperature reaches normal. An infant with high temperature and dry skin is in no danger of taking cold. A window should admit fresh air continually. However damp and raw the outer air, the warm walls and furniture of a heated house will temper it to the needs of the child. Nothing so refreshes an infant, nothing is more essential to the condition of the blood, nothing acts more favorably as a heart tonic, than cool fresh air. On the other hand the opposite conditions are these—the infant's crib is closely tented about with blankets, the windows are covered with sheets to keep off draughts, added to this are often in the room numerous relatives, and large gas-jets consuming the oxygen. No fever patient ever caught cold from air coming in contact only with the oval of its face. It is not air going in at its nose and mouth that gives it cold.

Second, the care of the digestion: pneumonia disturbs the infant's digestion; flatulence embarrasses the action of the diaphragm, pressure upward against the heart may determine the unfavorable outcome of the disease. One might formulate the advice, "to cure pneumonia, treat the digestion."

Third, the use of water,—bathing—to save nerve exhaustion—or to put it in another way, to stimulate the nerve-centers. A physician once suffered great remorse because a child developed pneumonia after he had treated it several days for typhoid fever, using baths, carefully regulated feedings, etc. This error in diagnosis probably gave the child its best chance of recovery. I often think it would be well to make a diagnosis of fever and not of pneumonia, so that friends would allow one to treat the patient rationally. I believe in treating an acute bronchopneumonia like a fever patient.

Never have I had anything but encouraging experiences with bathing in pneumonia. Again, I suggest it might be policy to render a diagnosis of fever instead of pneumonia so long as the traditional fear prevails of water and air for pneumonia. Water should be freely administered internally as well. The refreshing cold water on the lips, in the mouth and stomach of a fever patient need only be suggested.

DR. C. DE LA MONTAYNE of Port Ewen presented a paper on

MEDICAL EDUCATION: ITS RELATION TO CLASSICAL LITERATURE.

The speaker referred to many authors whose writings were greatly aided by their knowledge of medicine, such as Holmes and Holland of the United States; the hand of the physician was shown in all their works. Rabelais, the greatest satirist in any language, showed his knowledge of midwifery in "Gargantua" and "Pentagruel." John Brown, the Scotch physician, Charles R. Darwin, Huxley, and others, were assisted by their medical knowledge. Even Homer, in the "Iliad," shows his under-

standing of anatomy. Fleming, Conan Doyle, S. Wier Mitchell, Brown, and others, are medical men whose success is undoubtedly due in no small part to their knowledge of medicine.

DR. A. WALTER SUITER of Herkimer presented a paper on

TONSORIAL HYGIENE, AND STATE CONTROL OF BARBER-SHOP SANITATION.

Dr. L. Duncan Bulkley quotes no less than forty-eight writers who report the occurrence of chancre as a sequence of razor cuts upon the face, and a host of similar cases resulting from infected towels, combs, and brushes. A surgeon or dentist is morally and legally responsible for the absolute disinfection of his instruments before operating, and the barber should be made likewise. In the neighboring Province of Quebec there was issued a circular setting forth the dangers to the public, and the necessity for taking preventive measures. All barbers are directed first to encourage customers to have each his own instruments; secondly, to disinfect the razors, combs, and clippers, with directions for accomplishing this; thirdly, to disinfect the brushes with a two-hours' exposure to the fumes of formalin, etc. (Copies of these instructions can be obtained by applying to the Secretary of the Board of Health of Quebec, No. 76, St. Gabriel street, Montreal.) It is earnestly to be hoped that similar regulations may be promulgated generally through the health boards of all cities and towns.

It must be apparent that there could be no objection to the qualification of the barber as to skill, and to the system of control by State licensure, but it seems very clear that the sanitary regulation of his place of business is so great a public interest and insanitary condition so much a menace to the public health as to bring that part of the subject within the province of a constituted public-health system of authority. Let the proposed examining board make sure that barbers are not ignorant of the principles involved in the required sanitation, after which the local health-officer should be required to make it certain that those principles are faithfully kept in practical application.

DR. SIMON BARUCH of New York read a paper on

HYDROTHERAPY IN CHRONIC DISEASES.

The conscientious physician, in treating acute diseases, lays down certain rules for the guidance of the nurse. In chronic diseases, on the contrary, skilled supervision cannot be obtained, and hence the results are not so favorable. In chronic diseases iron and other tonics are used with uncertain results, and while a positive method of bathing like that of Brand is well understood by physicians, the use of hydrotherapy in chronic diseases has not received sufficient attention. If the enormous vascularity of the skin be born in mind it becomes clear that we have in water a powerful agent in regulating the supply of blood to the skin. It is well known that cold water stimulates the muscular fibers and that warmth relaxes them. When cold water is applied to the skin the cutaneous arterial capillaries contract, while the veins remain unaffected. The result is that the skin has a cyanotic appearance; if the application is prolonged, there follows a necrosis of the tissues by reason of the fact that there is a deprivation of the vascular supply. If the application of cold water be brief, the contraction of the arteries is evanescent. A similar result is obtained from the application of heat; both are cutaneous excitants, whose effects are conveyed to the skin through the medium of water. Water has become popular because we can have any temperature and any duration, and because it can be applied to all portions of the body or to the entire surface. The cutaneous nerve terminals are affected, and they in turn affect the motor tracts to the brain, and this is reflected to the pneumogastric, which produces a deep inspiration and more increased cardiac action. Upon the utilization of this principle is based all the clinical value of hydrotherapy. Physiological as well as clinical experiments demonstrate that excretions and secretions depend upon the circulation, and may be enhanced by restoring the latter when disturbed. Infectious diseases, like typhoid fever and pneumonia, not only have the quantity of urine increased by the judicious use of hydrotherapy, but the coefficient doubled or even tripled. It is well established that certain diseases like gout, rheumatism, and syphilis can be favorably influenced by hydrotherapy. Many cases of a chronic nature where medicinal measures have failed have yielded most happily under hydrotherapy treatment. In chronic cases institutional treatment has become almost imperative. The speaker's records embrace 100,000 treatments in cases of neurasthenia, chloro-anemia, phthisis, gout, rheumatism, dyspepsia, some cardiac diseases, asthma, sciatica, and other neuralgias and neuritis. The applicability of hydrotherapy to these varied diseases was explained by the flexible nature of the treatment which makes it adaptable to the various conditions.

Many institutions have sprung up both in Germany and in this country which are bringing hydrotherapy into disrepute. If water is to occupy a lasting position among remedial agencies it should remain in the hands of medical men. Its theory and technic should be taught in schools and its application demonstrated in hospitals.

DR. GLENTWORTH R. BUTLER of Brooklyn read a paper on

ACUTE GASTRO-INTESTINAL RHEUMATISM.

A brief synopsis was given of three cases in which severe abdominal pain, uncontrollable nausea, and decided constipation were preceded by or alternated with tonsillitis, and the acute articular symptoms of rheumatic fever. Certain considerations were presented which led the reader to conclude that these attacks were due to the varying action of the toxin of the as yet unidentified micro-organism which probably causes rheumatic fever. The principal clinical interest of such cases lies in their differentiation from other acute and painful abdominal affections.

SECTION IN SURGERY.

DR. J. H. GLASS of Utica read a paper, entitled

AN EXPERIMENT IN OVARIAN TRANSPLANTATION.

The experiment consisted in transplanting an ovary from a young girl to a woman who had been previously deprived by operation of both ovaries, and who had, in consequence, suffered considerably in her general health. As a result of this somewhat novel procedure, the woman receiving this donation had improved in her general health, and at the present time, eight months after the experiment, was almost restored, both mentally and physically. Not the least interesting result of the operation was the occurrence of erotic dreams, and of a menstrual flow within a few days.

DR. GEORGE M. EDEBOHLS characterized this result as a product of the imagination of the patient, and added that if it were not so surgeons desirous of performing such operations should take warning, and should be most careful in the selection of those from whom the ovaries are to be taken for transplantation, as it was well known that many women apparently possessing normal ovaries had almost no sexual instinct.

DR. A. PALMER DUDLEY defended the operation, claiming that the results were positive, and no longer purely experimental.

DR. J. W. WHITBECK of Rochester read a paper on

THE ADVANTAGES OF THE SUPRAPUBIC OVER VAGINAL CELIOTOMY.

Nine cases were selected and reported in order to illustrate the chief advantages of the suprapubic route.

DR. H. T. WILLIAMS of Rochester read a paper on

THE ADVANTAGES OF VAGINAL OVER SUPRAPUBIC CELIOTOMY IN CERTAIN DISEASES OF THE UTERUS AND APPENDAGES.

While admitting that the choice of the route must depend upon the surgeon and the individual case largely, he claimed as advantages of the vaginal route: (1) Greater rapidity in operating; (2) less shock; (3) better operative results; (4) the absence of an abdominal scar, and hence of a weak spot to favor the production of hernia.

DR. A. M. PHELPS of New York made some remarks on

LATERAL CURVATURE AND POTT'S DISEASE OF THE SPINE, WITH THE IMPROVED ALUMINIUM CORSET FOR THEIR TREATMENT.

He said that the differential diagnosis between lateral curvature and Pott's disease of the spine was rarely difficult. The spinal column is always flexible in lateral curvature, and rigid in Pott's disease. If, in addition to the rigidity, there were pain when the spine was bent forward, the diagnosis of Pott's disease would be confirmed. Extension and fixation should be the law in the management of Pott's disease, and extension and fixation should also be the law for cases of lateral curvature while the patient is in the upright posture. The aluminium corset is light, cleanly and durable, and the perfection of bracing.

DR. LOUIS A. WEIGEL of Rochester said that most orthopedic surgeons of the present day favor the treatment of lateral curvature of the spine by a combination of bracing and gymnastic exercises. Personally, he did not believe that any form of corset or steel brace was efficient in the treatment of the acute stage of Pott's disease. In this, he combined recumbency with spinal support. From a somewhat extensive experience in the use of aluminium in the manufacture of various orthopedic appliances, he was not disposed to look with much favor on the aluminium corset. The chief objection to it was on the score of durability. His experience had been that coating this metal with shellac, or first silver-plating it, and then japanning it, failed to give protection from the corrosive action of the perspiration.

DR. PHELPS said that by coating the aluminium frequently with a varnish made by dissolving shellac in alcohol, it could be protected from the action of the perspiration, and he knew of one corset that had been preserved by such methods for four years, and he saw no reason why they should not last ten or fifteen years.

DR. JOHN O. POLAK of New York reported

TWO UNIQUE CASES OF VESICOVAGINAL FISTULA,

and described the method adopted for their relief.

DR. E. W. MULLIGAN of Rochester presented a communication on

THE DIAGNOSIS AND SURGICAL TREATMENT OF GALL-STONES.

He directed special attention to the diagnostic significance of pain, on deep pressure, localized over the gall-bladder, and spoke of the frequency with which cholelithiasis was confounded with gastralgia. The operation of incision of the gall-bladder, removal of the calculi, and the return of the gall-bladder into the abdominal cavity, after suture, was associated with a certain amount of risk, owing to the liability of bile escaping into the peritoneal cavity. He therefore preferred the oldest of the three recognized operations—cholecystotomy— as it seemed to him the safest, and the one that had made for itself the best record. However, recent experience had taught him the superiority of using an S-shaped incision in doing this operation. The persistence of jaundice after operation he thought could often be explained by the fact that a small stone in the common duct had been overlooked.

DR. REGINALD H. SAYRE of New York presented a paper, entitled

THE MANAGEMENT OF LATERAL CURVATURE OF THE SPINE.

He expressed the opinion that a large proportion of cases of lateral curvature were the result of rickets or of paralysis, usually an infantile paralysis, while the balance were due to such causes as inequality in the length of the lower extremities, and pelvic inflammation involving the psoas muscle. After the position had been improved as much as possible, apparatus was necessary to maintain this improved posture, and in this work great aid would also be derived from appropriate gymnastic exercises.

DR. WILLIAM B. DE GARMO of New York read a paper on

THE TREATMENT OF UMBILICAL HERNIA.

He said that in operating in these cases it was rarely safe to make the incision in the median line, because the

skin and sac were apt to be intimately united at this point, and because it was not uncommon for the intestine to be adherent to the sac alone this line. Personally, he preferred an elliptical incision with removal of the umbilicus. It was most important to close the wound carefully, with several layers of sutures, employing relaxation sutures to prevent undue tension. After the operation the patient should wear an elastic belt.

DR. D. B. ST. JOHN ROOSA of New York presented a paper on

PANAS' OPERATION FOR] STRABISMUS.

He said that he did not propose to enter on a general discussion of the subject, but simply to bring the attention of the profession to a new operation, one which he thought added very much to our ability to correct strabismus by operation. He was not referring to latent squint. Professor Panas had laid stress on a fact, which had been apparently overlooked, *i.e.*, that strabismus is the result of an abnormal action of the muscles of *both* eyes. In the description of his operation, published last July, Professor Panas pointedly remarked: "The conception of the unilateral character of strabismus, while it is true of the paralytic variety, or that due to contraction of the muscle, is absolutely incorrect as to that which concerns concomitant strabismus." This fundamental conclusion, Dr. Roosa, said, had often been lost sight of in the setting forth of operative procedures for its relief. Professor Panas had operated in 210 cases, 180 of which had been a complete and immediate success. In the remaining 30, there still existed after operation a certain degree of convergence, but in none was there an over-effect. The operation was performed in the following manner: The patient having been placed under the influence of a general anesthetic, the conjunctiva was opened by a horizontal incision, and the tissues thoroughly divided about the sheath of the muscle in the usual manner. It was then taken up on the hook and pulled well outward so that the inner margin of the cornea was on a line with the external canthus. Previous experiments by Dianoux of Nantes had shown that there was no danger of rupturing the tendon by this traction. The tendon was then divided, the wound closed by suture, the operation repeated on the other eye, and both eyes bandaged for twenty-four or forty-eight hours.

DR. HERMAN KNAPP of New York read a paper on

GLIOMA OF THE RETINA.

In this communication he described the additions to our knowledge of this subject since his first paper on the same topic, read before this society thirty years ago. He described in great detail what is now known regarding the histology and pathology of this disorder, and referred briefly to the diagnosis, prognosis, and treatment.

DR. HENRY D. NOYES of New York presented a communication on

MEMBRANOUS CATARACT,

in which he described different types of this affection and exhibited the various instruments which, in his hands, had proved best suited to these different classes of cases. He said that the needle had been first devised by Hays of Philadelphia. For many cases he had found Graefe's iridotomy needle exceedingly useful. Sometimes two knife-needles would be required, in which case one should be used to counteract the traction on the ciliary body while dealing with these thick, tough membranes. The importance of the after-treatment should not be lost sight of.

DR. DANIEL LEWIS of New York read a paper, entitled

THE SURGERY OF MAMMARY CANCER.

Touching upon the danger of amputation of the breast he said that out of the 211 cases in which he had operated by opening the axilla there had been only two deaths and these had occurred in patients who had been septic at the time of the operation. Although a good deal has been said about the risk incurred from dividing the cancerous mass, the difficulty with which cancer could be inoculated even under favorable conditions and the lack of well-authenticated instances of infection with cancer among physicians and attendants upon cancer hospitals made him very sceptical regarding this alleged danger. It is well to remove the fat from the flaps because such tissue has poor vitality, and because its removal lessens the tension on the flaps. An important advance had been made in the treatment of cancer when the drainage-tube had been discarded, as this had often been the means of introducing air into the wound and preventing healing. The fewer ligatures employed the better the chances for rapid union. In dressing these cases a thick layer of cotton should be applied to the well breast and arm, the forearm being left free except for the support of a sling, instead of the more common plan of confining it to the chest. This mode of dressing added materially to the patient's comfort.

DR. ROSWELL PARK of Buffalo followed with a paper, entitled

FURTHER STUDY INTO THE NATURE AND FREQUENCY OF CANCER.

After calling attention to the appalling increase in the mortality from cancer in this State he described some of the results already achieved in the Laboratory of Research recently established by New York State. Those engaged in the work there had succeeded in finding in every specimen of cancer certain peculiar bodies, probably either protozoa or fungi, thus demonstrating, it seemed to him, the parasitic nature of this disease. This view had been confirmed by a series of very interesting and important inoculation experiments.

DR. JOSEPH D. BRYANT of New York then gave a historical sketch of the changes which our knowledge of cancer and its treatment had undergone since 1847, the time when it was the practice to remove the growth alone, or only such malignant manifestations as added greatly to the patient's discomfort. In 1847 Moore had laid down the principle that not only should the breast be amputated, but the incision should be made wide of the disease, and the fascia, glands, and adjacent fatty tissue should also be removed. As late as 1870 Paget had made the statement that he had himself never seen a cure, meaning by

that a case that had remained free from recurrence for a period of ten years. Gross, in 1880, had advocated the complete removal of the axillary contents whenever diseased glands were present, together with diseased tissue elsewhere. At the present time statistics collected from a large number of cases showed that the best results were secured by those who operated widely, *i. e.*, removed not only the mammary gland and fatty tissue, but also the contents of the axilla, except the vessels, a part of all of the pectoralis major, together with the subclavicular, supraclavicular, and subscapular glands. As a result of these improved operative methods the percentage of successful cases had risen from 9, in 1847, to 53 per cent., according to the latest report by Halsted. Dr. Bryant said that he did not regard the size of the tumor as any indication of the degree of infection, nor could any definite period of time be arbitrarily assumed as the limit, beyond which the original growth caused infection. Gross had demonstrated that in 6.5 per cent. of the cases in which the glands of the axilla had become infected the supraclavicular glands were likewise infected. Where the lymphatic glands of the axilla were not palpably involved in the disease at the time of operation the prognosis was better by one year.

Joint Session of Sections to Hear Addresses.

Dr. William Osler of Baltimore presented a paper on

some problems associated with typhoid fever.

[To appear in a future issue of the Medical News.]

Dr. Abraham Jacobi of New York read a paper on

the disinfection of the alimentary canal.

Normally, in the duodenum and jejunum, there are no putrefactive changes. These occur chiefly in the colon, and result in the formation of indol, phenol, skatol, hydrogen sulphid, and other compounds. Carbohydrates interfere with putrefaction, as also does milk to a certain extent. Free acids hinder putrefaction. Facts prove that auto-infection from the intestinal canal does exist. Intestinal antiseptics tend to paralyze bacteria and so prevent them from forming toxins, even though they are powerless to destroy these organisms, and bacteriologists are mistaken when they deny the efficiency of these so-called intestinal antiseptics. Cleansing out the intestinal canal by purgation is of value. Chlorate of potash and tannalbin preparations improve the condition of the mucous membrane of the bowel. Albuminoid putrefaction in the colon requires the use of farinaceous food and the exclusion from the diet of meats.

Evening Session.

the relation of medicine to civilization.

Anniversary address by the president, Dr. John O. Roe of Rochester.

The general advance in scientific knowledge has resulted not from progress in any one department, but from the simultaneous discoveries in each, from the consensus of the sciences as Spencer terms it, each contributing to the advancement of all the others. But no department has contributed so much to civilization in the prolongation of life and the general happiness of mankind as that of medicine.

Attention was then called to the relation of medicine to civilization, noting first, the influence of civilization on medicine, and secondly, the influence of medicine on civilization. Hippocrates was the first to infuse into the spirit of medical philosophy of his time the principle of investigation. Stimulated by this spirit, Alexander the Great founded the Alexandrian Library, which made itself felt in the works of Erasistratus and Herophilus in Medicine and in founding the great schools in Spain and Italy which preserved the science of medicine through the Dark Ages.

Medicine has derived assistance from the other sciences. Herbert Spencer says: "We find that to make a single good observation in the purest of the natural sciences, requires the combined aid of half a dozen other sciences."

In proportion to the investment civilization has derived from no other source so great dividends as it has from medicine; both for the life and health of humanity and the economic prosperity of the race. The importance of sanitary and antiseptic measures in the military service is illustrated by the fact that in the Middle Ages, and down to the time of the Crimean War, it was the rule for a greater number of soldiers to die of disease than from wounds. But in recent years in countries where sanitary measures have been observed the relative fatality due to disease has been greatly diminished. The most notable exception to this is our recent Spanish-American War. Much disease in this case may be attributed to the radical change of climate and an imperfect knowledge of the diseases peculiar to these regions; but by far the most potent cause was the utter disregard of sanitary measures by the War Department.

A new day for medicine is now dawning, when tradition, theory, and authority are no longer potent barriers to human perception; and speculation and metaphysics that have so long engrossed the intellectual world are now vanishing before the light of more substantial reason and methods based upon the discovery and demonstration of facts and their relations to the laws of Nature. This dawning day is the beginning of a new utilitarian era, when belief and experience will be measured by the data of demonstration, determined by the consensus of observation, and reduced to mathematical precision, when the charms of empiricism, the perplexities of individualism, the enigmas of prognosis, and the dark mystery of those protoplasmic laborers of the economy will vanish before the bright searchlight of the X-ray, bacteriology, and physiologic chemistry.

Medical science having fought many battles for life and liberty in the dark valleys of the past now stands a victor on the summit of the Nineteenth Century looking forward into the Twentieth and, like Hannibal of old, shouts exultantly to his brave and daring followers, "Beyond the Alps lies Italy."

THIRD DAY—FEBRUARY 2D.

MORNING SESSION.

The Committee on Nominations announced the following committees for the ensuing year:

Committee on Arrangements: Samuel B. Ward of Albany, William B. Nellis of Albany, and Reynold W. Wilcox of New York.

Committee on By-Laws: H. D. Wey of Elmira, Nathan Jacobson of Syracuse, and F. C. Curtis of Albany.

Committee on Prize Essays: J. M. Van Cott of Brooklyn, Abraham Jacobi of New York, William E. Krous of Buffalo.

Committee on Hygiene: Henry R. Hopkins of Buffalo, George R. Fowler of New York, Ezra H. Wilson of Brooklyn, J. M. Mosher of Albany, George Seymour of Utica, Henry Elsner of Syracuse, M. A. Veeder of Lyons.

Committee on Legislation: Frank Van Fleet of New York, Arthur G. Root of Albany, Ernest Wende of Buffalo.

Committee on Ethics: George McNaughton of Brooklyn, Charles Mason of Peekskill, Louis A. Weigel of Rochester.

Committee on Publication: F. C. Curtis of Albany, W. W. Potter of Buffalo, Charles H. Porter of Albany, Daniel Lewis of New York.

State Board of Medical Examiners: A. Walter Suiter of Herkimer, George Fowler of New York, H. D. Wey of Elmira, Daniel Lewis of New York.

Recommendation for Honorary Membership: W. W. Keen of Philadelphia, Morris H. Richardson of Boston.

Eligible for Honorary Membership: John B. Deaver of Philadelphia, Joseph Eastman of Indianapolis, William Osler of Baltimore.

Delegates were appointed to the following: Ontario Medical Association, Canadian Medical Association, American Electro-Therapeutic Association, Massachusetts Society, Connecticut Society, Vermont Society, New Hampshire Society, Medical Society of New Jersey, Mississippi Valley Association, Medical Society of Virginia, British Medical Association, Florida Medical Association.

Dr. A. Walter Suiter of Herkimer: Your Committee recommends earnestly that the Committee on Legislation of this Society prepare a bill making it a penal offense for any person to obtain from a charitable medical institution gratuitous services by persons financially able to compensate for the same in the same manner that under existing laws it is made a penal offense to obtain money under false pretenses. Your Committee would recommend that the Committee on Legislation be specially instructed to make every effort possible to effect the restoration of the original appropriations of $5000 for the care and maintenance of the State Medical Library and that the cooperation, in this respect, of the Legislative Committee of the Homeopathic and Eclectic Societies be requested.

DR. R. J. WILDING of Malone presented a paper upon

A FORM OF SUTURE SUITABLE FOR ABDOMINAL SURGERY.

DR. GEORGE M. MCCOMB of Frankfort read a paper on

THE LIMITATIONS OF SURGICAL WORK IN COUNTRY PRACTICE.

DR. LOUIS F. BISHOP or New York presented a paper on

THE DIFFERENTIATION OF THE DIFFERENT FORMS OF RHEUMATISM.

Diagnosis of neuritis depends upon the recollection of simple facts of anatomy and physiology. When a nerve is inflamed it is tender on pressure along its trunk. The reflexes are impaired. There are disturbances of sensation over the areas of distribution of the terminal fibers. Theoretically, the differentiation should be easy, but practically it is only made after careful study.

The next differentiation of importance is from the various forms of arthritis in which the rheumatic poisoning is not an active cause. Arthritis deformans is a condition of some rarity. It involves the ends of bone in proliferation, and the joint is finally lost. It must be differentiated from chronic rheumatism. Rheumatoid arthritis is characterized by nutritional disorders, well seen in the marked atrophy of muscles, changes in the joints, etc. It occurs more frequently among women.

From chronic gout the differentiation is easily made by the presence or absence of gouty deposits.

A very troublesome type is the arthritis following infection with the gonococcus; this seems to arise from accidental contact at the time a patient is suffering from a mild attack of rheumatism.

Acute articular rheumatism is a systemic disease with usual manifestations in the joints, but it is abundantly proven that rheumatism may manifest itself more injuriously in other directions.

DR. S. A. RUSSELL of Poughkeepsie presented a paper on

THE SCIENTIFIC ASPECT OF THE MIND CURE,

after which the Society adjourned.

REVIEWS.

DISEASES OF WOMEN. A Treatise on the Principles and Practice of Gynecology. For Students and Practitioners. By E. C. DUDLEY, A.M., M.D., Professor of Gynecology, Northwestern University Medical School; Gynecologist to St. Luke's Hospital, etc., Chicago. With 402 illustrations, of which 47 are in colors, and 2 colored plates. Philadelphia and New York: Lea Brothers & Co., 1898.

THE arrangement of this work is upon the basis of pathology. This is a departure from the old plan by which the subject was classified according to regions of the body. To the reader the arrangement is novel and strange, but to the student and one who considers the volume carefully it has great advantages. The book is divided into five sections. In the first, General Principles are considered, including the physiology of the subject, a clear review of bacteriology and a full de-

scription of methods for securing asepsis and antisepsis. In the matter of diagnosis, the book is thoroughly up to date. The recent work upon the bladder and ureters, which has so greatly enlarged the field of diagnosis, receives adequate attention. The matter of local treatment is also considered, The writer goes fully into the question of the value of topical applications, but has found little evidence of their utility. He describes minor operations in detail, and then proceeds to a full discussion of major operations. Upon the subject of drainage, he believes that when the surgeon is in doubt he should not drain. The author considers the subject of the relation of dress to diseases of women of sufficient importance to merit a separate chapter. This includes the most recent investigations upon the subject, and is of decided value.

In Part II. inflammation is taken up and the distinction between infection and inflammation very clearly brought out. This portion of the book should be of especial value to the student as furnishing a foundation for future studies in diagnosis. Inflammation of the uterus comes in natural order, and the writer treats fully of this most important subject. In the treatment of chronic endometritis, he states that he has used patiently and diligently all methods of topical application which are warranted. He has been disappointed in the results and in some cases has seen positive harm done. In considering pelvic inflammation, he believes that pelvic cellulitis exists, and considers fully the operative treatment by both the abdominal and vaginal routes of this procedure. This part of the book concludes with the discussion of inflammations and disorders of the urinary tract.

Tumors, tubal pregnancy and malformations are considered in Part III. The writer has faithfully tried the electrical treatment of myomata without essential success. He has little confidence in ligation of the uterine arteries and broad ligaments. He believes that vaginal removal of myomata should be given a larger place, and that the uterus should be preserved, if possible, in these cases. An original method of operating for this purpose is fully described. He believes that a very low death-rate for both abdominal and vaginal section in these cases is to be expected. In the treatment of carcinoma of the uterus, hysterectomy is indicated, if the womb is mobile and the surrounding tissues not involved. A very good description of deciduoma malignum is given in this portion of the book. An excellent description of ovarian tumors and their treatment comes next in order. In ectopic pregnancy, the author believes that all cases are first tubal and secondarily found in other portions of the genital tract.

In Part IV. the writer treats of lacerations of the perineum, vagina and cervix. We find here a full reiteration of the teachings of Emmet, with the added material obtained from the writer's experience. He combines with closure of the cervix, curetting. This section is exceedingly well written and thoroughly illustrated by some very good original drawings. In the treatment of displacements of the uterus, the author describes an original operation for anteflexion, which in about fifty cases has given one hundred per cent. of anatomical cures and seventy-five per cent. of symptomatic cures. A full chapter upon massage closes the volume.

Among thinking readers who desire a thoroughly modern book, this should be a valuable and popular work. Those who cannot appreciate efforts at progress may not be pleased with the arrangement of subjects and some of the treatment proposed. We have read the volume with great pleasure, and consider it a thoroughly modern textbook of decided value and a distinct acquisition to the literature upon the subject.

CONSERVATIVE GYNECOLOGY AND ELECTRO-THERAPEUTICS. A Practical Treatise on the Diseases of Women and Their Treatment by Electricity. By G. BETTON MASSEY, M.D., Physician to the Gynecologic Department of Howard Hospital and Late Electrotherapeutist to the Infirmary for Nervous Diseases, etc., Philadelphia. Third edition, revised, and greatly enlarged. Philadelphia: The F. A. Davis Company, 1898.

THAT the number of specialists in diseases of women who are interested in the use of electricity in pathologic conditions of the pelvic viscera is a large one would appear evident from the fact that a third edition of Dr. Massey's book has been called for. Ten or more years ago, when really remarkable results were claimed by well-known and competent experimenters in this department of gynecologic practice, many of the assertions made by the present author would have been received with a just appreciation of his wide experience and a higher value would have been placed upon them than is possible by the clinician of to-day.

During the past three years many learned medical societies have given much time to thorough discussion of the value of electricity in gynecology, and almost without exception, the consensus of opinion has been that its sphere of usefulness is confined to extremely narrow limits. Notably was the discussion by the members of the American Gynecological Society at Boston, in May, 1898, to this effect. For this reason, and because others have signally failed to achieve like results, we find it difficult to accept unreservedly many of the statements made by Dr. Massey in the book before us, for instance (page 106), that a neglected catarrhal metrosalpingitis, particularly of gonorrheal origin, is "as surely curable under positive vaginal applications, assisted by the faradic current and by subsequent intra-uterine treatment, as any similar catarrhal affection elsewhere in the body, the intra-uterine treatment being, of course, carefully employed with a view of increasing the drainage." Likewise, one is apt to evince surprise at the perfect results obtained in the case of a young woman who presented herself for treatment of hypertrophy and prolapse of the infravaginal portion of the cervix (page 188). "The cervix protruded about two inches beyond the vulva. On passing the sound into the cavity of the uterus it entered seven inches. Bimanual examination showed that the fundus was well up in the superior strait. The

condition had lasted two months. The protruding cervix was pushed within the vulva and an intra-uterine application of mercuro-cupric cataphoresis made with 80 milliamperes, followed by primary faradic current." On five subsequent occasions the treatment was repeated, with a current of 40 milliamperes, and two and one-half months from the time the patient was first treated the uterus was normal in size and position.

The Apostoli method of treatment of uterine fibroids is lauded, and instances of remarkable diminution in size, and even of complete cure, are related, so that one finally is forced to wonder why it is that myomectomy or hysterectomy is ever resorted to in these cases, and why, if such results are obtained at the hands of one or a few operators by means of the electrical current, other experienced gynecologists have long since given it up.

There is no gainsaying that the book bears the stamp of sincerity from cover to cover, and that it is the work of a man who believes thoroughly in the soundness of the principles laid down. Though he strives honestly to turn professional opinion back to a worship of its former gods it is a task, we opine, most difficult of accomplishment.

The book contains twelve original full-page chromolithographic plates, and twelve full-page half-tone plates of photographs taken from nature, as well as numerous engravings in the text. The publisher's work has been well done in every respect.

A TREATISE ON DISEASES OF THE EAR. By ALBERT H. BUCK, M.D., Clinical Professor of Diseases of the Ear, Medical Department, Columbia University. Third Revised Edition. New York: William Wood & Co., 1898.

PROFESSOR BUCK'S new edition of his text-book of ear diseases amply meets the demands of those advances in otology and aural surgery which have called the publication into requisition. The book is greatly improved by the use of larger type, more prominent headlines, and wider spacing. In addition the number of special case histories which interfered greatly with the continuity of the text in the previous editions, has been greatly reduced in the new one.

The chapter on the changes in the appearance of the membrana tympani has been much enlarged and given a more prominent position. A special chapter has been devoted to the study of those nasal and pharyngeal conditions which so often play an important rôle in the etiology of ear diseases. The chapters on mastoid disease, its complications, and treatment have been revised and enlarged.

CLEFT PALATE; TREATMENT OF SIMPLE FRACTURES BY OPERATION; DISEASES OF JOINTS; ANTRECTOMY; HERNIA, etc. By W. ARBUTHNOT LANE, M.S. London: The Medical Publishing Co., Ltd., 1898.

THIS is a collection of very practical clinical lectures on varied orthopedic topics, presenting some unique and original ideas. Particularly worthy of note is the theory of the mechanical production of arthritis deformans and the author's advocacy of operative interference in fractures, especially of the oblique variety. This latter procedure we take to be an "operation á outrance" when so sweepingly applied, as Lane would have it. Very sound is the advice given in the lecture on "Some of the Consequences of Wearing Boots." As one of the pioneers in the field of mastoid operations, Lane's experiences epitomized in the lecture on "antrectomy" merit due consideration. This collection presents well some of the advanced ideas of surgery.

THERAPEUTIC HINTS.

For Trigeminal Neuralgia.—

℞ Ext. cannabis indicæ . . . gr. viii
Ac. salicylici . . . . gr. lxxx.

M. Div. in chart. No. X. Sig. One powder three times a day in a cachet.—*Hirschkron.*

Orthoform for Toothache.—This drug, in alcoholic solution, applied on a bit of absorbent cotton to the inflamed pulp of a carious tooth has an immediate analgesic effect which continues for some time. There is no toxic action. —*Hildebrandt.*

Ointment for Stye.—

℞ Hydrargyri oxidi rubri . . . gr. iss
Vaselini . . . . . 3 v.

M. Ft. unguent. Sig. External use.

To Prevent Pitting in Smallpox. — Apply the following solution to the face and neck at frequent intervals so that the parts are kept lubricated.

℞ Hydrargyri chlor. corros. } aa . 3 iiss
Ext. opii }
Spiritus . . . . . *m.* liii
Glycerini . . . . . ʒ ii.

M. Sig. External use.

Of ten patients thus treated by LEBESGUE none showed cicatrices, and the pustules began to dry up on the fifth day.

For Gouty Nephritis.—

℞ Colchicin . . . . . gr. ¼
Quininæ sulphatis } aa . . . gr. xv.
Ext. colocynthidis }

M. Ft. pil. No. XV. Sig. One pill three times a day. —*Phillips.*

For Bronchiectasis with Fetid Expectoration.—PORCELLI recommends the following formulæ for a child twelve years of age:

℞ Plumbi acetatis . . . gr. ⅙–½
Terpin. hydratis . . . gr. ii–v
Pulv. ipecac. et opii . . . gr. iss–iiss.

M. Ft. pil. No. 1. Sig. Three or four such pills daily.

From time to time suspend the above and give this mixture:

℞ Guaiacol } aa . . 3 ii
Liq. potassii arsenitis }
Eucalyptol . . . . . 3 i.

M. Sig. Ten to twenty drops morning and evening.

THE MEDICAL NEWS.

VOL. LXXIV. NEW YORK, SATURDAY, FEBRUARY 18, 1899. No. 7.

ORIGINAL ARTICLES.

PULMONARY AND LARYNGEAL TUBERCULOSIS TREATED WITH ANTIPHTHISIC SERUM T. R., WITH REMARKS ON THE ETIOLOGY OF TUBERCULOSIS.

BY W. FREUDENTHAL, M.D.,
OF NEW YORK.

IN a former paper I have said, with reference to the influence of post-nasal catarrh on the production of pulmonary tuberculosis: "According to our present experience, there is no doubt that infection with tuberculosis most frequently takes place through the respiratory organs. But I agree with Ponfick, with whom, by the way, Ziem also coincides, when he declares that the lungs can no longer be looked upon as the principal organs for the entrance of the tuberculous poison. To me it was always incomprehensible how the tubercle bacillus, during respiration, should penetrate the many tortuous respiratory passages, to finally build its nest at the apices of the lungs, which are so difficult to reach. Why do not other microscopic particles, inhaled in the air, do the same? Why does not soot, for example, not only enter the nose but also all parts of the lungs? If we suppose that tubercle bacilli are drawn away mechanically by the air current, I will not admit that, when inhaled in moderate quantities, they reach the apices of the lungs without their progress being previously checked. Imagine, for the sake of simplicity, the air current passing in a straight direction toward the retropharyngeal cavity. Here it turns at an acute angle, and it would be more than peculiar if the bacteria would not be held there by the moist mucosa. In addition, deeper down the air current is deviated at the entrance into the larynx by the various prominences, such as the epiglottis, arytenoids, etc., and again, and more especially, at the bifurcation of the trachea."

There is still another factor that makes the retropharynx the *locus minimæ resistentiæ*. The different kinds of bacteria, especially the cocci, according to the experiments of Babes, are prone to prepare the soil for the tubercle bacilli. Thus this factor also facilitates the entrance of the tubercle bacillus into the mucosa of these parts. Once having penetrated the lymph-tissue it wanders with the lymph-stream until it gets into the larger lymph-vessels, and finally into the thoracic duct. On its way thither the bacillus is quite frequently hindered or detained by stoppage of the vasa afferentia, etc., and the latent tuberculosis, so commonly met with, originates. On the other hand, the thoracic duct becomes the main source for the further spreading of the germs. From here the infection of the apices of the lungs, the *loci minoris resistentiæ*, proceeds.[1] It is evident that the organism frequently reacts against the invasion of the tubercle bacillus, and the glandular swellings, so common in children, appear. These lymphomata, often nothing else than a consequence of an existing retropharyngeal affection, bear the same relation to this condition as the inguinal bubo does to the primary affection in the genitals.

After bringing many more proofs in confirmation of my theory I came to the conclusion that the hypertrophy of the lymphoid tissue at the vault of the pharynx is nothing more than the expression of this reactionary inflammation. At that time I had overlooked an article by Professor Trautmann of Berlin, in which he says: "Although by careful examination of the hyperplastic tissue at the vault of the pharynx, of the follicles, and of the secretion, neither giant cells nor tubercle bacilli were found, I nevertheless consider tuberculosis the cause of the hyperplasia. . . . A communication made to me verbally by Robert Koch also speaks in favor of tuberculosis being the cause of the hypertrophy. After injection of tuberculin he found at first a rise of temperature, then more swelling and hyperplasia of the lymphoid tissue, and after further injections both disappeared and the hyperplasia was cured, but not until treatment extended over several months."

I cannot mention here all the facts that have been elicited in favor of my theory; I will only say that Pluder and Fischer,[2] in an article that appeared almost on the same day as mine, came to very similar conclusions. They believe that the five cases which they mention must be considered as latent and *primary* tuberculosis. They explain their ideas about the propagation of the tuberculous virus in the system in a very interesting manner, for details of which I would refer the reader to the original paper. I have examined numerous patients and have found

[1] W. Freudenthal: "Kleinere Beitrage zur Aetiologie der Lungen-tuberkulose," *Arch. fur Laryngol.*, Bd. 5, 1896, and *Annals of Otology*, February, 1897.

[2] F. Pluder und W. Fischer "Ueber primäre latente Tuberkulose," etc., *Archiv für Laryngologie*, Bd. iv, page 372.

that a great many have affections of the retropharynx, and that of these a certain percentage show tuberculous lesions in the lungs. I did not draw any definite conclusions in regard to the percentage of cases of phthisis among those affected with nasal and postnasal disease but attempted to show that a direct connection exists between affections of the retropharynx or nose and general tuberculosis; in other words, that the disease commonly called "catarrh" frequently leads to tuberculosis.

Dr. E. Fletcher Ingals of Chicago has asserted that "catarrh" has a tendency to prevent tuberculosis.[1] He says that "38 per cent. of the human family at one time or another suffer from pulmonary tuberculosis, as against about 75 per cent. with diseases of the upper air passages, or nasal catarrh." This is as much as, or even more, than I expected, but he says further, that of these 38 per cent. with tuberculosis comparatively few suffer from nasal disease. Thus, for example, of his 830 cases of pulmonary tuberculosis, only 237, or about 28 per cent., showed some nasal trouble. "Of the 237 cases which make up this 28 per cent. I find that 168 consisted of exostosis and deflection of the septum, which . . . is present in 50 per cent. of all persons of the European race; *therefore many of these would have had no possible influence* in causing the pulmonary tuberculosis." I fail to see the logic of Dr. Ingals' conclusions. Because 50 per cent. of all Europeans have deflections of the septum, must we exclude them from our statistics? Are deflections of the nasal septum to be considered normal because so many civilized people have acquired them? We might as well say that gonorrhea in man is a normal condition because so many cases exist. Deflection of the nasal septum is a pathologic condition which also tends to produce postnasal catarrh and I consider it a very important etiologic factor in favor of our theory. But Dr. Ingals goes on to exclude other possibilities by saying: "Further, my records show that of all the cases of pulmonary tuberculosis, 1272 in number, only 27 of the patients, or about 2 per cent., complained of having had any previous nasal disease, which is 4 per cent. less than the normal average." His position must be very weak if he is forced to fall back on such arguments. Were we to be guided by the complaints of the patient, we would, for instance, still have to treat many cases of persistent headache as malaria and fill the patient with quinin and similar drugs, as we formerly did. We would never be justified in removing polypi, etc., in cases of asthma because the patient does not complain of his nose.

[1] *Annals of Otology, Rhinology and Laryngology*, p. 173, February, 1898.

About thirteen years ago, while pursuing other investigations, I examined the nasal passages of every patient, 500 altogether, that came to the Hospital for the Ruptured and Crippled, this city, and was surprised to notice how seldom the patients complained of their noses. I remember several instances in which grown persons could not breathe through their noses at all, since they were almost hermetically stopped up by numerous polypi, etc., and nevertheless they had no complaints to make. In regard to tuberculous patients, I examined 75 of the consumptives at the Montefiore Home. Of these 37 did not complain at all about the throat or nose, and 38 did, *i.e.*, about half on each side. Of the 37 patients who did not complain, not less than 23 showed marked abnormalties in their nasal passages and in only 14 were there no marked changes at all. Although these statistics are not extensive, I am sure that they will convincingly prove that consumptives suffer from nose and throat troubles, not only as much so, but more than other people. Two thirds of those who did not complain had some kind of affection of the throat or nose, and naturally the others, who did complain, showed lesions of the parts also.

The question of the treatment of tuberculosis with the new tuberculin T. R. has been a burning one since Koch published the result of his experiments with the agent nearly three years ago. It was during the course of certain experiments which I was making with tuberculin T. R. that I came across three publications from Professor v. Leyden's clinic, which almost made me give up my investigations. On looking over these papers, however, they did not seem to me to be altogether exempt from criticism. The first paper was that by Dr. Huber, assistant to v. Leyden, who made experiments with the new tuberculin T. R. on animals, and arrived at the conclusion that it had no therapeutic value. His deductions were contradicted by Professor Brieger, Dr. Petruschky, and others. Still, we must admit that his conclusions were correct in one point, *viz.*, that in one or two of his experiments virulent tubercle bacilli were present in the new tuberculin. But since September, 1897, this defect has been remedied. Nor were his practical experiments on patients more successful. In five advanced cases there was no influence visible. In two cases that were doubtful the status of the patients remained unchanged. In three cases, which were suitable for this treatment, in which, however, the injections were interrupted prematurely, one patient was somewhat improved, while the others remained unchanged. In four cases in which the treatment was specially indicated, the

condition of one patient remained unchanged, the second was almost cured, but only temporarily, as he afterward developed miliary tuberculosis, and the other two were materially improved. Similar results were obtained by Dr. Burghart in the female wards of v. Leyden's clinic. In the same number of the *Berliner klinische Wochenschrift* (p. 146, 1898) Dr. Alb. Raude reports three cases of pulmonary tuberculosis treated with T. R. One patient got worse and died, while the two others improved markedly; one gained six pounds and the other twenty pounds in weight.

In the Berlin "Gesellschaft der Charité-Aerzte" on February 10, 1898, there was a heated debate on this topic. This society was apparently divided into two parties; on the one side was the Institution for Infectious Diseases (Koch, Brieger, Marx), and on the other side were the clinicians. As the result of this discussion it might be said in the words of the president, Dr. Schaper, that one point seems to be evident, *viz.:* that it is effective only in the relatively pure cases of bacillary tuberculosis, not in so-called mixed infections.

Last July, in St. Louis, I had the opportunity to see Dr. Carl Fisch's experiments. He was immunizing horses with this new tuberculin T. R., and he was fairly confident of producing in this way a serum that would contain more antitoxic properties than former serums. All of his experiments were published in the *Journal of the American Medical Association* for October 30, 1897, and, as they seemed to me not only scientific but rational, I gave this antiphthisic serum a trial. I commenced using the injections at the Montefiore Home for Chronic Invalids on February 24, and stopped April 8, 1898. With but few interruptions the four patients received daily injections of ½ c.c. I increased the dose rapidly to 1 c.c., but had to reduce it again in the case of three patients on account of the severe reaction. Only one patient could stand 1 c.c., and that only for a comparatively short time. This patient received injections of the old tuberculin seven years ago in the German Hospital, and he could stand these new injections much better than any of the other three patients. The histories are as follows:

CASE I.—Marcus G., aged forty-one years; occupation, furrier; nativity, Hungary; married. Family history negative. Previous history: Sick since April 1, 1895. Began as inflammation of lungs; four months in bed. August, 1896, hemorrhage; no night-sweats; loss of flesh. At present he coughs much, expectoration is profuse and yellow; no night-sweats; no loss of weight; bowels regular; appetite poor.

Physical examination: Chest flattened; retraction over both clavicles, especially right; expansion slight. Dulness at both apices, especially right. Medium coarse, moist râles over upper right lung. Fine moist râles right interscapular region. Moist râles all over right lung. Vocal resonance increased, right side. Few moist râles on left side anteriorly. Harsh respiration with prolonged expiration. Slight bronchophony.

Status April 8, 1898: Marked dulness over right lung, anteriorly; on left side slight supraclavicular dulness; below clavicle concussion-note normal. Swollen gland over left clavicle. Right lung, posteriorly, dulness to middle of scapula. Left lung, posteriorly, percussion-note normal. Sonorous moist râles all over left lung. Vesicular breathing anteriorly and posteriorly. Patient feels better and sleeps better; appetite better; coughs less. On March 2d 1 c.c. of the serum was injected but on the next day the patient felt very poorly. His temperature rose to 101° F., and the injections, therefore, were stopped for three days. After this he received an injection regularly every day, except once when he was very weak.

Although this case did not seem to me to be one of pure bacillary infection, I must say that the serum treatment had no deleterious effect on his condition. On the contrary, the left side is freer than it was before. The right lung is unchanged, and the patient's weight remained stationary. Bacilli were present in the sputum after treatment was discontinued. As a whole, his condition was perhaps somewhat improved.

CASE II.—S. F., aged twenty-one years; occupation, furrier. Family history negative. Previous history: Always well; eight months previously began to cough and expectorate; pain in chest; hemoptysis, night-sweats, etc. Complains at present of severe cough night and morning; free expectoration, somewhat darker than pus; night-sweats; loss of flesh; appetite is good and bowels regular.

Physical examination: Chest fairly developed, but slightly retracted over clavicles; expansion diminished on both sides. Vocal fremitus slightly increased on left side. Dulness at left apex marked; slight dulness at right apex. Hard breathing over entire upper right lung, with prolonged expiration. Fine and moist râles and occasional rhonchi over the middle of the right lung anteriorly. Prolonged expiration at left apex with coarse moist râles and sonorous rhonchi. Fine and medium râles left side, at the bifurcation of the bronchi behind. Injections were commenced on February 24, 1898.

Status April 8, 1898. Dulness in left supraclavicular region marked; on right side very little dulness. Small crepitant râles, left side, anteriorly, down to third rib; right side, anteriorly, breathing normal. Slight dulness in left posterior supraclavicular region. Breathing, left lung, posteriorly, harsh, with few moist râles. The patient felt about the same as before the injections were commenced. There was an infiltration of both ventricular lips of

the larynx intra-arytenoid space. Ulceration of the left vocal lip.

This case did not run as smoothly as the first one. At the commencement of the treatment the man had laryngitis, which grew worse and later showed distinct tubercular infiltration and ulceration. After receiving 1 c.c. of serum on March 2d, his temperature rose to 102.4° F., and then to 103.3° F. From March 3d to 7th we refrained from giving the injections. On March 8th he again received ½ c.c., but on the three following days he felt so bad that we had to stop them again, a hemorrhage having occurred during the night of March 8th. The ulcerations in his larynx then developed more rapidly and were relieved by daily insufflations of orthoform. When these were omitted the pains in the larynx returned. On March 30th an attack of syncope followed the injection but he recovered promptly. I, therefore, again omitted the serum for three days. He lost 7½ pounds in weight.

CASE III.—P. V. G., occupation, electrician. Family history negative. Previous history: Was well up to 1890; then had bronchopneumonia and was in bed four months. His cough persisted and after being examined he was advised to take Koch's lymph, November, 1890. In May, 1891, he went to the Adirondacks and then to Asheville, where he gained weight up to 145 pounds. At the time of admission he coughed very little and only in the morning. Expectoration was very scanty and yellowish; local sweats on neck; appetite poor; bowels regular. Physical examination: Chest flattened, expansion diminished; vocal fremitus increased on left side. Slight dulness over both apices, especially the left, extending down to third rib. Harsh respiration, with prolonged expiration at left apex. In first, second, and third interspaces, a little internal to the mammillary line, cavernous respiration, and whispering pectoriloquy. Fine, medium-moist râles at left apex. Inspiratory râles at both apices. Fine moist râles at bifurcation of the bronchi posteriorly. Bronchial breathing in left suprascapular region. Status April 8, 1898: Dulness in left supraclavicular region, slight dulness right supraclavicular. Slight dulness left infraclavicular region. Harsh breathing left lung anteriorly. Small crepitant râles second intercostal space, right lung anterior. Dulness left lung posteriorly to middle of scapula, left lung posteriorly. Pleuritic friction-sounds also at the base of lung in left axillary line. Cough has ceased entirely; appetite poor. Feels better.

This patient could stand the injections better than any of the others, probably because he had undergone tuberculin treatment seven years before. There was little or no reaction, his temperature seldom rising above 99° F. For some time he complained of pains in the arms, shoulders, etc., which I consider was due to the injections. His appetite as a rule, was poor, but he secretly indulged in whisky. On the left side a pleurisy set in, which I purposely did not treat at all, but otherwise the condition of his lungs was improved. His weight remained about the same and he was discharged from the Home as he wanted to commence work.

CASE IV.—L. H., aged twenty-five years; occupation, tailor. A brother had died of tuberculosis. Since May, 1897, the patient had had hemoptyses and night-sweats; had lost twenty pounds in weight. He had cough, especially in the morning, and his expectoration was scanty and white. No night-sweats; gaining in weight; appetite good, bowels regular. Both apices were retracted and expansion limited. Dulness over both apices. Tactile fremitus increased on both sides. Harsh breathing right lung anteriorly and prolonged expiration at the left apex. A few fine râles over left bronchus behind. Vocal resonance increased on both sides. Status April 12, 1898: Dulness supraclavicular region, left side; also slight dulness up to upper border of third rib. Dulness over upper portion of the left lung in the axillary line and dulness in the suprascapular region posteriorly. Dulness in the supraclavicular region, right side. Less marked dulness infraclavicular region down to second interspace. Slightly diminished breathing over entire anterior aspect of left lung, accompanied by numerous moist and crepitant râles. Diminished breathing left side posteriorly with many moist râles in the suprascapular and interscapular region. Breathing diminished over entire right lung. A few crepitant râles over upper lobe. Patient's weight, 107½ pounds.

This patient could not bear the serum, and although at times I had hopes that he would become accustomed to it he again and again showed marked reaction, lost in flesh constantly (altogether 10½ pounds) and finally grew worse under the treatment. Urticaria at one time was very marked.

Although these results are not so gratifying as those obtained by Dr. Carl Fisch or by Dr. A. M. Holmes of Denver, nor as unfavorable as those of Dr. F. E. Waxham of Denver, I must say that I am of the opinion that this new serum is a remedy which should be tried much more extensively. When we have a series of hundreds of cases, carefully watched and recorded, we will be better able to pass judgment on its value. Until then all well-observed cases will help to form an opinion, and in furtherance of this object this report is published.

A Good Showing for Columbia.—Graduates of forty-three different medical schools have tried the State examinations in Minnesota during the past ten years. The College of Physicians and Surgeons of this city has the best record of all since no one of her graduates who took the examinations failed to passed at the first trial.

THE RELATION OF THE STATE TO THE CONSUMPTIVE, WITH SPECIAL REFERENCE TO PREVENTION OF THE DISEASE AND STATE CARE OF THE INCIPIENT CONSUMPTIVE.[1]

BY JOHN H. PRYOR, M.D.,
OF BUFFALO, N. Y.

IN a paper read before this society last year I presented briefly some arguments in favor of more thorough prevention from tuberculosis and the necessity for special hospitals near home for advanced cases.

The establishment of a State hospital for incipient consumptives in the Adirondack Mountains on land owned by the State was strongly urged, and State care of these cases advocated. Since that time a resolution authorizing the appointment of a committee of three senators to investigate and report upon the advisability of establishing a State hospital for incipient consumptives in the Adirondacks passed the State Senate, and $500 was appropriated to defray the expense of such investigation. By the adoption of this resolution the State of New York recognized for the first time the importance of considering the matter of tuberculosis in the human being. The Senate Committee has reported strongly in favor of the plan and the results of its investigations are exhaustive and valuable. During the present session of the Legislature a bill has been introduced in the Senate and Assembly, entitled "An Act to establish a State hospital in the forest preserves of the Adirondack Mountains for the treatment of incipient tuberculosis and making an appropriation therefor." A resolution has also been introduced authorizing the State board to publish and distribute literature relative to the infection of tuberculosis and the proper method of prevention.

In view of these facts a brief consideration of the relation of the consumptive to the State is peculiarly appropriate at this time. About 14,000 die from consumption in this State each year. This is equivalent to the depopulation of a small city annually. The death-rate is higher than that of all other infectious diseases combined. About eleven per cent. of all deaths are due to this one disease and approximately one of every five more than twenty-one years of age suffers from it. Accurate, honest reports would increase the figures given. At the lowest estimate there are more than 50,000 consumptives in this State and it is probable that a number as large as our standing army is marching steadily, constantly to the grave. Of the 5,000,000 people now living in New York State about 600,000 will probably die of consumption.

[1] Read at the Ninety-third Annual Meeting of the Medical Society of the State of New York, held at Albany, January 31 and February 1 and 2, 1899.

Of all the causes of suffering, distress, and destitution consumption stands at the head. The public has become accustomed to its slow ravages and results, and the "white scourge" has been accepted as an old and necessary evil. From a humane and economic standpoint the effect is appalling and seems to be everlasting. The physician who is familiar with the woes and hardships of the consumptive is inclined to ask: Is this widespread suffering and enormous loss necessary and tolerable when opposed to all modern ideas and advanced knowledge? Ignorance may make neglect excusable, but knowledge reveals more and more the shameful course of dealing with tuberculosis in an antiquated, obsolete, unscientific manner. The medical profession knows that tuberculosis is infectious, largely preventable and curable at an early stage in a large percentage of cases. How much has this recent advance in our knowledge of the disease benefited the public and the consumptive? The public is not properly protected and the victim's distress is increased because he is shunned and finds it harder to obtain employment. The fortunate avoid the unfortunate and weakly attempt, through selfish interest to force the consumptive into isolation. Education is accomplishing something and boards of health, by the employment of partial measures, prevent, to a certain extent, the spread of the disease.

The number of deaths in this State remains almost stationary in spite of the increase of population. This may be due to special effort but there is room for doubt. It will be found that the general death-rate has decreased as sanitary conditions have improved, but tuberculosis has not diminished relatively with other infectious diseases. Certainly the prevalence of tuberculosis at the present time demonstrates the inadequacy of the methods of prevention employed or a lack of thoroughness in execution. The slight attempts at prevention have naturally failed because they were too limited in scope and have been feebly supported, evaded, or opposed by the medical profession.

The public should demand the same immunity from tuberculosis as it receives from other infectious diseases. Emotional objections in favor of concealment, fatal delay, and selfish interests should be swept aside.

The greatest known menace to public health holds its awful sway unchecked simply because well-known and efficient methods are not employed to combat it. The blame rests upon the medical profession. As the guardians of the health of the State united advocacy would insure radical action and incalculable benefits. If necessary requests and ordinance should give way to law and compulsory enforcement. The

sentimental plea that thorough measures of prevention would prove harsh and add hardship to affliction has cost the State thousands of valuable lives by misleading and deceiving the community. To secure systematic, thorough, and continuous effort the power should emanate from the State.

The State Board of Health can, through legislative enactment, adopt and enforce measures which will prevent; to take the place of local subterfuges which promise little except delusion. Or the matter can be left to a commission to investigate and report upon a consistent plan designed to be obeyed and not evaded. About a century before the cause and nature of tuberculosis were known attempts at prevention in Italy were more determined and more successful than in this day of advanced knowledge and enlightened civilization.

Everywhere a crusade against consumption is winning hearty support, and scientific methods of dealing with the problem will appeal to intelligent beings.

Why should New York State lag behind, and neglect and apathy continue? The time has arrived to listen to the advanced thought and rational appeals of those who have long urged common-sense relief for a vast evil. Isolation is in most instances practically impossible, now, but proper precautions may make it unnecessary. Segregation should be employed among the poor, and special hospitals near large centers of population will furnish the best means for caring for the advanced cases. Better treatment and segregation are thus combined. Registration of cases—instructions to the patient or relatives—inspection of food-supplies, destruction of expectoration, prohibition of promiscuous spitting, and particularly disinfection should be rigidly enforced. Why Boards of Health should be denied information concerning this one infectious disease, and efforts to eradicate should be frustrated may some day be answered. Then the reason may be discussed along with other obsolete ideas, such as the exaggerated importance of heredity and the long list of discarded remedies.

The means of prevention already mentioned and often advised will be incomplete unless combined with or preceded by one of the most important and promising. I refer to the State care of the incipient consumptive. The plan will secure complete isolation before the consumptive becomes a source of much danger and offspring practically made impossible. The patient can be removed from the public before he distributes material sufficient to infect many others. Furthermore, he is offered the only opportunity to recover or receive treatment which promises anything. Ideal isolation can be thus obtained.

The most sanguine expectations based upon efficient modes of prevention can only be realized in the course of time, and meanwhile any interest in the welfare of the consumptive will lead to the inquiry, as to what is done, and what can be done in the way of relief and cure. At present the manner of treatment and assistance received by the consumptive is stupid, inhuman, and unscientific. It can only be compared to the management of the insane in medieval times.

He struggles wretchedly along, as a rule, under palliative, or experimental treatment; tries the last new thing or latest device of quackery; spreads the disease and is shunned by his fellows until work is unobtainable or impossible, and then waits for death in his home or a hospital, where he may infect others or acquire mixed infection himself. He belongs to the only class of afflicted for whom no intelligent provision has been made. The conditions and the circumstances surrounding his distress make him the unique pathetic victim of an anomaly in our system of charities. Every other sufferer is given desired treatment, and a chance to regain health if possible. His only hope lies in a prolonged stay in a favorable climate, and that can only be procured by the well-to-do. Thousands die simply because they are poor and cannot obtain help at the proper time. Useless aid and pauperization is offered when too late. The consumptive should be cared for until he is well, not until he is dead.

We are working at the wrong end of the problem. The idea that consumption is necessarily fatal must be combatted and there can be no good reason why the consumptive alone should be denied any chance to fight for his life. As a rule they are industrious workers and belong to the intelligent class. The distinguished pioneer, Dr. E. L. Trudeau, and many others have shown that fifty per cent. of consumptives recover under suitable sanatorium treatment, and that in a large percentage of cases the condition is improved and life prolonged.

Clinical results furnish the best tests of any climate and the percentage of recoveries depends largely upon the selection of cases. Fortunately the State owns a large tract of land in the Adirondack Mountains, where excellent results have been obtained. What objection can there be to caring for consumptives in the right place instead of the wrong place? One offers nothing, the other much, and the cost is practically the same. Vast sums of money are now expended by individuals, the county, and the city upon the poor consumptive, when it is too late—the same amount could be shifted to a wise purpose.

There are many reasons why the State should as-

sume the care of the incipient consumptive and the objections to such action are easily answered. The proper location for institutions to care for the early consumptive cannot be found in this State except in certain regions more or less removed from the center of population. The crusade against tuberculosis and the treatment of curable cases can only be undertaken by the State because of expense and the necessity for avoiding multiplicity of institutions and the consequent increase of officers and salaries. A well-defined and consistent plan can be followed, appropriations controlled, and advanced scientific treatment and investigation promoted.

The State was forced to assume the care of the insane, feeble-minded, and epileptic, first as a protection to the public from physical violence, and finally to secure more humane and scientific treatment. The new proposition of State aid for the sick is supported by the facts springing from a unique modern social evil. The consumptive requires special treatment in a locality known to be beneficial. No other treatment promises anything. No other class of victims of disease needs this help which only the State can provide.

Isolation is obtained by humanitarian means. One of the most important benefits procurable by State care is education of the individual and the masses. The expense of State care will hurry determined efforts at prevention and the folly of neglecting to attack the cause will appear when the cost of its effects are made plain. Provision for relief will lead to an early diagnosis. This would become of vital importance. It is now receiving slight attention. Under the provision of the bill now before the Legislature every applicant for admission must obtain a certificate from experts appointed as examiners; otherwise any sanatorium will become a home for alleged early consumptives with mixed infection, toxemia, and marked destruction of lung tissue. The dangers of reinfection in institutional life can be obviated by strict precautions for the statistics of Falkenstein, Göebersdorf, and other places furnish complete proof that sanatoriums for consumptives, instead of increasing the disease in neighboring districts, tend to diminish the death-rate to a remarkable degree by education. Investigation seems to show that the cottage or pavilion plan is the most advantageous from every standpoint.

The absence from home and the duration of care will be long. Sufficient time should elapse to secure recovery if possible. While under treatment the patient ceases to be self-supporting; his earnings stop, and others may be left dependent. Now he is cared for about as long when his condition is hopeless. The earning capacity soon ceases forever and the dependents must be assisted indefinitely. In one instance assistance will restore health and earning capacity, or improvement with a probable period of employment. In the other there is prolonged, often useless suffering, continued expense or destitution.

The climate in the Adirondacks is not so widely different from other localities in this State as to preclude a safe return and stay at home after recovery. This constitutes a decided advantage in favor of certain regions in this State.

Again the tendency to recurrence is largely avoided by those who have been educated to discriminate between hygienic surroundings and vicious habits and environments which encourage disease. The skeptical may ask, Will the patients go? There has been no difficulty in that way anywhere. What the consumptive desires is a chance, and every physician of experience has grown weary of the advice to go away and get well, and the pathetic reply from clerk, bookkeeper, business, and professional man, and the wage-earner—"I can't afford it, and therefore must work and die."

The expense per patient should not exceed $250 per year. The Massachusetts State Hospital for Consumptives, recently opened, charges $3.50 per week for those who can afford to pay. Of the first eighty-six inmates, fifty were pay patients. An institution for consumptives in the incipient stage should be largely self-supporting. The following objections to State care have been raised: First, the expense will be enormous. Second, it is a dangerous innovation, and will lead to many demands for the relief of the sick. Third, only a small proportion can be benefited, and the ultimate good will be slight because the disease is widespread.

Two of these objections can be dismissed with brief comment. There are special reasons why the consumptive needs unusual aid. The appropriation asked for at this session of the Legislature is $200,000 to build and equip a hospital for 200 or more patients. There must be a beginning, and it is better to save a few and demonstrate the wisdom of the project than do nothing because more cannot be accomplished. The future expenditure will depend upon the wisdom of the Legislature whether the proposed expenditure is justifiable and opens the way for a new and extravagant use of the State money; this can be considered from a humane and economical standpoint.

The humanitarian side of the question is all summed up in the query, "Shall something be done for the consumptive as well as for others suffering from disease in the only rational way that promises anything, or shall the old, wasteful, cruel let-alone policy prevail?"

On the economic side the presentation of a few figures and statistics supply the best argument. Any estimate of the loss to the State by illness and death must be somewhat inaccurate and only approach the approximate. The method will depend upon individual opinion concerning the theory and technic of statistics. According to the German statistics method, it costs $1500 to rear and educate a citizen, and it is declared to be worth that to the State. If the American be worth only $1000 to this State, and 14,000 die each year from consumption, the first loss will be $14,000,000. The vast majority of consumptives die between the age of eighteen and forty years. Assuming that each would have fifteen years more of earning capacity, and the amount earned is only $500 per year the figures become more startling. Now add the unnecessary expense for illness contributed by the individual and the taxpayer, the cost of aid to the dependents, and the loss by infection and degeneracy of offspring. The preventible loss is enormous—millions upon millions. Can any one doubt that the wise expenditure of only a part of this vast sum during a series of years would make consumption an uncommon disease instead of the saddest thing in the world? How could the State invest more safely, and be more sure of a big return on a purely financial basis? Whether State care will pay can be estimated on the cost and returns for a few.

The expense per patient need not exceed $250 per year, and the average length of stay for early cases should be less than that. Carefully selected cases should yield sixty per cent. of recoveries, and an unknown number should be sufficiently improved and the disease checked long enough to permit renewed employment for an indefinite time. A glance will show that the venture will be remunerative, as it has been everywhere else. Each will be the recipient of special education. If the investment pays the insurance companies in Germany, it should pay the State.

In a special and classical report on pulmonary tuberculosis, issued by the Board of Health of New York City in 1897, the following statement is found: "We are convinced that no factor is so patent to-day in perpetrating that ominous death-list from pulmonary tuberculosis as the lack of proper facilities for the care of the poor of this city stricken with the malady." State care will not create a new expense, but money now misspent by city and county will be used at a proper time and in a sensible manner. The scheme seems vast, but the problem is stupendous. It has assumed proportions of magnitude through years of blindness and neglect. Since the presentation of this project last year, precedent has added strength to the suggestion. Massachusetts has built and recently opened a State Hospital for Consumptives, and other States are moving rapidly in the same direction.

There are hopeful signs that the lead of Europe will be followed, and the "white plague" attacked along modern lines dictated by humane and intelligent ideas. Determined action should be taken now. I believe, in this instance, the intelligent public is in advance of the medical profession. Continued delay is almost incomprehensible. When threatened by cholera or epidemic, fear compels hasty and vigorous remedies regardless of expense—yet the ceaseless and fearfully destructive march of tuberculosis moves on unmolested, except by a small annual crop of medical essays which fail to elicit earnest or lasting attention.

In conclusion, there are strong reasons for the belief that death-rate from tuberculosis can be diminished fifty per cent. in ten years by the enforcement of well known safeguards. The gravity and extent of the evil is so great, and the difficulties to be encountered so numerous that centralization and action by the State will alone give a guarantee of prompt and sure results. Power to enforce and control prevention should be given the State Board of Health on the recommendation of a special State Commission appointed to investigate and report upon the best means designed to check the spread of tuberculosis, should be adopted and placed under the jurisdiction and supervision of the State Board of Health. State care of the incipient consumptive, so far as practicable, should be heartily encouraged. Recognition by the State, of the dread disease, and its duty to human victims is of pre-eminent importance. The proper care of the incipient consumptive is the most vital, philanthropic, and economic problem of our time, and efficient prevention must precede or accompany enlightened relief.

---

*INGROWING NAIL; A COMPARISON OF METHODS OF OPERATION.**

BY EDWARD MILTON FOOTE, M.D.,
OF NEW YORK;
ASSISTANT-SURGEON TO THE VANDERBILT CLINIC.

THE numbers of the "Index Medicus" published during this decade contain more than thirty references to the operative treatment of ingrowing nail. Some of the writers describe operations, original with them no doubt, which have been many times performed and frequently reported in the previous decade, or the decade before that, or for that matter in some other century, for operations for this trouble have been performed since the dawn of surgery.

* Read before the Surgical Section of the New York Academy of Medicine, January 9, 1899. For discussion see page 223.

Amat,[1] a Frenchman, in a short article upon this subject, published in 1889, gives no less than fifty-seven references; while Gosselin, whose ingenious operation has been one of those most frequently rediscovered, said in 1873: "There are few surgical troubles for which so many varieties of local treatment have been proposed. I have counted seventy-five different kinds which have been inspired by the desire to prevent recurrence."

I have no thought to call from oblivion for your malediction the names of these seventy-five inventors. Many of them have long since met the reproaches of their unhappy victims. If the good that some of them suggested had outlived all the evil done by the others there would be no excuse for this review of the subject. Unfortunately, however, within our own time there have been men who, with right and left curved chisels, struck off one side or the other of the toe, including flesh, nail, and possibly a bit of the bone; others are still driving gouges blindly into the matrix, or performing some other barbarous operation.

Several theories have been advanced to explain the occurrence of ingrowing nail. Pointed shoes, neglect of the toes, and a habit of paring away the corners of the nails are generally admitted to be the chief factors of the etiology. They are not, however, the only factors. One of the daintiest women I ever saw had an ingrowing nail on each foot, which for more than a year resisted all her attempts to effect a cure with salves and cotton pushed under the sharp edges of the nails. I operated once upon a girl of thirteen, whose little sister, aged five, had a well-marked depression of the edges of both great toe-nails. Profiting by the experience of her older sister the mother had taken every precaution since the little one's infancy to guard against ingrowing nails. The shoes had always been of the best pattern and the toes were carefully tended, yet there were the edges of the delicate little nails pressing down deep into the flesh ready to cause an ulceration as soon as the least traumatism gave them a start.

When once an ulcer is formed the edge of the nail acts as a foreign body and keeps up the inflammation. Such is the immediate cause of the trouble; and without attempting to settle the ancient dispute as to whether the nail grows down into the flesh or the flesh grows up against the nail we may readily admit that there are three ways in which the cause may be removed. Something may be interposed between the flesh and nail; the nail may be removed from the flesh; the flesh may be removed from the nail. All palliative measures aim at accomplishing their end by one or more of these three methods. Astringents, caustics, cotton, sheet tin, silver hooks, scraping the nail thin and bending up its edges, or paring away the sunken edges are some of the measures of separating the nail and flesh. And one may state with safety that most mild cases can be so cured by these simple means that recurrence will not take place if proper shoes and stockings are worn. Even so humble a part of the body as the side of the great toe should not be wantonly sacrificed.

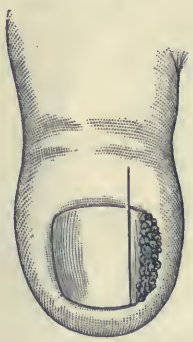
FIG. 1.

Longitudinal section of toe-nail (after Koelliker).

There are, however, aggravated cases in which the habits of the individual or the conditions of his toe make it probable that a cure cannot be obtained by these measures, or if thus obtained that it will not endure. Hence the need of radical operations. They can remove the cause in only two ways. They may permanently remove the edge of the nail; or they may permanently remove the flesh, but a single operation may, of course, do both of these things.

In comparing different methods of operation in order to choose the best it is necessary to remember two things: That every part of the nail grows straight out from the corresponding part of its root,

FIG. 2.



The incision.

and second, that the nail is formed wholly from the reflexion of the skin which lies under its posterior portion back of the curved white line and not at all from the superficial skin which overlies it. The particular portion of the stratum mucosum, the cells of which go to form the nail, is called the matrix (Fig. 1). An operation which fulfills all the requirements of a permanent cure, and with the least damage to the healthy parts, is performed as follows:

Scrub the toe with soap and hot water and disin-

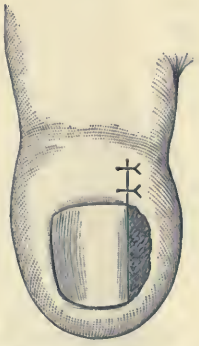
fect it. Tie a strip of gauze tightly around its base to control the circulation and inject 2-per-cent. cocain or eucain solution above and below the edge of the nail to be removed. Disinfect again. Make an incision through nail, skin, and matrix, beginning at the free end of the nail and running parallel to the ingrowing edge. It is not necessary that the strip of nail removed should be more than one eighth of an inch wide (Fig. 2). Reflect the skin-flaps which overlie the root of the nail (Fig. 3). Dissect

FIG. 3.

The flaps reflected.

out the portion of the matrix which is attached to the strip of nail, being especially careful to secure its extreme corner on the side of the toe. If granulations are abundant they may be lightly curetted away. Insert one or two fine black-silk sutures to hold the skin edges in place (Fig. 4). Apply a firm wet antiseptic dressing and a starch bandage. This

FIG. 4.



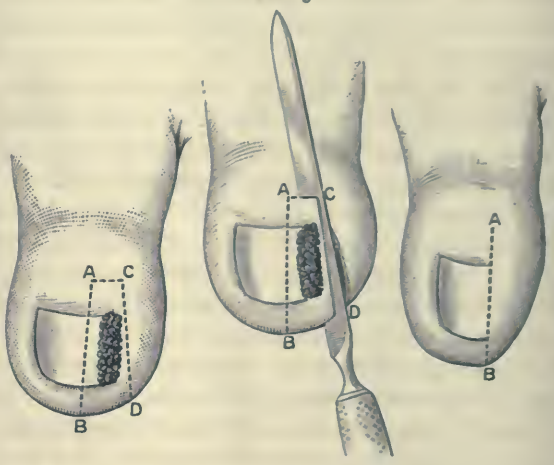
Ready for the dressing.

should be changed every day or two as there is often a minute drop of pus at the junction of the skin and nail. In nearly every case primary union of the skin may be obtained. The patient can wear his ordinary shoes in ten or twenty days.

Could anything be simpler? No tissue is sacrificed which it is not desirable to be rid of. The matrix is removed with certainty. It cannot be curetted or cauterized away without inflicting damage to surrounding tissues. It will not pull out with the nail. The sutures may be omitted and the flaps held in position by the bandage, but a stitch or two insures an exact approximation of the skin edge. The patient does not need to go to bed, but the less he walks for a day or two the better.

The edge of the nail with its matrix has been removed in other ways. One of the best known of these methods is that which was described by Anger before the Surgical Society in Paris, July 17, 1889. He removed a section of the toe from its extremity back to beyond the matrix. As the matrix of the nail in an adult is within one-quarter of an inch of the joint,[3] and in Anger's method the cut extends to the bone, the operation is a pretty serious one. Those who have performed it lately have been inclined to mitigate its severity by making the section V-shaped and extending it only a short distance on the bottom of the toe.[4] That this was not Anger's style will be seen from the drawings (Figs. 5 and 6) which are

FIG. 5.



Anger's Operation (Amiard).

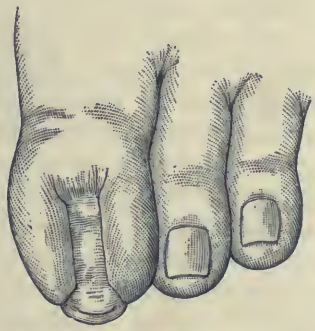
reproduced from a monograph[5] of the method published in the next year, 1890, by Amiard, a pupil of Anger. The illustration of a "cured" toe which he gives makes comment unnecessary.

A still more humane modification of Anger's operation consists in the removal of an elliptical wedge-shaped piece of nail matrix and skin. This operation was practised by Gosselin[6] some thirty years before Anger described the original operation of which it is technically a modification. It is not difficult, makes a small wound, and the amount of skin over the matrix, which it sacrifices, is of little moment perhaps. But it removes the whole gutter along the edge of the nail so that the toe is needlessly mutilated for all time to come, a point which may seem small to the surgeon, but it is one which is of considerable interest to the female patient as I have learned by experience. It was to avoid this defect that I hit upon the method above described,

which is, after all, nothing more than the plainest common sense applied to the plastic surgery of the toe. No one would ever think of removing, with an ingrowing wisdom tooth, the overlying portion of the cheek. Yet that is exactly what is done to the toe in all reported methods as far as I have looked up the literature of the subject.

The second way to keep the nail and flesh apart is to remove the flesh. This may be called, to invert an ancient phrase, taking the mountain away from Mohammed, a principle which, somehow or other, always has its advocates. Chief among them was Cotting. His method was simplicity itself. He sliced off the side of the toe. The nail, or a portion of it, was usually pulled out at the same time in order to give the ulcer an opportunity to heal undisturbed. As the raw surface thus caused is from half an inch to an inch in diameter from three to six weeks are required for its healing. The toe is, of course, permanently deformed, but as it is smooth and more pointed than before the deformity would probably be regarded with favor by most people. The time required for healing is a serious drawback and various surgeons [7] have tried skin-grafting with a considerable amount of success. The graft should not be placed on the fresh wound but applied to the raw surface after a lapse of three or four days.

Fig. 6.

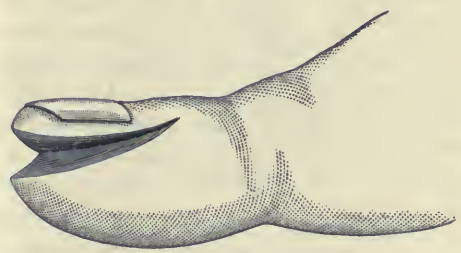


Eighteen months after Anger's operation (Amiard).

A far cleverer method of withdrawing the flesh from the nail was described by Howard [8] of Texas, in 1893 (Fig. 7). His plan was to remove a wedge-shaped piece of skin and subcutaneous fatty tissue right around the toe from one side to the other and to suture the edges of the wound. In this manner the gutters along the sides of the nail are rolled open and the pressure of the nail on the ulcerated skin is relieved. Cartledge,[9] in 1895, and Kane,[10] in 1896, described similar operations, limiting the excision of tissue to the side of the toe which is affected. Such a wound ought to heal quickly and with little discomfort. I have never seen the operation performed and cannot speak of the ultimate results.

All surgery carries with it an element of risk, and last month I was unpleasantly reminded that minor surgery is no exception to this rule. The simple operation described above I performed perhaps ten or twelve times last year. I think there was only one instance in which primary union was not obtained. Just before the holidays a young woman came to me for relief from a deep, stubby, ingrowing nail. She had repeatedly cauterized the granulating area with nitrate of silver, forming a slough, but the infection was apparently slight. With scrupulous aseptic precaution the flap was reflected and the edge of the nail and its matrix removed. The operation was painless, was quickly performed, and there was scarcely any loss of blood. A wet dressing was applied, and the patient, delighted with the lack of deformity, took a train for her home some 300 miles away, expecting to make a holiday of her convalescence. Six hours later intense pain began in the dorsum of the toe and the next day she cut the stitches though they were absolutely clean. The edges of the wound were pulled apart but no pus was found. As the pain continued a doctor was called and a deep incision was made from the middle of the base of the nail to the phalangeal joint, opening a minute abscess cavity. A violent cellulitis followed, there was necrosis of both phalanges, and finally amputation of the whole toe was performed at Johns Hopkins Hospital. The infection was due, I thought, to the hypodermic syringe, the only instrument which was not sterilized by heat; but the patient, who is also a surgical nurse, maintained the opinion that the abscess existed at the time of operation. She was, at the time, much run down in health, having badly overworked herself, so that her power of resistance must have been far below normal. This unfortunate result, while it in no way assists in the determination of the relative merits of different operative methods, shows that there is a certain risk in all attempts at radical cure, which must be remembered when the question to be

Fig. 7.



Howard's operation.

decided is whether palliative measures or an operation shall be resorted to.

THE TREATMENT OF HEADACHE.

By JOSEPH COLLINS, M.D.,
OF NEW YORK;
PROFESSOR OF NERVOUS AND MENTAL DISEASES IN THE POST-GRADUATE MEDICAL SCHOOL; VISITING PHYSICIAN TO THE CITY HOSPITAL.

(Continued from page 168.)

THE headaches associated with the neuroses that we are now considering almost always occur in people whose digestive and assimilative functions are disordered and whose avenues of excretion are more or less sluggish. These derelictions of function demand attention, but it is unnecessary, I believe, to make specific enumeration of the substances employed to encompass such ends. What has been said for the treatment of neurasthenic headaches, applies also for those occurring as a manifestation of the hysterical state, but the treatment of headache which accompanies the other two grand neuroses enumerated in our classification, *viz.:* epilepsy and exophthalmic goiter, require very different drug administration, although the general dietetic, mechanical, and disciplinary measures are the same.

The most important fact in the treatment of epileptic headaches is that those which are the equivalents of an attack should receive the same careful, methodical, persistent bromid treatment as the convulsive form of epilepsy. The indications for medicinal treatment in the preconvulsive form of epileptic headache are the administration of diffusible stimulants, such as the nitrites, and if the cephalalgia precedes the convulsive attacks for any length of time the administration of a large dose of one of the bromid salts. Post-convulsive epileptic headache is best combatted by some such diffusible stimulant as coffee administered in the shape of a hot, black infusion.

The headaches of exophthalmic goiter, which, in reality, are not to be differentiated in their origin or in their manifestations from the headaches of neurasthenia, but which are always of a throbbing character, are best relieved by absolute bodily and mental rest, and by the administration of aconitia in $\frac{1}{200}$-grain doses, repeated every three or four hours if the vascular tension be high, or by the administration of digitalis or its alkaloid in full physiological doses if the pulse be of low tension.

The treatment of headaches accompanying organic disease may be dismissed after very brief consideration, for, as a rule, it may be said that the only form of treatment is operative in all varieties of organic headaches save those due to syphilis and non-pyogenic infection. The latter require treatment directed immediately against the causes.

The headaches of the intoxications and infections may likewise be briefly dismissed. Those accompanying the infectious diseases do not call for any particular treatment aside from the measures taken to combat the infectious processes, while the treatment of headache due to the ingestion of vegetable or mineral poisons resolves itself into the very simple matter of preventing the further imbibition of the poison, be it tea, alcohol, tobacco, or poisonous substances administered therapeutically or encountered in occupations, and the elimination of any of the poison remaining in the system from the body. After that, the headache disappears on the restoration of general, including neural, nutrition. To bring about this restitution of nutrition, general tonic treatment, very similar to that described under neurasthenia, is required. And, meanwhile, the headache may be relieved temporarily by the administration of some of the prescriptions possessing analgesic properties already mentioned. A formulary that I often use as a general tonic and stimulant in headaches following the infections and exogenous intoxications is the following:

Opii pulv.	gr. ss
Zinci phosphid.	gr. ss.

M. Ft. Pill No. 20. Sig. One pill three times a day.

It is to me nothing less than remarkable the tonic effect which one gets from this small quantity of opium. All the infections and intoxications, without exception, produce a more or less profound condition of general anemia, and this anemia must be reckoned with in estimating the nature and determining the treatment of the headache. Early in the treatment of such headaches some such searching tonic as the following should be administered:

℞	Ferri et ammonii citratis . .	grs. xl
	Liq. potassii arsenitis . .	*m.* xl
	Syr. zingiberis	℥ ss
	Inf. calumbæ	ad. ℥ iv.

M. Sig. Two teaspoonfuls after meals.

I am especially apt to give this mixture to children who complain of headaches following the infectious diseases, while for adults the mistura ferri ammonii acetatis is substituted for the citrate salt.

In the treatment of headaches resulting from the

absorption into the system of some endogenous poison, such as that of diabetes, uremia, and the auto-intoxications and infections, the general measures to be adopted do not differ materially from those already spoken of. The headache is combated when the formation of the poison and its absorption into the system is interfered with. In this way diabetic headaches are treated by diet and by the utilization of remedies against the anemia and oligocythemia, while uremic headache is combated by measures that prevent the formation of urea, and by those that facilitate its excretion. In uremic headaches accompanying chronic interstitial nephritis of slow progression, I use the following prescription as a diluent and diuretic with good effect:

℞ Potassii citratis . . . . 3 ii
Tinct. hyoscyami . . . . 3 ii
Spt. etheris nitrosi . . . . 3 ii
Inf. scopariæ . . . . 3 vi.
M. Sig. Tablespoonful in water three times a day.

If it is necessary to increase vascular tension, infusion of digitalis may be added to this mixture.

Headaches arising from such intoxication as that of ammonemia require only local treatment of the cystitis and the institution of measures to combat the anemia.

Headaches arising from auto-intoxication, the original source of the disease being stomachic and intestinal catarrh, functional perversion of the glands supplying the digestive juices, or through the activity of non-pathogenic bacteria, taken in from outside, form an important class, and one that is happily rather amenable to treatment. It must suffice me in this connection to say that after the general measures for the regulation of the alimentary tract and its associated functional dependencies, such as the overcoming of constipation, the adoption of suitable diet in catarrhal conditions, the stimulation of the liver to the production of a suitable kind and amount of bile, the administration of substances that contribute to the restoration of the pancreas and spleen, the treatment consists in the administration of substances that correct the apparent troubles of digestion, and of substances that quell the headache. A favorite prescription of mine for headache associated with flatulency and pyrosis is the following:

℞ Sodii bicarb. } aa. . . 3 i
Bismuthi subgallate } aa. . . 3 i
Pulv. acaciæ } aa. . . 3 i
Liq. ammonii anisi . . . 3 ii
Aqua dest. . . . . ad. ℥ viii.
Sig. Two teaspoonfuls before meals, repeated in three hours if necessary.

In headaches associated with atonic dyspepsia, but without any considerable flatulency, I make use of the following pills, and especially in the headaches occurring in women:

℞ Ferri sulphatis } aa. . . grs. xv
Quiniæ sulphatis } aa. . . grs. xv
Sodii arsenitis . . . . gr. ss
Pulv. rhei } aa. . . . grs. x.
Pulv. zingiberis } aa. . . . grs. x.
M. Ft. Pill No. 12. Sig. One pill three times a day after meals.

The treatment of headaches due to disease of the circulatory system requires considerable discussion, not so much because of their frequency as because of the fact that if they are properly interpreted they yield readily to treatment. The headaches that accompany organic diseases of the heart, whether they be associated with excess or deficiency of propulsive power, naturally require treatment directed to that organ, as does any pulmonary condition which interferes with the return cerebral circulation. Headaches occurring with functional disturbances of the heart are oftentimes very amenable to therapeutic measures, not drugs. For instance, a heart that is working violently as the result of great physical effort or excitation of mind or body, may be so quieted by the application of a simple cold-water compress to the cardiac region that the accompanying frontal throbbing headache disappears promptly, and the efficaciousness of stimulating foot-baths and hot sitz baths in combating a headache of increased vascular tension within the skull is very well known. It is rarely necessary to administer the more powerful cardiovascular depressants in cases of this kind, the required equalizing of the circulation being obtained by hydric procedures and the administration of a few doses of the bromids. When headache is an accompaniment of a sluggish circulation, there being no deficiency in the amount of the blood and no alterations of its constitution, the diffusible stimulants, caffein and strychnin may be relied upon to bring about its prompt relief. Cannabis indica is a drug that I frequently use with good effect in this form of headache. The method of prescribing it is in the following pills:

℞ Ext. cannabis indicæ (English) gr. ⅓ to ss
Ext. gentianæ, q. s.
M. Ft. pil. No. 1.

Headaches that are dependent upon a general anemia are oftentimes extremely resistant to treatment, and although temporary improvement usually follows tonic and stimulating treatment, the anemia must be fought unswervingly for a long time to effect a complete cure, and to stay the recurrence of the headache. These headaches are usually accompanied by a very sluggish condition of the digestive tract, to combat which I have used with very

good results the following combination of tonics and laxatives in the shape of a dinner pill:

℞ Quiniæ sulph. } aa. . . . grs. xii
Ext. aloes aq. }
Pulv. capsici. } aa. . . . grs. vi
Pulv. ipecac. }
Glycerini . . . q. s.
M. Ft. pil. No. 12. Sig. One pill at midday.

Or, if associated with considerable vital depression I use the following pill instead, giving at the same time some absorbable form of iron:

℞ Ext. nucis vomicæ . . . gr. ss
Pil. rhei comp. . . . . gr. iii
Pulv. capsici . . . . gr. ¼.
M. Ft. pil. No. 1. Sig. One pill at midday.

Naturally it is very often necessary to give at the same time, for its immediate effect, some analgesic or a combination of these with a stimulant, such as caffein, and such a prescription as one given above, containing caffein, phenacetin, and salol, usually meets the requirements.

Headaches associated with organic diseases of the blood-vessels, such as arterial sclerosis, arterio-capillary fibrosis, as it is oftentimes called, requires very methodical treatment in addition to the maintenance of the best possible degree of nutrition. Fortunately the number of medicines which are serviceable is very small, being covered practically by iron, nitrite of soda, one of the iodid salts, and occasionally one of the cardiac nervines, such as strophanthus. For the acuter manifestations of such disease, such as violent throbbing in the head, buzzing in the ears, and a feeling as if the head were being dragged forcibly backward the bromids are of service, especially when exhibited in connection with the foot bath, sitz bath, or full bath, to which pine-needle extract has been added. When these measures do not suffice I have frequently seen brilliant results follow the administration of a capsule containing cocain, camphor, and powdered opium, the latter in very small quantity. The value of nitrite of sodium as an agent to dilate the arteries does not seem to me to be sufficiently recognized. It has the great advantage over the other nitrites that it maintains the dilatation of the vessels for about four hours, whereas the action of nitroglycerin and nitrite of amyl is entirely over in less than half an hour. The necessity of recognizing that widespread fatty degeneration is the natural sequence of vascular sclerosis is very apparent, particularly in directing the dietary and physical hygiene of such a patient. Any considerable amount of fatty degeneration is inimical to an active degree of oxidation and as this process is at the basis of tissue metamorphosis and food combustion one must be on the alert not to administer food in such quantities as to clog up the system with effete matters and therefore add another burden to the economy.

We must pass now to a brief review of the treatment of so-called reflex headaches. Although volumes have been written on the subject, it does not seem to me difficult to make judicious disposal of the subject in a few words. Lest it may be gathered that I underestimate the importance of disorder and disease of the sense organs in causing headache, I may say that it is my belief, based upon experience, that from one-third to one-half of all headaches are caused or influenced in their occurrence and maintenance by such conditions. This, however, does not prevent me from saying that the treatment summarized in a few words is, to remove the cause, either by operation or by the application of the indicated orthopedic appliances, such as glasses, and then treat the exhausted state of the nervous system which has been induced through the strain of imperfect organs doing the work for which normal physiological apparatuses were intended. Further than this, one or two facts should be kept in mind. The first is, if the headache dependent upon defective sense organs has existed for a long time, no amount of orthopedic appliances to that organ will vanquish the headache in a considerable proportion of the cases, and furthermore, many cases of headache due to defect in the sense organs require as well general treatment that the permanent cure may be fully encompassed. After having said this, it does not seem to me necessary to say in detail that patients who have astigmatism, hyperopia, insufficiency, etc., should be glassed. No more does it seem necessary to say that chronic turgescence of the nasal mucous membrane, or catarrh of the middle ear should be treated when found associated with a headache whose location and character seem to point to these abnormalities as its source. Such truisms go without saying. In latter years we have heard much of the lack of muscular balance of the eyes as a cause of headache, and a considerable literature has sprung up burdened with the nomenclature of esophoria, exophoria, and hyperphoria. These conditions a few men who claim special skill in overcoming them would have us believe are responsible for a large proportion of all headaches, as well as causative of such profound neuroses as migraine, epilepsy, and Huntington's chorea. But the consensus of opinion of those who have carefully studied the question and who, from their training and experience, as well as from their inherent mental qualities, are entitled to belief, is that such loss of muscular balance, whether due to improper implantation, innervation, or fatigue of certain eye muscles, has been enormously overestimated as a cause of

headache. It is difficult for one who has investigated this matter in an unbiased and critical state of mind to divorce himself from the thought that those who claim to cure so many scores of headaches by almost imperceptible tenotomies of the eye muscles do it for sordid and even less commendable motives.

Space precludes further consideration of the treatment of other reflex headaches, and even though it did not, some of them, such as uterine headache, might be disposed of in a word, *viz.*: put the pelvic organs in as nearly a normal state as possible, then forget the existence of the pelvic organs and center your attention on the individual.

I have previously spoken of a form of cephalalgia to which the name habitual headache is given, and a few words were devoted to a theory of its pathogenesis. It is diagnosticated by process of exclusion. Its treatment is oftentimes an altogether unsatisfactory experience. It is usually associated with evidences of general lowered vitality and disordered functions in other parts of the body. These, of course, must be vigorously combated. Such headache is often accompanied by leucorrhea, and under such circumstances I not infrequently employ the following prescription:

℞ Ammonii chloridi . . . . . gr. lxxii
Fluid ext. hydrastis (non-alcoholic) } aa. ℥ ss
Fluid ext. viburnum opulus }
Elixir simp. . . . . ad. ℥ iii.
M. Sig. Teaspoonful three times a day.

If the headache is accompanied by more or less ovarian pain, I sometimes substitute the bromid of ammonium for the chlorid salt. Taking it all in all, headaches of this nature are to be combated by maintaining the highest possible degree of nutrition, by the occasional employment of symptom medicines that are not opiates to relieve the pain, and by mental suggestion, particularly in those who tend to develop some degree of hypochondriasis.

After thus passing in review the important causes of headache and the necessity for the most searching examination of every system of the body in order to determine its pathologic relationship, it seems to me incumbent on him who writes of headache to say that despite the greatest diagnostic skill and the most herculean therapeutic efforts, the patient often remains in a frame of mind to say, paraphrasing Shakespeare:

> How weary, stale, flat, and unprofitable
> Seem to me all the physic of the world.

MEDICAL PROGRESS.

Hemorrhagic Ascites.—Finny (*Dublin Jour. Med. Sci.*, January, 1899) describes a case in which the effusion of serosanguinolent fluid in the peritoneal cavity necessitated repeated tapping. He was much puzzled by this condition, and for some time was of the opinion that the bleeding was due to the rupture of some vessel in the mesentery or omentum. Hepatic cirrhosis was considered and ruled out, on account of the absence of symptoms pointing to the liver. Before death occurred he inclined to the idea of malignant disease involving the peritoneum, and either the transverse mesocolon or the omentum. The post-mortem examination showed that this last diagnosis was the correct one. The tumor was extremely soft, full of large blood-vessels, and was considered to be of a sarcomatous nature. Neither Finny nor any one of the consultants who examined this patient had ever seen a case of hemorrhagic ascites, and by searching medical literature he was able to find only scanty mention of this symptom. An accurate diagnosis of peritoneal and omental cancer is extremely difficult. The presence of blood-stained ascitic fluid suggests it, but this may also be present in cancer of some of the abdominal organs, for example, the uterus. Cancer of the omentum may occur without ascites, or with ascites which is not bloody. The presence of tumors recognized either before or after tapping is a decided aid to diagnosis, but it may be that an accurate diagnosis cannot be arrived at until the abdomen is opened.

Bursæ of the Hip and Their Diseases.—Zuelzer (*Deut. Zeit. f. Chir.*, vol., 50, p. 148) presents an exhaustive study of the above-mentioned subject with brief histories of fifty-nine cases. In fourteen of these the bursa affected was the bursa iliaca or subiliaca, while in the remainder the bursa trochanterica profunda was the seat of disease. These two bursæ are thus seen to be by far the most important of the bursæ about the hip. Many others have been described by anatomists, of which the subcutaneous bursa over the great trochanter, or the bursa over the insertion of the gluteus medius in the great trochanter, or the bursa of the gluteus minimus in the corresponding situation may serve as examples. Heineke described in all fourteen bursæ about the hip, while a Swedish anatomist, Synnestvedt, found twenty-one with greater or less regularity. Normally these bursæ contain so little fluid that not a single drop can be squeezed out of them, yet they play an important part in the motions of a joint, and thus have not been sufficiently recognized in injuries and diseases of joints. The symptoms produced by inflammation of the subiliac bursa are those of a swelling below Poupart's ligament, which is more or less fluctuating and more or less tense, and may appear in one place, or in more than one, and if the latter the fluid may be pressed from one swelling into the others. The cavity of the bursa may also connect with that of the joint. If inflammation is acute the pain will, of course, be more marked, but by the pressure of the swelling on the crural nerve there may be produced sharp pain in the thigh down to the knee, even though acute inflammation is absent. The thigh is held in a position of abduction, outward rotation and light flexion. This is the typical position; occasionally the limb is abducted and rotated inward. If the position taken is exaggerated by the surgeon no pain is caused. Motion in the opposite direction, whether active

or passive, increases the pain. In narcosis all motions are possible. A coxitis in the early stage shows these same symptoms, but in this disease the flexion is more marked. It is important to remember that in bursitis the trochanter is exactly in Nelaton's line as the limb is not at all shortened. This fact will serve to differentiate bursitis from coxitis with subluxation, and from fracture of the neck of the femur. As bursitis usually follows injury and develops slowly, and as rheumatism, gonorrhea, etc. may also be factors, it frequently happens that the affected thigh measures less in its circumference than its fellow. In bursitis trochanterica profunda the swelling lies at the upper margin of the great trochanter to the outer side of the femur and can reach to the middle of the thigh. Here, too, the limb is held in a position of light flexion, abduction, and rotation, the position which best relieves the affected muscle. This affection can easily be mistaken for coxitis, especially if the bursitis is suppurative, since many cases of coxitis point in the same situation. Careful pressure directly upon the trochanter is not painful in bursitis, nor is pressure upon the anterior or posterior aspects of the hip-joint. In coxitis pressure in any one of these three situations gives pain. Blows upon the heel and walking are both painful in coxitis but not in bursitis. The differentiation in diagnosis between suppurative bursitis and osteitis is more difficult unless a sinus has exposed bare bone. Suppurative bursitis requires an early incision, curetting, and drainage. This should be done early to avoid an extension of the inflammation into the hip-joint. In non-suppurative bursitis, baths, compresses, iodin, massage, pressure, etc., may be employed or the contents may be aspirated and pressure then applied. If these milder measures do not succeed tincture of iodin may be injected into the bursa in order to obliterate its cavity, or better still, it may be laid open and a whole or a part of the sac may be removed. If a bursa communicates with the hip-joint the injection into it of the tincture of iodin will be a dangerous procedure. In radical operations asepsis is of prime importance, else a troublesome fistula may follow.

THERAPEUTIC NOTES.

Dressing for Ulcers of the Leg.—MARCUSE (*Therap. Monatshefte*, December, 1898) recommends the following lotion for particularly obstinate sloughing ulcers of the leg:

℞	Alumin. pulv.	ʒ ij
	Plumbi acet.	ʒ x
	Aq. dest.	℥ xij.

A piece of gauze several layers thick is to be wet with this solution and applied to the ulcer. Other compressors also wet with this solution and larger than the first are laid upon them, and the whole is covered by gutta-percha tissue, and held in place by a firm bandage. This solution has the desirable properties of keeping the wound dry and limiting its secretion for it is a powerful astringent. Furthermore, it is antiseptic, and lastly it has a soothing, cooling effect upon the inflamed leg. It is desirable that the patient lie in bed for a few weeks, though if the ulcers are not too large it is possible to cure them without enforced rest.

Plantar Hypersecretion Cured by the Use of Formalin.—GERDECK (*Therap. Monatshefte*, December, 1898) has had satisfactory results in the treatment of hypersecretion of the sole of the foot by the use of a ten-per-cent. solution of formalin applied morning, noon and night. The tender skin around and under the toes receives only two applications. Usually the third penciling is sufficient to stop all secretion, remove the odor, and leave the skin in a dry, toughened condition. Sometimes a fourth or fifth application may be needed to effect a cure. At the close of treatment four or five drops of concentrated solution of formalin are dropped into each boot. The secretion of sweat begins to show itself in two or three weeks, and by two or three months the treatment will have to be repeated, though in a milder form. Powders containing formalin are not as desirable as the solutions, but they are well adapted to dusting in the boots to take away the disagreeable odor.

The Comfort of a Patient a Factor in His Recovery.—VON LEYDEN (*Centralbl. f. inn. Med.*, December 10, 1898) looks upon the comfort of a patient as an important factor in his recovery. In a certain sense it is a cure of pain. The situation of a patient who has fever, dyspnea, paralysis, or peritonitis, or who is anemic from hemorrhage, etc., is most important. In addition the physician should pay careful attention to the amount and character of the patient's nourishment. The writer warns against the granting of the whims of the patient, and considers it to be the duty of the physician to rouse the energy of the patient rather than to make him effeminate.

Treatment of Granular Conjunctivitis by Salicylic Acid.—MOTY (*La Presse Med.*, December 24, 1898) has used with success in the treatment of the milder forms of granular conjunctivitis a solution of one part salicylic acid to ten parts of sixty-per-cent. alcohol. A bit of absorbent cotton on the end of a probe is wet with this fluid and squeezed a little so that no drops will fall from it. The eyelids are then inverted and held so by one hand, while the wet cotton is passed over the affected portions. Before and after the cauterization, the inner surfaces of the lids are wiped with cotton wet in a mild antiseptic solution. The pain is sharp at first but soon passes away so that patients do not object to the treatment. The cornea is not affected at all by the salicylic acid, and if ulcers are present there is no danger that they will become pigmented by it. The salicylic acid should at first be used every day, then every two days, twice a week, and finally once a week. No other treatment is needed to effect a cure, if there are no complications. The improvement is noticeable at once, even more so than is the case with many other remedies, and it increases as treatment is continued, so that in some months' time, a cure may be effected without interfering in the least with the occupation of the patient, even in long-standing cases with infiltration and vascularization of the cornea.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

J. RIDDLE GOFFE, Ph.M., M.D., Editor,
No. 111 FIFTH AVENUE, NEW YORK.

Subscription Price, including postage in U. S. and Canada.

KISSING THE BOOK.

NOTWITHSTANDING the evident danger of infection and communication of disease involved in the custom, it is still habitual for witnesses in most of our courts of justice to kiss a copy of the Scriptures when taking an oath. It is not required by law, but is left to each witness' own taste in the matter. We have been sincerely pleased to note that the police magistrates in New York have been discussing the question of definitely abolishing the custom in their courts. There is a certain amount of objection to the proposed reform on the part of those who think that an oath loses most of its sanctity in the eyes of a good many people, unless accompanied by some outward sign that connects it directly with the Holy Scriptures. We think, however, that the influence of this superstitious feeling is exaggerated, and that even the most ignorant can easily be made to realize that the obligations of an oath are not lessened by the absence of the Bible.

The custom is so disgusting, considering the promiscuous class of people who follow it, and the opportunities it affords for the spread of the most loathsome diseases, that it is hard to understand how it has endured down to our day. Bacteriologic examinations have demonstrated over and over again a most heterogeneous collection of microbes some of them virulently pathogenic on the covers and leaves of books used for this purpose.

The good woman who, thinking the kiss obligatory, came not long ago to one of the courts with her own copy of the Scriptures, was a most practical and wholesome individual. Let this serious factor in the spread of disease be no longer tolerated. It is a simple thing to do away with the custom; it depends, we believe, entirely on the presiding judicial authority of each court.

TYPHOID FEVER IN PHILADELPHIA.

THE reports of the respective Boards of Health of the cities of New York and Philadelphia for one week each during the month of January are before us In Greater New York, with an estimated population of over three and a half millions, fourteen cases and six deaths from typhoid fever are reported; in Philadelphia, with a population a little over a million, the total number of new cases of typhoid reported is 427 and there were 40 deaths from the disease. Could there be any more bitter reflection on municipal misgovernment than is afforded by such figures? Typhoid is an easily preventable disease. The great cities of the Old World have practically gotten rid of it. Cases of typhoid are extremely rare in Vienna, while in Berlin, as our foreign correspondent noted at the beginning of last year, the occurrence of a case of typhoid in the autopsy-room of the Charité, where nearly 2000 autopsies are performed every year, is such a rarity, that particular attention is called to it and special study made of it as of some curious, infrequent, pathologic condition. A great city of the New World in the midst of our boasted progressive American civilization permits its citizens to be carried off by typhoid year after year and does not wake from the disgraceful lethargy of its criminal negligence.

What a record is that given by our Philadelphia correspondent last week in the statistics of typhoid fever in that city for the last ten years! There has been an average of nearly 3000 cases of typhoid every year and over 500 deaths; and these ten years are almost the last ten years of this enlightened Nineteenth Century, and the last of the ten years is

the worst of them all. Philadelphians are to be congratulated on their long suffering. We hope they will reap a reward for it in another world since it is not the sort of virtue that is rewarded in this. Perhaps for this reason they are satisfied to be hastened out of it aforetime.

If the police department of Philadelphia were to allow 500 people a year to be killed in the streets of the city and some 2500 more to be laid up for months because of the attacks of footpads, would Philadelphians in thorough-going perfect Quaker spirit meekly submit to that too? Or if they dared to protest and their protest was answered by the declaration that the presence of factions in the city council, each one striving to get boodle for itself regardless of citizens' lives and safety, prevented agreement on any plan by which the police might be made more effective, would they shake their tolerant heads and murmur "ah! these city fathers, who can do anything with them?" and then go on about their business hoping they would not be among the next to be waylaid?

The present state of affairs is a blot upon civilization, a crying shame in the face of the world. No Philadelphian should presume to raise his voice in any question of general interest and importance, while the city in which he lives is under this awful cloud. There must be an unlimited supply of the material out of which slaves are made dwelling within the shadow of Independence Hall when this flagrant violation of the inalienable right to health and the pursuit of happiness is allowed to go on year after year and the mass of the people remain indifferent. *Quousque tandem?*

AUTOPSIES, THE ANTIVIVISECTIONIST, AND PAGAN REVERENCE FOR THE DEAD.

ONE of the serious objections, on the score of inhumanity we suppose, that was urged against the management of the General Hospital at Vienna by the zealous antivivisectionists at their recent meeting in Philadelphia, was that an autopsy is performed in the case of every patient that dies in the hospital. Like many statements made by the antivivisectionists this is not entirely true. Only those cases are subjected to autopsy that are expected to furnish some instructive pathologic feature. This condition obtains in the majority of the patients that die in the hospital but by no means all.

As the result of the opportunities afforded in the autopsy-room Vienna, since the days of the great Rokitansky, who either made personally or oversaw 100,000 autopsies it is said, has held the first place in Europe for the study of morbid anatomy and as a consequence also of clinical diagnosis. How many of these carpers at what they do not understand realize how much clearer obscure internal conditions have become as the result of all these autopsies? Each one adds but little, some bring not the slightest mite of addition to our knowledge of disease, but all together they have created the one branch of medical science which to-day rests on a secure scientific foundation—pathology,

The truly senseless phase of this discussion, so conspicuous at the recent Philadelphia meeting, reveals the true inwardness of the antivivisectionist movement and its fanatical opposition, for certain merely sentimental reasons, to scientific advance. Is it any wonder that the medical profession, though most of its members are deeply interested in the prevention of animal suffering and realize certain abuses in experimental work, is opposed to allowing such people any voice in its regulation of animal experimentation?

Unfortunately their claim of a certain inhumanity in the making of an autopsy finds a sympathetic echo in the minds of too many people in America. There is the widespread realization that it is only by the exact study of the nature of disease in the human tissues that any secure advance can come in medicine. Yet when there is a question of autopsy upon a dead friend or even acquaintance there is a feeling of objection that arises and leads, in many cases, to absolute refusal. An example of this has just occurred. A patient suffering from an extremely rare disease, acromegaly, a disease whose pathogeny is as yet very obscure, died recently in a Western town and the friends had the body cremated lest it should by any chance ever come into the doctors' hands.

As a rule patients themselves have not this feeling and are very willing that their bodies should serve, after death, as an object lesson by which other people may be saved suffering and spared to longer life. The feeling of opposition in the matter goes beyond the circle of friends, however, and organizes meth-

ods to keep even the poor who die in hospitals from furnishing at least that much return to medical science for their care and treatment.

This is a false sentiment not engendered by any Christian reverence for the dead. It is a relic of pagan times of what the French call *la culte des morts*, the pagan worship of the dead. The pre-Christian anatomists had to learn whatever of anatomy they could from animals. Dissection of human bodies was a mortal offense. In the midst of the present-day growth of a too sentimental socialism this feeling of supposed reverence for the dead is being allowed to acquire too prominent a place. It should have no weight at all beside that other precious feeling that whatever promises to lessen the sum of human suffering is of the essence of right and goodness and should have no obstacles put in its path. Physicians have many an opportunity to inculcate this lesson in the matter of opposition to autopsies and we fear they do not always improve them with the zeal that their devotion to the cause of scientific medicine should dictate. Our country will not take her place among the nations of the earth as a great contributor to medical science unless ample opportunities are afforded on all sides for the detailed study of disease and its processes.

CEREBRAL INJECTIONS OF ANTITETANIC SERUM.

The good results obtained in the treatment of diphtheria by means of serum-therapy has encouraged similar and persistent attempts in the treatment of nearly all the infectious diseases. Tetanus, one of the most fatal of the entire group, has not been omitted in these investigations. Not content with the comparative failure which attended subcutaneous injections, the antitoxin was tried intravenously, but still the results were by no means promising. The researches of Roux and Borrel, at the Pasteur Institute, Paris, led them to these conclusions: "The tetanus antitoxin, when injected into animals, remains in the blood, whereas the toxin (previously absorbed) is extracted from it and 'fixed' by the nerve-cells. The antidote does not come in contact with the poison, and the two substances, though so near each other, fail to meet. The serum is efficacious against the toxin which is placed under the skin because the greater part of it enters the blood, but it proves powerless against the poison that has already reached the nervous elements." (Dr. Rambaud, in the *New York Medical Journal*, December 17, 1898.) We now readily understand the whole difficulty. The subcutaneous and intravenous injections were productive of so little good merely because they did not reach the seat of trouble save in the minutest amount. As a rule, subcutaneous injections have not been resorted to in cases of tetanus until the disease has been well advanced, that is to say, until a great part of the toxin manufactured by the tetanus bacilli has been "fixed" in the nerve-cells. In order to reach these nerve units, the toxin must travel the route of the circulation, so that when any good has been accomplished by the subcutaneous and intravenous injections, it has been through the neutralizing effect upon these toxins within the circulation, but little if any effect being produced upon the toxins "resting" in and exerting their deleterious action upon the nerve-cells.

If this theory be true, the only hope of success with subcutaneous or intravenous injections lies in their early application, thus keeping the blood in a diluted antitoxic state until all danger of absorption of toxins from the original site of infection is past. If, however, the opportunity for thus combatting the toxin while in the blood-current be neglected, the only hope of reaching it efficiently must be through some method that brings the antitoxin face to face with the toxin in the cells of the cerebrum. Suiting the action to this logical conclusion, the bold experiment was undertaken of injecting tetanus antitoxin directly into the brain substance and with gratifying results. Rambaud has collected reports of twelve cases in which the intracerebral method of injecting tetanus antitoxin was followed, and the results recorded have been far better than those of any other plan of treatment thus far produced—five recoveries. Of these twelve cases, three of the patients were treated in this country, with a mortality of two, but the histories given of the latter demonstrate that neither was a fair example on which to rest the value of the treatment, as one was dying at the time of the injection, while the other, though apparently recovering from the tetanus, succumbed to renal disease, a concomitant of a general septic condition into which the patient had fallen. In the patient who recovered, reported by

Church, the tetanus developed twelve days after the primary injury, a large lacerated wound of the leg produced by glass broken during a severe fall. Six days after the onset, that is to say, when the poison had become fixed in the nerve-cells, antitetanic serum was used subcutaneously, but with little benefit. Improvement being but temporary, it was decided the next day to make an injection of the serum into the frontal lobe of the brain. After trephining the skull, which was done under antiseptic precautions, sixty minims of the serum was slowly deposited to a depth of more than two inches, the entire injection taking longer than ten minutes. The subsequent history was comparatively uneventful, the patient making a good recovery.

If we accept the observations of Roux and Borrel, the neutralizing of the poison stored in the brain-tissue by injection of an antitoxin into this tissue is also to be accepted. Indeed, the good results obtained by means of this method after subcutaneous and intravenous injections have failed, would go far to show that these observers are correct. It would seem, also, that the right thing to do in all cases of tetanus, regardless of their mildness or the reverse—all cases of acute tetanus must be considered grave at any stage—to proceed at once to the intracerebral injection, at the same time not neglecting to neutralize the poison in the blood by subcutaneous or intravenous treatment or both.

ECHOES AND NEWS.

Professor Osler Will Deliver the Cavendish Lecture.—Professor William Osler of Johns Hopkins University has accepted an invitation to deliver the Cavendish lecture for 1899 before the West London Medico-Chirurgical Society.

Hospitals' Bills Rejected.—The Auditor of the War Department at Washington has refused to allow the payment of bills from hospitals for the care of sick and wounded soldiers who were detained under treatment after the muster-out of their regiments.

Dr. Woods Hutchinson Lectures in London.—Dr. Woods Hutchinson, Professor of Comparative Pathology in the University of Buffalo, who is at present studying in London, has accepted an invitation to deliver a series of lectures before the Medical Graduates' College and Polyclinic, London.

Fatal Influenza.—On February 12th a cablegram announced that there are 2342 cases of influenza in Christiania, Sweden, and that there were in the week ending February 12th, 198 deaths from this disease. In Stockholm there were 3194 cases of influenza and 229 deaths during the week ending February 12th.

Oppose Ten-Hour Bill for Drug-Clerks.—At a meeting of the Manhattan Pharmaceutical Association, held in the New York City College of Pharmacy, on February 4th, a resolution was adopted which protests against the passage of the bill introduced in the Legislature by Senator Ford and Assemblyman Maher prescribing a ten-hour working day for drug-clerks.

Hospital-Ship for the Philippines.—The Hospital-ship "Relief" left Washington on the 15th inst., and will proceed to Manila *via* the Suez Canal; she has on board 150 additional hospital-corps men, ten to fifteen acting assistant-surgeons, a number of hospital stewards, and a large quantity of medical supplies for the sick and wounded. The "Relief" will, after reaching Manila, become a floating hospital, for which purpose she is provided with 300 beds.

The Government Hospital for the Insane.—Dr. Godding, Superintendent of the Government Hospital for the Insane at Washington, D. C., makes an urgent appeal for additional accommodations for patients. Since the beginning of the war with Spain 107 insane men from the Army and Navy have been received into the hospital. They include survivors of San Juan and Manila. It is not improbable that 100 more such cases will come in during the next fiscal year. There are now 1927 patients in the institution.

Special Course of Lectures at the Michigan University.—The special annual course of lectures before the Medical Department of the University of Michigan will begin February 25th. Dr. Dock will deliver the first three lectures on "Malarial Fever"; Dr. Cushney will follow with four lectures on the "Mammalian Heart", and Dr. Nancrede will continue the course by four lectures on "Military Surgery," illustrated by his recent experience in the Spanish-American War. The series will be closed by four lectures on "Yellow Fever," by Dr. Novy.

Smallpox Eradicated from Holguin, Cuba.—Captain Woodsoon, surgeon in the Regular Army, reports that the smallpox epidemic in Holguin District has been totally exterminated. The disease had prevailed there for twelve years under the Spanish administration, but was vanquished in three months by the scientific methods of the Army. More than 10,000 persons were vaccinated, and 1200 patients with smallpox were cured. Not a single American soldier contracted the disease, although they did guard-duty at the lazarettos. The sanitary condition of the district is now almost perfect.

Yellow Fever in Cuba.—Dr. R. Echeverria, brigade-surgeon, who was appointed by Governor-General Brooke to investigate the outbreak of disease in the camp of the 202d New York Regiment at Pinar del Rio, reports that the sickness is yellow fever. Dr. Echeverria advises the immediate removal of the camp from its present location. Dr. Doty, the Health Officer of New York, who has re-

cently returned from an inspection tour at Havana, reports most satisfactory progress in cleaning the streets of Havana, and in consequence improvement in the health of the city. He deprecates, however, the great influx of families connected with the Army, and predicts serious consequences provided they remain beyond the limits of the healthy season.

"Passed Away" in Christian Science.—The *New York Times* of February 10th states that Henry Reynolds, sixty years old, living near Tarrytown, New York, died on February 9th from an attack of acute rheumatism. He refused to have a physician called and was frequently visited by a Christian Scientist from New York, who stated there was nothing the matter with him and that his severe pains were imaginary. Shortly after the Christian Scientist's last visit the sick man said he could not see and died within a few hours while sitting in his chair. On February 12th an inquest was held; the verdict was as follows: "Henry Reynolds came to his death from heart failure and a rupture of a hepatic abscess into the abdominal cavity, and we censure John L. Roberts, the Christian Scientist, residing at the Omaha Flats at Sixty-fifth street and Columbus avenue, New York, for neglect to advise the family of the deceased to call a practising physician." Reynolds was worth $200,000.

Program of the Next Meeting of the American Medical Association Already Being Outlined.—At the June meeting of the American Medical Association, in addition to the regular programs, the Section on Ophthalmology and that on Laryngology and Otology will devote the morning of the second day, June 7th, to a joint meeting, under the chairmanship of Dr. Casey A. Wood of Chicago, and of Dr. Emil Mayer of New York. The subject for discussion will be "The Relation of Ocular Diseases to Affections of the Nose and Neighboring Cavities." Four papers are to be read on this subject, *by invitation*, as follows: Dr. Charles Stedman Bull of New York, on "Some Points in the Symptomatology, Pathology, and Treatment of the Sinuses Adjacent and Accessory to the Orbit," Dr. D. Bryson Delavan of New York, on "Nasal Stenoses in Their Relation to Ocular Disturbances," Dr. Joseph A. White of Richmond, Va., on "Eye Troubles Attributable to Nasopharyngeal and Aural Disturbances," and Dr. J. H. Bryan of Washington, D. C., on "Diseases of the Accessory Sinuses in Their Relation to Diseases of the Eye." There will be a general discussion on the main question.

The Massachusetts Hospital for Tubercular Patients.—A supplemental report, dated December 31, 1898, regarding the above institution has been published, showing the admission of eighty-six patients since October 3d, which was the date of reception of the first patient. The hospital is located at Rutland, about twelve miles from Worcester, and is about twelve hundred feet above sea-level. The town wherein it is situated happens to be at the exact geographical center of the State. The hospital is built on the pavilion plan and will accommodate about two hundred beds when fully organized. It is not intended for the incurable. Its physicians say: "It has been a source of gratification and surprise to see how quickly and contentedly the patients have adopted the special hygienic methods used for treatment, namely, almost constant life in the open air, whether by walking or reclining on the piazza, and the ingestion of nourishing food. The remarkable change in the aspect of these patients after even a short stay at the hospital would convince the most casual observer of the efficacy of the treatment upon the general condition of the patient."

Massachusetts has been the first to establish a State institution founded upon the principles of the now great sanitaria in Europe.

Obituary.—Dr. William C. Campbell of New York City died February 5th from pneumonia after an illness of one week. Dr. Campbell was born in Corea, N. Y., August 29, 1854. He was graduated from Princeton University in the class of 1877, and from the College of Physicians and Surgeons in 1880. At the time of his death he was attending physician to St. Luke's Hospital and the New York Orphan Asylum. He leaves a widow and two children. Dr. Campbell was a member of the University and Princeton Clubs, and the Academy of Medicine.—Dr. George H. Rohé of Baltimore died suddenly, February 9th, in New Orleans, whither it is said he had gone to attend a medical society meeting. He was the Superintendent of the Maryland State Insane Asylum, and had been prominent as an alienist and sanitarian.—Dr. James H. Etheridge of Chicago died suddenly in that city from heart disease February 10th. He was Professor of Therapeutics and Medical Jurisprudence in Rush Medical College, ex-president of the Chicago Medical Society, and a member of the American Gynecological Society.—Dr. Henry E. Keyes of New York died suddenly at Ardsley-on-the-Hudson February 6th. After a social function at Ardsley Dr. Keyes and his wife retired to one of the guest-rooms of the Ardsley Casino. At ten o'clock the following morning both were found asphyxiated by gas which had escaped from a gas-stove, unquestionably by accident. Dr. Keyes was a brother of the well-known specialist, Dr. Edward L. Keyes of New York.

Report of the War Commission.—In the report submitted to the President on February 8th by the commission appointed by him to investigate the conduct of the War Department in the war with Spain, it is stated that at the outbreak of the war the Medical Department was altogether unprepared both in men and materials to meet the necessities of the army called out; there was not such investigation of the sanitary conditions of the army as is the first duty imposed upon the department by the regulations; that the nursing force during the months of May, June, and July was neither ample nor efficient, reasons for which may be found in the lack of a proper Volunteer Hospital Corps, due to the failure of Congress to authorize its establishment, and to the non-recognition, in the beginning, of the value of women nurses and the extent to which their services could be secured; the Medical Department was seriously crippled in its efforts to furnish all medical hospital supplies, because of its ina-

bility to have supplies transferred from point to point except through the intermediation of the Quartermaster's Department; that a vast deal of good work was done by medical officers, high and low, regular and volunteer, and there were unusually few deaths among the wounded and the sick. The report recommends: (1) A larger force of commissioned medical officers. (2) Authority to establish in time of war a proper volunteer hospital corps. (3) A reserve corps of selected trained women nurses ready to serve when necessity shall arise, but under ordinary circumstances owing no duty to the War Department except to report residence at specified intervals. (4) A year's supply for an army of at least four times the actual strength of all such medicines, hospital furniture, and stores as are not materially damaged by keeping to be held constantly on hand in the medical supply depots. (5) The change of transportation to such extent as will secure prompt shipment and ready delivery of all medical supplies. (6) The simplification of administrative "paper work" so that medical officers may be able to more thoroughly discharge their sanitary and strictly medical duties. (7) The securing of such legislation as will authorize all surgeons in medical charge of troops, hospitals, transports, trains, and independent commands to draw from the Subsistence Department funds for the purchase of such articles as may be necessary to the proper treatment of soldiers too sick to use the army ration; this to take the place of all commutation of rations of the sick now authorized.

CORRESPONDENCE.

IS THE DAY OF THE DIDACTIC LECTURE A THING OF THE PAST?

To the Editor of the MEDICAL NEWS.

DEAR SIR:—If there is one feature characteristic of so-called movements of reform it is the fact that they go from the extreme which is to be remedied to another extreme which is equally in the nature of an abuse, and the very great improvement which has occurred in laboratory and bedside teaching in the great medical schools during the past few years has put it into the minds of some persons to assert that the didactic lecture should be excluded from the medical curriculum on the ground that it is a relic of what might be called barbarous times in medical teaching.

Recently, with its characteristic ardor, the *Philadelphia Medical Journal* has attacked the subject of the didactic lecture in a way which seems to me is not entirely justified by the facts in the case, and I am glad to note that in a still more recent issue of this journal, Dr. Barton Cooke Hirst, Professor of Obstetrics in the University of Pennsylvania, takes issue with the editorial in question and shows very clearly that the didactic lecture, if properly given, is of very extraordinary value to the student of medicine. To use Dr. Hirst's words: "There is no greater force in medical education to-day than the didactic lecture properly given." And again the lecturer must be able to impart his knowledge to others, must be familiar with the current world literature and should use illustrations which are really illustrative and interesting. These attributes are as necessary to good teaching when given to small sections of a class as they are to didactic lectures given to large bodies of men, and to assert that didactic lectures are so valueless as to be useless, is also to assert that a vast number of didactic lectures dealing with other themes than medicine, are of no possible value. The popularity of lectures upon history, literature, art, and travel attests the fact that people enjoy and learn much by attending them, and in addition to imbibing statements of fact which fall from the tongue of the capable teacher, there is in the medical didactic lecture a possibility for the student to grasp the necessary details, in connection with the lecturer's theme, which are so essential and so valuable in practical medicine.

Few things can be more uninteresting than dry recitations concerning medical topics, and no means of teaching so well as the didactic lecture enables the student to benefit by the personal experiences of the teacher at whose feet he is studying. While it may be the fashion just at present to bring scientifically accurate laboratory methods to the diagnosis and study of disease those who are engaged in the active practice of medicine recognize thoroughly that there is something else equally valuable to the career of a successful physician, and that he must be possessed not only of technical skill but of medical instinct and understanding. There is no better stimulus to this understanding than to follow a course of lectures, such as were given in times gone by by such a man as Dr. D. Hayes Agnew, or at the present time by Dr. J. M. DaCosta, and no one who has heard these masters of medicine can for a moment doubt that it would be unwise to abolish the didactic lecture from the medical course.

Very truly yours,

H. A. HARE, M.D.

PHILADELPHIA, PA., January 25, 1899.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

BLIZZARD WEATHER—TWO UNUSUALLY LONG UMBILICAL CORDS WITH FIVE TURNS AROUND THE CHILDREN'S NECKS—EMBOLISM OF THE POSTERIOR TIBIAL ARTERY BY AN ATHEROMATOUS PLATE—LOCAL BOARDS OF HEALTH—OVERCROWDING OF THE STATE INSANE ASYLUM AT NORRISTOWN—PERSONAL NOTES — OBITUARY — HEALTH STATISTICS.

PHILADELPHIA, February 14, 1898.

THE miniature blizzard which struck Philadelphia last week has caused a vast amount of sickness and distress, particularly among the poor, and reports are coming in from every side of cases of frost-bite, pneumonia, and other maladies incident to such weather conditions as we have had for the past week. Sunday, by special order of the police, "all business incident to the necessities of life may be carried on without interruption," which meant the delivery of coal, groceries, etc., and wagons were to be observed all day Sunday engaged in this traffic. It is to be regretted that typhoid fever cannot be, or rather is

not, checked by cold, for with the thermometer hovering around zero we might look for one blessing to be derived from this storm.

At a meeting of the Philadelphia County Medical Society, held Wednesday evening, February 8th, Dr. J. Torrance Rugh reported "Two Cases of Unusual Length of Umbilical Cord with, in Each Case, Five Turns around the Child's Neck." Both cords measured between fifty and sixty inches, and this Dr. Rugh considered unusual. The longest umbilical cord mentioned in literature measured nearly ten feet. The turns around the neck were unusual, though a case with eight turns has been reported; while this latter complication is more common usually in male children, in these two cases one was a boy and the other a girl, both of whom survived.

Dr. Frederick A. Packard reported a case of "Embolism of the Posterior Tibial Artery by an Atheromatous Plate." The case was interesting because of the visible evidence of an unusual cause of embolism, and the specimen which was exhibited showed a calcareous plate firmly embedded in a white organized thrombus, which completely filled the blood-vessel. This occurred in a middle-aged woman upon whom a diagnosis of an embolus in the thoracic arch of an atheromatous aorta had been made. The plate had probably arisen there, and had been carried down to the posterior tibial artery. Sharp, stabbing, sudden pain was complained of, which became more and more intense. Forty-eight hours later the foot became cold and pulseless. A line of demarcation formed, and suppuration was evidenced by a differential blood-count. Dr. Joseph W. Hearn amputated the leg just below the tubercle of the tibia, but the woman died from exhaustion. Much to Dr. Hearn's and Dr. Packard's surprise the embolus was found just at the point where the artery had been divided. The aorta was found to be atheromatous, and the seat of a large number of calcareous plates. In the discussion which followed Dr. Hearn said that had he known the posterior tibial was involved, he would have amputated above the knee as a matter of course. He described the various kinds of gangrene, and said he wished to go on record as believing that one should not wait for a line of demarcation before operating, especially when sharp, sudden, stabbing pain is complained of, for he believes this to be an infallible sign.

Dr. S. S. Towler of Marionville has introduced a most excellent bill in the Legislature which provides that the school directors of each township shall be constituted a Board of Health, and shall secure the services of some reputable physician to work with them. To the board power must be given to punish all who violate the sanitary laws of the Commonwealth, and to inspect all premises, etc. As the school directors are usually men of the best education in each district, and generally regarded as "lights," this would seem an excellent plan, and a long-neglected want would be supplied.

Following close upon the complaints made that the Philadelphia Hospital is so wretchedly overcrowded, comes the report of Dr. D. D. Richardson of the Norristown State Hospital for the Insane, which shows that over 300 patients are compelled to sleep in the corridors for lack of accommodation. The damage which an epidemic would cause, should it break out in either institution, would be almost incalculable, but as with filtration and other city necessities our politicians seem to know little and care less for the responsibility attached to them. Instead of "the public be damned," it is a case of "the public may die—for all we care."

Dr. John V. Shoemaker, who has recently been appointed Surgeon-General of the State, was presented with a sword by the senior class of the Medico-Chirurgical College last week.

Dr. Edith A. Barker of the Delaware State Hospital has been elected Pathologist to the Norristown State Hospital for the Insane, and her former position has been filled by the election of Dr. Jean Wilson.

Dr. John H. W. Rhein has been appointed Neurologist to St. Agnes' Hospital.

At the annual meeting of the Philadelphia Academy of Surgery, held February 6th, the following officers were elected for the ensuing year: President, Dr. J. Ewing Mears; vice-presidents, Drs. W. W. Keen and John Ashhurst, Jr.; secretary, Dr. William J. Taylor; treasurer, Dr. William J. G. Porter.

Dr. Edward North of Hammonton was killed last Saturday while driving across the railroad tracks near his home. He was a graduate of Jefferson Medical College, a member of the Hammonton Board of Health, and of the Board of Education.

Dr. A. Clark Deakyne died February 5th of chronic Bright's disease. He was a graduate of the old Pennsylvania Medical College, which is no longer in existence.

The total number of deaths occurring in Philadelphia during the week ending February 11th, as reported at the Health Office, was 569, which is an increase of 57 over last week, and of 63 over the corresponding period of last year. Of this number 149 occurred among children under five years of age. The total number of new cases of contagious diseases was 444, reported as follows: Diphtheria, 70 cases, with 20 deaths; scarlet fever, 35 cases, with 2 deaths; typhoid fever, 339 cases, with 41 deaths.

MEDICAL MATTERS IN CHICAGO.

[From Our Special Correspondent.]

OSTEOPATHS—BILL AGAINST THE ISSUANCE OF UNLAWFUL DIPLOMAS—CONCERT FOR THE BENEFIT OF THE PRESBYTERIAN HOSPITAL—DONATION BY MRS. STICKNEY—EXAMINATIONS FOR INTERNES AT COOK COUNTY HOSPITAL—NEW SANATORIUM—CHICAGO LARYNGOLOGICAL AND CLIMATOLOGICAL SOCIETY—TREATMENT OF HEMORRHOIDS BY THE PLASTIC METHOD.

CHICAGO, February 12, 1899.

ACCORDING to the *Chicago Evening Post*, the osteopaths of Illinois are preparing a bill to be introduced in the General Assembly placing this school under the control of the State Board of Health, and providing that each applicant for a certificate to practise shall pass a satisfactory examination in anatomy, chemistry, gynecology,

obstetrics, pathology, bacteriology, and physiology. A section will be inserted in the bill providing that no osteopath shall administer any medicines, either externally or internally, and shall not perform surgical operations. It is believed the measure will meet the approval of the leading osteopaths of the State, and will then remove the objections which were set forth by Governor Tanner in his disapproval of the osteopath bill which was passed at the last session.

Dr. J. A. Eagan, secretary of the State Board of Health, is preparing a bill which provides that it shall be unlawful for any person or association to issue to any of its students or other persons any diplomas or other certificates of qualification in medicine, pharmacy or dentistry unless said person or association shall first obtain permission so to issue said certificate or diploma from the State Board of Health, the State Board of Pharmacy, or the State Board of Dentistry of the State. Violation of the law is punishable by a fine of from $100 to $1000. Another bill regulating the granting of charters to educational institutions provides that the Secretary of State shall not issue charters to persons or corporations for the purpose of conferring degrees, diplomas or other certificates of qualification in the science of medicine, pharmacy, or dentistry, unless the application therefor is approved by the State Board of Health, the State Board of Pharmacy, or the State Board of Dentistry, respectively. This bill also empowers the Secretary of State to revoke the charter of any institution of education upon the recommendation of either of these boards if the recommendation is accompanied by proof that the institution is conducting a fraudulent business. It is said, that these measures have the approval of Governor Tanner.

The fourth annual concert for the benefit of the Presbyterian Hospital was given Monday evening, January 23d. This hospital admits more than 2000 patients annually, requiring an annual expenditure of $100,000. In addition to beds endowed by benevolent persons, it has no less than 65 free beds, and it is said to do more charity work than any other hospital with the exception of the Cook County.

The Elizabeth Hammond Stickney Memorial Building, erected for the nurses of St. Luke's Hospital, was dedicated January 26th. Mrs. Stickney bequeathed $75,000 to the trustees of the hospital, of which $10,000 was to endow a room in the name of her husband, Edward Stickney, a like sum to endow a room in her own name, and the balance, $55,000, to be used in the erection of the Memorial Building for the Training School and for needed improvements in the hospital itself.

The medical profession of Chicago and of Cook County has been deeply stirred over the purpose of the President of the County Board of Commissioners to put examinations for internes at the County Hospital under the supervision of the Civil Service Board. The examinations heretofore have been conducted under the immediate supervision of the hospital staff of physicians and surgeons, who now take their stand conservatively on the ground that the past system has been most satisfactory and that a change which might put the work of examination into other and possibly less-competent hands is to be deprecated. The reasons for the change as advanced by President Irwin are that the hospital staff had been suspected of favoring the applicants from those colleges in which the staff physicians are interested. The one point which concerns the public in all this is, of course, the eminent necessity of maintaining the efficiency of the hospital forces unimpaired. Efficiency is the aim of the Civil Service Commission and the prime purpose of civil service law. If it be true that the hospital physicians have formed a sort of close corporation for the benefit of the particular colleges in which they are interested, the public has a right to know about it and to protest vigorously. But it is hardly likely that men of the rank and reputation of some members of the Cook County Hospital Staff are going to imperil the success of their own work and the strength of their own reputations by permitting the selection of incompetent internes.

One of the strongest arguments advanced for the continuance of the present system of examinations is that the staff of the Cook County Hospital gives its services to the people. To a very considerable extent the reputation of the individual physician is dependent upon the showing which he makes there. On the interne, more than on the attending physician, may depend the success of treatment. The examinations as now conducted are fair and impartial. There is no possibility for collusion. Of course politics is at the bottom of this and it has been the curse of the County Hospital during the last twelve or more years.

Architect R. T. Newberry of this city has prepared plans and specifications and has let excavation and foundation contracts for the Phelps Medical and Surgical Sanatorium to be erected at Battle Creek, Michigan. The building will be 200 by 200 feet and five stories high. It will be fireproof throughout and the outside walls will be built entirely of rough-filled boulders. The cost of the building, exclusive of furnishing, will be about $200,000.

The Chicago Laryngological and Climatological Society was recently organized with Dr. E. Fletcher Ingals as its president and Dr. Melville T. Hardie, secretary. A committee was appointed to draft a constitution and by-laws.

At a meeting of the Chicago Medical Society, held February 1st, Dr. Henry T. Byford presented a paper on "The Treatment of Hemorrhoids by the Plastic Method." He has discarded the ligature in the treatment of hemorrhoids and merely cuts them off and sews the raw surfaces together with silkworm gut as in any plastic operation. Three or four wounds are thus sutured, a part of them in a diagonal or transverse direction, in order that the lumen of the anus may not be contracted. The bowels may be moved at the end of forty-eight hours and the sutures removed in two weeks. The rectum is douched out with plain water after every bowel movement. The essential features of the operation are: (1) the abandonment of the ligature; (2) the employment of silkworm-gut sutures, left long and tied into bundles to facilitate removal and to guide the douche point; (3) the diagonal or transverse direction of the line of suture; (4) keeping the stools liquid and the rectum douched out.

OUR LONDON LETTER.

[From Our Special Correspondent.]

PROGRESS OF THE CRUSADE AGAINST CONSUMPTION —EXTRAORDINARY INSTANCE OF RENTING A MEDICAL DIPLOMA—A NEW PSYCHIATRIC DISEASE—STEWED RATS AS A REMEDY FOR BALDNESS.

LONDON, February 4, 1899.

THE crusade against consumption has evidently come to stay. The newspapers are full of accounts of the methods of German sanatoria, of the classification of tuberculosis as an infectious disease, and last but not least, of the remarkable scheme of our own Nikola Tesla. The movement among the laity is on the whole strictly rational and scientific and there is a most refreshing absence of any trumpeting of sure-cures or wondrous methods of treatment. Fresh air and sunlight are the only remedies recognized and the community in its delight at waking up to find consumption curable, seems ready to support loyally every reasonable measure for the extermination of the disease. Five more county and municipal councils have taken the question seriously in hand this week. One melancholy and distrustful layman breaks the general chorus of hope and congratulations with a bitter complaint against doctors for changing their minds so suddenly as to the seriousness and fatality of consumption, like the man who would not be deprived of the precious doctrine of infant damnation. In the next breath he denounces them for not finding out long ago that consumption could be cured by such simple remedies as air and sunshine.

The comments upon Tesla's extraordinary scheme have been most shrewdly sceptical, the *Westminster Gazette* heading its announcement "Bacilli Killed While You Wait," while the asinine statement of Benedikt of Vienna, who has allowed himself to be interviewed upon the subject, that he anticipates great things from the method "because this is absolutely certain: that Mr. Tesla has succeeded in destroying the bacilli with these currents in his own laboratory," is ridiculed as it deserves to be.

The case of "Dr. Nugent," to which I alluded in my last letter turns out to be even more extraordinary than was suspected. It will be remembered that he was indicted for causing the death of a parturient woman, through failure to recognize an inversion of the uterus. No sooner was his examination begun than it was discovered that the prisoner's name was not "Nugent" at all, although he possessed a diploma and registry number in that name, and further investigation revealed a most remarkable state of affairs. The man's real name was proved to be Julian Rowland, a surgeon's dispensary assistant, and when some ten years ago one of his chiefs named Nugent went abroad, he conceived the brilliant scheme of *renting* his diploma and registry number. On the strength of this useful document he had gone to another part of London and conducted an active practice for eight years, regularly paying the munificent sum of *eighty-seven cents* per week to the wife of the real Dr. Nugent. It seems incredible that this Pinafore-like performance could have gone on for eight years under the very nose of the General Medical Council and the Medical Defence Union but it did. It seems that the representatives of the latter body had found out that Dr. Nugent had left England for more than two years and had had his name removed from the register. Then for some reason a delay occurred and Rowland rose to the emergency, posted over to Ireland with his "hired" qualifications, got them registered there, and when the Medical Defence pounced on him, smilingly displayed his Irish registry number and assured them that he was a totally different Dr. Nugent from the man who had gone abroad. However, "its a long lane" and "Dr. Nugent" will now have abundance of time to "get up" his subjects for a genuine licentiate examination, as he has been awarded six-years' penal servitude—three years for manslaughter and three for perjury.

Another way of evading the Medical Practice Acts has also been revealed this week in connection with a malpractice suit. This was a "Medical Hall," which was opened by an enterprising chemist who made an arrangement with a qualified physician of the seedy stripe to "cover" his operations by signing his prescriptions and making the first visit to his patients. All went well in this particular establishment until the doctor got drunk and failed to recognize a senile pneumonia in an old woman whom his assistant went on treating for a cold until she rather suddenly died. This the family not unnaturally resented and insisted upon an inquest, when the whole precious arrangement came to light. As nothing particularly harmful had been done in the way of treatment no indictment was brought but the coroner severely denounced the "Hall" as a fraud upon the public and announced his intention of reporting it at once to the Medical Council for prosecution.

A curious result of recent "reform" legislation has just been reported. Last July a new Workmans' Compensation Act came into operation, practically compelling employers to fully compensate workmen or their relatives for any injury sustained in their employ. Its first result apparently has been to markedly increase the number of accidents and even of deaths in the occupations covered by it. As compared with the corresponding six months of 1897, there was an increase of twelve per cent. in the deaths and forty-three per cent. in non-fatal accidents. In factories alone the deaths increased from 250 to 350. No rational explanation of these alarming changes seems forthcoming, except that of increased carelessness born of certainty of compensation and pay for lost time, a carelessness which is, of course, most noticeable in slight accidents but which also may lead to serious ones.

Another new disease has just been discovered in the realm of psychiatry. It bears the ponderous name of *morbus eponymicus*, the "naming disease" or as its witty French discoverer calls it, "*syndrome de baptême*," the lunacy of baptism. Its principal symptom is an inveterate desire of naming something after oneself, a disease if possible, but if not, a symptom, a method, even an instrument. It is usually extremely chronic in its course but liable to acute exacerbations at intervals, usually in print.

A partial report has just been published of the work

upon which Professor Kanthack was engaged at the time of his much-lamented death. This was an investigation upon milk as a carrier of tuberculosis, by the ingenious method of inoculating guinea-pigs with doses of the milk itself. The alarming result was obtained that out of thirteen dairies tested the milk of nine caused tubercular developments in the pigs. The sediment obtained by centrifugalization was used for inoculation and the injection proved infective in a number of cases in which no bacilli could be discovered by previous microscopic examination. The reporters think that the test is sufficiently delicate to be of value as a substitute for the use of tuberculin, or at least to be a valuable precedent to this.

A sovereign remedy for baldness has just been made public by a Chinese sage, and that is stewed rats. He is so confident of the beneficial effects of this delicacy upon the glossiness of the pig-tail that he epigrammatically asserts that "a rat is to the human hair what a carrot is to a horse's coat." I fear that most of those who read this revelation will be likely to exclaim "Rats!" in tones of horror—or scepticism, according to their bent, but the proof of the pudding is in the eating, and until this attractive remedy has been thoroughly tried *a la* Brown-Sequards' fluid, cerebrine, *et al*, we have no right to condemn it on *a priori* grounds. Rats are eminently hairy animals and can live to a great age without becoming bald, so why should they not furnish an antialopecic serum or antitoxin of the alleged microbe of baldness?

Another victory has just been scored by the "biologists" in sewage disposal over the chemists. The sanitary authorities of Manchester, after several years' trial of elaborate chemical methods of treating the city sewage, have decided to change to the "soil" or "bacterial" system. No method of treatment has yet been found either so effective, so free from odors, and in the long run, so economical, although the initial cost of the land and its drainage is somewhat heavy. We are so often called upon to denounce and fight against bacteria that it ought to give us peculiar pleasure to recognize their invaluable services to mankind as well.

The building of the new London Polyclinic and Graduates' College is being rapidly fitted up, the resident medical superintendent has taken up his quarters in it, and the clinics and lectures will begin next week.

Medicine is steadily winning recognition as a science and a science of great public value and interest. Dr. Alan Macfadyen, the Director of the Jenner Institute of Preventive Medicine, has been appointed to give a series of lectures upon "Toxins and Antitoxins" in the public winter course at the Royal Institute, in company with such men as Sir Robert Ball, Ray Lankester, and Lord Kelvin.

A curious cause of overpressure has just been brought to light by a public letter of Lord Rothschild. The Jewish children in London are not only keen and industrious pupils in the public schools but are also urged by their parents and rabbi to attend their devotional schools or chedarim for the purpose of religious instruction as well. These are held in the early morning and at night, and as this service of both God and Mammon results in the poor children being in school from 7 *A.M.* to 9 *P.M.*, it is little wonder that complaints of overwork are being heard on all sides. Several prominent Jewish physicians have united in a protest against the senseless system which they declare is already causing physical deterioration in the children, and Baron Rothschild adds his influence to the protest.

It really looks as if London were about to secure an adequate and needed ideal system of water-supply at last. The bitter lesson of last summer and autumn's water-famine has been taken deeply to heart by the London County Council, or "L. C. C." as it is usually styled with American abbreviativeness and negotiations are on foot for the purchase of a whole river valley and water-slopes in the Welsh Mountains, where enormous and practically inexhaustible reservoirs can be constructed whose slopes can be absolutely controlled and protected from all possible pollution.

TRANSACTIONS OF FOREIGN SOCIETIES.

French.

CHOICE OF AN ANTISEPTIC IN CERVICAL DISCHARGE—MODE OF ACTION OF SALINE INJECTIONS IN INFECTIONS—LITTLE TUBERCULOSIS IN THE FRENCH ARMY—URETERO-PYELOSTOMY—ARTERIOSCLEROSIS TREATED BY THYROID EXTRACT—LYMPHATIC TUMORS OF THE SCROTUM CAUSED BY FILARIA—A POINT IN THE SUCCESSFUL CLOSURE OF A FECAL FISTULA—TUBERCULOSIS OF THE TESTICLE—ACUTE LEUCEMIA—AFFECTION OF THE SUPRARENALS NOT ADDISON'S DISEASE—SWEDISH GYMNASTICS IN CONGESTIVE HEADACHE AND INTELLECTUAL FATIGUE.

AT the Therapeutic Society, December 14th, BLONDEL spoke of the choice of an antiseptic to combat cervical discharges. After trying all of the usual substances he became convinced that it is the evacuation of the microbes which is all important, the nature of the fluid employed being of secondary importance. In practice he douches the uterus five minutes or so with a solution of bicarbonate of soda. Then he compresses the cervix between the valves of a speculum, so as to express the secretions of the cervical glands. After that the douche is continued. The evacuation of microbes being thus assured, the excessive uterine discharge is done away with for two or three weeks.

BARDET discussed the mode of action in large injections of saline solutions for relief of infection. All the toxins which develop in the body and affect other organs or tissues may be looked upon as soluble. They may either be diffusible, in which case they do not become attached to the tissues and are easily eliminated, or they may on the contrary adhere to the tissues and modify them more or less profoundly. The favorable action of large saline injections is in part due to the reestablishment of blood tension and in part to the dilution, mobilization, and elimination of the toxins which are non-adherent to the tissues. If the toxins are firmly adherent to the tissues the saline injections have little effect.

BOVET said that saline solution to produce any appre-

ciable elimination of the toxins in severe cases must be administered in large quantities, two quarts or more during twenty-four hours. By increasing the blood pressure and facilitating diuresis the saline injections reestablish the chloruria, and not until then do the general symptoms improve sufficiently to make good the hope of a speedy cure. These results are due to chlorid of sodium, which although not properly speaking a solvent of the toxins, is capable, nevertheless, of producing marked changes in the blood-serum.

KELSCH presented to the Academy of Medicine, December 27th, the results of his experiments with the dust of barracks. He found it difficult to produce tuberculosis in guinea-pigs by injecting the filth from spittoons into their peritoneal cavities. One-third of 122 animals thus treated died of acute infections, some were killed and examined, with a negative result, while the rest remained in perfect health. Of 91 animals inoculated with nasal mucus, only one succumbed to tuberculosis. This mucus came from a cuirassier in apparently perfect health. Either there were no tubercle bacilli in these materials or if present they were not of sufficient power to triumph over an animal belonging to a species peculiarly susceptible to the disease.

DELBET reported the case of a young woman who had suffered from pains in the left lumbar region since the age of eighteen years. Two pregnancies and one miscarriage in the third decade of her life increased her symptoms. When seen by the speaker in her thirty-third year there was a well-marked left hydronephrosis. The right kidney, as shown by catheterization, was normal in action. The left kidney was exposed and found to contain a quantity of odorless fluid, but no calculus. The upper portion of the ureter was the seat of a very tight constriction. It was followed downward by a tedious dissection, opened below the stricture, and proved to be pervious from this point to the bladder by the passage of a probe from above downward. By a ureteropyelostomy an outlet for urine one-third of an inch in diameter was provided. The patient recovered.

LANCEREAUX showed two patients at the meeting of January 3d. One was a young woman who had a generalized arteriosclerosis, and the other a man affected with chronic rheumatism, gout, and arteriosclerosis. These patients had received gradually increasing doses of iodothyrin, beginning with .5 grams (8 grains), and gradually increasing until 3 grams (45 grains), were taken each day. The condition of the woman had improved rapidly, and after four months of treatment her face had resumed its normal aspect, and the trunk, neck, and arms, had become supple so that she could again sew without trouble. The man meanwhile had lost his articular pains, and the osteophytes and the trophic disturbances of the nails had disappeared. There was also less arterial tension, micturition at night had become less frequent, and the urine contained less albumin than formerly. The peripheral arteries had to a certain extent recovered their natural suppleness.

At the Session of January 10th, FRANCK spoke of the dangers attending the administration of extracts of the thyroid gland under conditions in which the gland was normal, for instance, in simple obesity. One ought not to forget that this substance is extremely poisonous, and capable of producing coma, and even death by cardiac collapse. In view of these facts the sale of articles containing thyroid extracts ought to be permitted only upon the order of a physician.

At the Surgical Society, December 21st, LE DENTU spoke of cases of adenolymphocele and lymphadenoma of the groin which could be diagnosed only with difficulty from an omental hernia. He had recently removed lymph varices from the scrotum and had observed a profuse lymphorrhagia to follow. There were filaria in the blood of this patient, as well as in that of the patient who had the inguinal adenolymphocele.

TILLAUX and RECLUS mentioned cases of filariosis of the scrotum simulating hernia which they had treated by ablation of a part of the scrotum, following in so doing the custom in tropical countries. The results were excellent.

At the Session of December 28th, LEJARS showed a girl, aged fourteen years, upon whom many unsuccessful operations had been performed in order to close a fecal fistula of many years' duration. He had finally accomplished this at the second attempt by dissecting out the whole fistulous tract. He found that the artificial anus opened into a large pouch connected with the sigmoid flexure. The opening was closed, and a lateral anastomosis established, the cure being complete. The fecal fistula had been made two days after birth, the child having imperforate anus. Two years later the anus was successfully opened but the fistula persisted as stated.

MONOD related a failure to close permanently a fecal fistula. He attributed his nonsuccess to the incomplete dissection of the fistulous tract.

REYNIER reported a case of tuberculosis of the testis in which the vas deferens was followed up by a reflection of the peritoneum until it could be divided at a distance of only six centimeters (2.5 inches) from the prostate. Its tissue was here unaffected by the disease. Tuberculosis of the testicle has sometimes been unwisely regarded as benign and treated accordingly by imperfect operations. Even in the mildest case the disease may spread to the lungs and cause death. The presence of tuberculosis of the prostate, on the other hand, is no adequate reason for refusing to remove a tubercular testicle, since clinical results show the advantages of such removal and complete cure may take place even though the prostate is involved. From the palliative operations, such as curetting and epididymectomy, Lejars had seen little benefit. The former is readily followed by recurrence and the latter by abscess.

GILBERT and WEIL reported to the Biological Society, December 24th, three cases of acute leucemia, which developed in three months, five weeks, and two weeks respectively. The first of these patients had symptoms similar to those of chronic leucemia, but one of the other two was more like an infectious stomatitis, with spleen and glands enlarged, and the third simulated purpura. In acute leucemia there is an irregularly elevated tempera-

ture with intense anemia and hemorrhages. The onset and course of the disease may be stormy and rapid. In doubtful cases an examination of stained specimens of the blood should always be made. The changes noted by Fraenkel will almost always be found. The red cells have a tendency to assume in a short time the changes of pernicious anemia, and the polynuclear white cells are much reduced in number or altogether absent. The mononuclear white cells, especially the large ones, are increased. They may, indeed, be the only leucocytes which are found in the blood. The eosinophilic cells are not modified.

SERGENT and BERNARD reported that they had attended a man who died with all the signs of acute poisoning. At the autopsy no lesion was found to account for his death, except a complete caseation of both suprarenal capsules. The pathology of these bodies ought to be extended so as to include this and analogous cases which certainly cannot be classed with cases of Addison's disease, in which the chief symptom is melanoderma.

At the Medical Society of the Hospitals, January 6th, MERKLEN presented a man who for some weeks had experienced intolerable pains in the epigastric region in the form of crises which were brought about by the ingestion of the simplest food, or by walking, or even by standing in the erect position. After fourteen-months' treatment, during which time a great number of remedies were employed without the least effect, a laparotomy was performed. There were found many adhesions from the stomach to the anterior abdominal wall, as well as to the neighboring organs. These were all divided except one which extended from the cardiac end of the stomach to the liver. In the middle of the lesser curvature of the stomach there was an induration, which suggested an ulceration. The patient was relieved of his pains by this operation so far as they were caused by peristaltic motions, but they were still produced by walking and by the erect position. A second operation was, therefore, performed, and the ulceration was excised. The pains immediately disappeared and did not recur.

HAYEM said that it is not always safe to make a diagnosis of perigastritis from the continuance of pain as this symptom might be due to the ulcer alone. A more reliable sign seemed to him to be the immobility of the stomach. The normal stomach moves with changes in the amount of its contents, but in perigastritis with adhesions its motions are limited or altogether absent.

MATHIEU said that the diagnosis might be rendered still more difficult by the growth of a cancer in the site of the ulceration. He showed several fragments of cancer tissue which had been expelled with vomited material from a patient who presented all the signs of gastric carcinoma. The microscopic examination of these fragments showed that the tumor was an epithelioma made up of cylindrical cells.

At the Medical and Surgical Society of Bordeaux, December 23d, TISSIE spoke of the value of Swedish gymnastics in congestive headache and intellectual fatigue as experienced by himself while recently in Sweden on a Government errand. One of the characteristics of the Swedish massage, is the application of the treatment at the terminations of the nerves affected, *e.g.*, the supra-orbital or infra-orbital. Vibrations, either made with the hands or with a mechanical vibrator, are usually employed, and have a sedatory influence. They are accompanied by massage of the muscles which terminate in the vicinity of the nerve endings. The length of the treatment depends on the condition of the patient. Tissie made a distinction between those patients whose recuperative powers are good, and those who are neurasthenic and have inherited fatigue. In both classes of patients, the treatment produces repose but in the former class the repose is followed by a speedy reparation of the vital forces, which in the latter class takes place slowly. The massage is preceded and followed by movements, chiefly respiratory, which are designed to relieve cerebral congestion. He adapted this treatment in his own practice and was gratified by the good results which he obtained.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.—SECTION ON SURGERY.

Stated Meeting, Held Monday, January 9, 1899.

W. W. VAN ARSDALE, M.D., in the Chair.

GENERAL PERITONITIS TREATED BY ENTEROTOMY.

DR. H. LILIENTHAL: I have two patients here this evening who illustrate a method which I have been employing in the treatment of general peritonitis accompanied by great distention. The distention in general peritonitis is a symptom which causes very great discomfort on account of its mechanical effect upon respiration and the obstination to which it gives rise, and it is also attended by danger and may indirectly be the cause of death. For these reasons it is imperative that it should be relieved, and it seems to me that this is best done by opening the intestine by incision, in order to evacuate the gas and septic fluid. Puncture alone is not likely to be followed by success. A longitudinal incision should be made in the gut at a point furthest away from the mesentery, and the patient should then be turned a little on the side in order that gravity may assist in forcing out the gas and septic contents of the gut. The incision is then closed by sutures of fine silk and another coil of intestine pulled out of the wound and treated in the same way. This should be repeated until the gut is perfectly flaccid.

This boy is eight years of age and was admitted to the hospital July 23, 1898. Although he had been ill but four days he was profoundly septic, and in a semicomatose condition. The abdomen was greatly distended, was painful on pressure, particularly on the right side, and the pupils were dilated. There had been no movement of the bowels in two days in spite of the admistration of castor-oil and similar household remedies. The prognosis seemed very bad indeed. I first saw him at eight o'clock in the evening, and I operated upon him before midnight. A large quantity of foul-smelling serum was found in the abdominal cavity, and there were many

adhesions about the appendix. The latter, which appeared to be gangrenous, was removed, and the adhesions broken up. The boy's condition was so low that it was feared he would die upon the table, but it was thought best to prolong the operation in order to relieve the distention and thus give a better chance for recovery. Therefore, the three incisions were made in the bowel, a large quantity of gas and fluid escaped, and the incisions were closed with two or three silk sutures. A drain, such as is recommended by Dr. Morris, consisting of gauze surrounded by rubber tissue, was then carried down into the pelvis and allowed to protrude through the abdominal wound, which was held open by superficial gauze dressing. This drain was removed on the third day, and replaced by a filament of gauze. Secondary suture was performed two weeks after the operation. It is interesting to note that cultures taken from the appendix and from the fluid which escaped upon opening the abdomen were found to contain colon bacilli only.

I performed the same operation upon this man on May 5, 1898. His condition at that time was extremely bad although he had been sick but two days. His pulse was small and irregular, there was constant vomiting, and he presented the typical picture of acute sepsis. The abdomen was extremely tympanitic, palpation caused great pain, and there was edema of the abdominal wall at all points. Upon opening the abdomen a large quantity of seropurulent fluid escaped. A very large and gangrenous appendix was removed and the intestines were opened by four incisions. Recovery was uneventful. Cultures taken from the appendix showed the colon bacillus only, but those taken from the pelvic cavity showed, in addition, the micrococcus pyogenes albus.

DR. R. H. M. DAWBARN: I would like to ask Dr. Lilienthal whether, in his judgment, benefit would be derived from injecting into the bowel a saturated solution of Epsom salts, as suggested by Dr. McCosh, in cases of paralysis and distention of the bowel. I would also like to ask if any of the gentlemen present have had any experience with the subcutaneous injection of Epsom salts as a means of causing a movement of the bowels.

DR. R. T. MORRIS: I have practised incision of the bowel but so far have made but a single opening. I think, however, that recovery would have been more rapid in some of my cases had I made several incisions. The gas does not always escape as freely as one would expect when the gut is incised, and I have gone so far as to stitch the ileum to the abdominal wall, thereby risking the danger of a bad angle later on in order that the gas might escape during the day and night following the incision of the intestine with the expectation of closing the fistula later which, however, was not necessary as it closed spontaneously. Of late years I have been making my abdominal incision smaller and smaller, and now rarely make one longer than three inches. I do not leave the wound open, but close it carefully, layer by layer.

I would like to hear more about injecting Epsom salts. I have always considered that the reason for administering this drug is because of its hydroscopic nature, which causes a rapid exosmosis of serum and toxin-bearing fluids from the infiltrated tissues into the bowel from whence they are discharged. If this is not the whole *rationale* of it, I would like to know it.

I would like to mention a little procedure which Dr. Lilienthal may find of service in these cases, and that is stretching of the sphincter ani. Patients with general peritonitis have great difficulty in emptying the bowel even after a large injection. This will be more easily accomplished after dilatation of the sphincter muscle.

DR. JOHN A. WYETH: The treatment by incision into a bowel which is paralyzed as a result of septic peritonitis is so logical that it is strange that it is not more generally employed. It has occasionally been practised by individuals in this city during the last ten years but has never become popular. Paralysis of the bowel, it seems to me, is due to two causes; one external, and the other internal, both of which are the result of the peritonitis. The first is the plastic lymph which is rapidly deposited upon the external wall of the intestines; the other is the hyperdistention within the bowel due to an accumulation of gas or fluid. The latter is relieved by multiple incision of the gut. My experience has taught me that a single incision does very little good.

DR. FREDERICK LANGE: This subject is of so much importance that I do not think we should arrive at conclusions too hastily. In the first place, no proof has been submitted to show that the two patients presented this evening really had general peritonitis, or that they were septic. Nothing has been said about the pulse and temperature, and there is nothing in the history of the cases which would lead one to consider them cases of general peritonitis. I inferred from Dr. Lilienthal's remarks that he would have us believe that a collapsed gut will absorb less than a distended gut. Theoretically, I do not think this is the case. The subject is interesting, however, and opens up a new field for experimental investigation. My experience in the treatment of general peritonitis has been very discouraging. I have had patients suffering from extensive pelvic suppuration whom I have treated by operation and a limited number have recovered. I am not prepared to say that the peritonitis was general, that it extended to the diaphragm and on the upper surface of the liver. A septic peritonitis which is confined to a limited area will sometimes give rise to the most severe symptoms, and may even cause death. Much, too, depends upon the nature of the infecting poison. Personally, I have not had good results from incision of the bowel for the relief of distention in general peritonitis.

DR. CARL BECK: My views are similar to those of the last speaker. I think that all cases in which recovery is said to have followed general peritonitis were really cases of circumscribed peritonitis. In regard to the operation under discussion I might say that I am in favor of a single incision.

DR. A. E. GALLANT: I think the term intestinal paresis is a misnomer when applied to these cases. I once saw a post-operative case in which there was so much distention that the woman's waist, which originally measured twenty inches, measured forty-eight; the abdominal wall was so thin that it was possible to see the

peristaltic action of the bowels, therefore, it is wrong to call such a condition a paralysis of the intestine. The distention in this case was relieved by simply rubbing the abdomen in the manner described by me some five years ago.

DR. DAWBARN: Dr. Morris has spoken of the prevailing tendency to make the abdominal incision smaller than was formerly done. In this connection I cannot deprecate too strongly the custom of making a large incision in cases of general peritonitis for the purpose of turning the intestines out of the abdomen and irrigating the cavity. It is impossible to remove every bit of pus from the abdominal cavity by irrigation. To prove this to my own satisfaction I poured a gobletful of milk into the pelvic cavity of a cadaver, then irrigated the cavity until the water returned perfectly clear, and sponged it out dry, yet, when the abdomen was opened several drams of milk were found among the folds of the mesentery. On another occasion I repeated the experiment, using pus instead of milk.

DR. W. W. VAN ARSDALE: I have devoted considerable thought to this subject and I think there are some points connected with it which have not been mentioned. Further studies should be made in regard to absorption in the abdominal cavity. There seems to be no doubt that the absorption which causes most danger to life is that which goes on in the center of the diaphragm and above the liver. If the peritonitis reaches this point there is no way of saving life. If other portions of the abdominal contents are the seat of the inflammation a cure can be effected. If the peritonitis is of the fibrinous kind there is more hope for the patient. If the intestines are distended by general paresis there is less space in the abdomen and, consequently, more pressure; moreover, fluids run up under the diaphragm and spread infection. If we reduce this distention by opening the intestine the result will be more space, less pressure, and less absorption. By keeping the wound in the intestine open continuous drainage may be secured which changes the current of lymph and has a beneficial effect. I have lately been pursuing this method.

In regard to the objection raised against incision of the intestine, to the effect that it is difficult to thoroughly empty the bowel even after incision is made, this will be facilitated by saline irrigation of the bowel at the time of the operation. The procedure is undoubtedly of value and should be more generally employed. A systematic application of the principles involved will throw additional light upon the subject.

DR. LILIENTHAL, in closing: In regard to Dr. Dawbarn's remarks concerning irrigation of the abdominal cavity I agree with him that it is not possible to thoroughly cleanse it and I do not think it should be attempted.

Stretching of the sphincter ani was referred to by Dr. Morris. In my cases I have introduced a rectal tube which has been left in for hours at a time and which answers the purpose even better than stretching the anus.

As to whether the cases reported were or were not cases of general peritonitis, of course I do not know whether every square millimeter of the peritoneum was affected, nor do I care, but I do know that the patients were suffering from what is known as general peritonitis, so far as it is possible to make that diagnosis without an autopsy. I am sure that Dr. Lange would have made the same diagnosis had he seen the patients both before and at the time of operation.

I have never used Epsom salts in these cases. If the effect of this drug is merely hydroscopic, I would suggest that glycerin would act as well.

TWO UNUSUAL CASES OF ANEURISM.

DR. CARL BECK: This is a case of aortic aneurism. The patient is thirty-nine years of age, German by birth, and gives the following history: His father died suddenly at the age of sixty-five years; his mother also died suddenly at the age of sixty. He denies syphilis, and examination shows no evidences of the disease. There is no history of gout or chronic nephritis. He states that about five years ago, while lifting a heavy weight, he felt pain in the left side of the neck, and a small protuberance appeared there. He entered a hospital and was treated for torticollis, and eighteen months ago returned to the hospital to be treated for malarial fever. At this time the tumor was not larger than a good-sized apple. On September 21, 1898, when the patient was admitted to St. Mark's Hospital, the transverse diameter of the tumor was 7½ inches, and it was found that the sternum had almost entirely disappeared as a result of pressure, as shown in these skiagrams. In spite of the enormous size of the tumor at the present time there is but little pulsation to be felt. This is probably due to the fact that the aneurismal sac is filled with fibrinous clots. Resonance is very marked. It is also interesting to note that the radial pulse on the right side is a little stronger than that on the left. The patient's lungs are normal. Following the advice of the French physicians, we have been giving this man large doses of gelatin, which has a tendency to coagulate the blood, and it would seem that the tumor is becoming smaller and harder. The condition of the patient is remarkable; he goes about and attends to his business just as if he did not have an aortic aneurism, and his hoarseness, which was due to pressure paralysis, has almost entirely disappeared.

I regret that I am unable to show you the patient from whom I removed this specimen, but he is confined to his bed by an attack of pneumonia which is probaly due to embolism. Four weeks ago I removed this femoral aneurism from a man sixty-nine years of age. It is of the fibrinous class and shows very clearly the circulatory canals. The patient states that three years ago he received a slight injury of the thigh, but paid little attention to it. It caused him no trouble until three months ago when he noticed a tumor the size of a lemon at about the middle of the thigh at the point of injury. The tumor increased rapidly in size and as there was slight fluctuation it was thought to be an abscess and incision was seriously considered. Fortunately, this was not attempted. When I saw the patient, five weeks ago, I found a large umor of an ovoid shape extending from the internal con-

dyle of the femur to the groin. It was very hard and no fluctuation could be detected. The leg and foot were absolutely normal. At first I thought it was an osteosarcoma, its hardness, slow growth, and immobility being in favor of that assumption. Two exploratory incisions were made and the tumor found to contain blood, examination of which showed an abundance of leucocytes. A skiagram showed the femur to be normal, therefore osteosarcoma was eliminated. The tumor was then thought to be a sarcoma of the sheath of the femoral vein and operation was undertaken. A gush of blood followed division of the tissues and examination showed the abnormality to be an aneurism in the internal fossa. Forcible pressure was made to control hemorrhage until the femoral artery was ligated at Scarpa's triangle. The sac was then dissected out with ease.

DR. WYETH: The cases are very interesting to me because of the fact that I have devoted so much time to the study of aneurism. I would suggest that in the future management of the first case a method be employed which I have tried in a case of this kind which was near the breaking-point, the aneurism having eaten its way through the thoracic wall. I boiled a lot of silver harelip pins and thrust them into the aneurism as if it were a pin-cushion, employing twenty or thirty of them and leaving them in the tumor eighteen hours. This procedure was repeated, the pins being left in thirty-six hours, and the result was that there was a perceptible effect in the way of thickening of the sac-wall. Under this mechanical effect the patient improved rapidly and the tumor went down to the level of the chest-wall. The man died two years later as a result of cerebral apoplexy. I think Dr. Beck would be justified in employing this method in his case as the tumor seems to be on the point of breaking through.

DR. DAWBARN: I had the pleasure of assisting Dr. Wyeth in the case to which he has referred. The method employed was suggested by McEwen of Glasgow. I think that in the case under discussion Dr. Beck should resort to either this procedure or to that which consists of introducing into the aneurism one or two meters of very fine piano-wire in such a manner that it will recoil upon itself in the sac, and passing through it a galvanic current, the positive pole being directed to the interior of the aneurism and the negative to the patient's back. The application should last half an hour and the end of the wire should then be tucked into the sac and left there. The administration of gelatin should be continued and I would suggest that large doses of iodid of potassium be added to the treatment.

DR. BECK: We have been giving the patient gelatin during the past six weeks, apparently with good results and it will be continued. I am very grateful for the suggestions which have been offered and later on will employ the method referred to by Dr. Wyeth; whose skill in the treatment of these cases is so well known.

DR. E. M. FOOTE then read the paper of the evening:

INGROWING TOE-NAIL; A COMPARISON OF METHODS OF OPERATION.

(see page 200)

DR. CHARLES N. DOWD: The author should be congratulated upon having devised a method which promises well. It is a modification of the operation of Anger, the essential feature of which is the removal of the matrix. This operator did not use cocain, and was, therefore, obliged to work very rapidly and imperfectly, so that his method has been improved by the surgeons who have modified it. I have been performing an operation which differs very little from that suggested in the paper, except that it takes away a little more of the tissue. I have not seen the deformity he refers to as a result of removing too much of the toe, but I am inclined to think his method the better one. It certainly removes the matrix of the nail and this is the essential principle. It should be dissected away almost down to the bone, and if this is done one can be sure there will be no recurrence. It is moreover a most simple method.

DR. ERDMANN: I have been employing a method very similar to the one described by the author, but during the last three years I have omitted the sutures, merely bandaging the toe when applying the dressing, and have not seen any trouble follow this simplification of the operation.

DR. DAWBARN: During the last ten years I have been performing a little operation which has proved so satisfactory to me that I have ceased to experiment with other methods. I make two incisions, which form flaps and, after removing the ulcerated and septic tissue, these are brought together and held in place by one silkworm-gut suture which extends across the nail and is removed on the tenth day. The important point is to remove the root of the nail. I have demonstrated the fact that it extends to within one-tenth of an inch of the joint. I remove but a very narrow strip of the nail—not more than one-tenth of it.

DR. TOUSEY: I have operated in at least three hundred cases of ingrowing toe-nail and have successfully employed a modification of an operation, a description of which I published some years ago. I do not use hemostatic forceps, but a very firm bandage. On the second day after the operation I soak the bandaged toe for half an hour to loosen the iodoform-gauze packing in the wound and then apply a Thiersch graft taken from the arm. I never take a graft from the leg, especially if the patient is a woman, for I regard all women as possible candidates for ulcer of the leg. I think surgeons should be warned against taking away too little tissue. Nor does it seem to me essential to make the nail narrow.

DR. W. W. VAN ARSDALE: I will admit that I have had trouble in operating in these cases but it has been because it is difficult to do any plastic work in dispensary practice in which these patients are usually seen. It is impossible to keep them off their feet during the process of healing. I have derived the most satisfaction from an operation which, I believe, is to be attributed to Hamilton and which I first saw performed by Dr. Wyeth. It consists in removing the entire matrix, scraping the periosteum from the bone, and closing the flaps made by the incision. All operators agree that the entire matrix should be removed in order to make the operation suc-

cessful. In the past it was my habit to remove one-half of the nail, but I found that within six months the patient would come back with ingrowing toe-nail on the other side.

DR. FOOTE, in closing: I hesitate to say that this operation was never performed before I did it, because so many operations have been devised for the cure of ingrowing toe-nail that one cannot be familiar with them all. In regard to the distance of the matrix from the joint, this was stated in the paper as being one-fourth of an inch. As to a narrow nail causing as much trouble as a wide one, the width of the nail is not a factor in giving rise to this deformity. The curve of the nail is the cause of the trouble.

REVIEWS.

ON CARDIAC FAILURE AND ITS TREATMENT; with Especial Reference to the Use of Baths and Exercise. By ALEXANDER MORISON, M.D., F.R.C.P., London: The Rebman Publishing Company, Ltd., 1898.

THIS book is well worth careful perusal. It is a serious endeavor to consider the treatment of chronic cardiac affections on scientific principles.

The book is divided into four parts; the first deals with the diagnosis and symptomatology of cardiac failure; the second considers the neuromuscular and hemic factors in disease of the heart and their bearing upon prognosis and treatment; the third deals with the general treatment of cardiac failure, and the fourth with the treatment by baths and exercise. A valuable appendix by Dr. Groedel of Bad Nauheim on the baths and exercises there employed completes the work.

Each division is carefully and studiously considered and perhaps with more detail than is necessary for a work of this character. This, of course, is not a fault, but, as the work will be read by trained physicians, it compels them to go over a mass of elementary material which should be relegated to works on physiology and physical diagnosis.

It seems to the reviewer that too much importance is placed on the use of the sphygmograms in the diagnosis of various intracardiac conditions. It is fairly well known that various sphygmograms may be obtained even with most accurate and reliable sphygmographs from the same case of cardiac disease within the space of a few minutes. It would, therefore, be unsafe to predict from sphygmographic tracings with any degree of assurance the character of the changes which the heart might undergo during treatment.

There can be no doubt that the chapters devoted to the general balneological and gymnastic treatment are deserving of all praise, containing as they do one of the best reviews of these subjects in the English language.

A CLINICAL MANUAL OF SKIN DISEASES. By W. A. HARDAWAY, A.M., M.D. Second edition. Philadelphia and New York: Lea Brothers & Co., 1898.

IN this new edition of Dr. Hardaway's book the text is completely rearranged and to a large extent entirely rewritten. The reader's admiration will be evoked by the skill with which the author has condensed within comparatively narrow limits so complete an account of the science of dermatology not less than by the impartial character of his judgment in all matters of controversy and by the thoroughly scientific spirit that pervades the whole work.

In estimating the value of a text-book on skin diseases the dermatologist will turn naturally to the chapter on eczema. A perusal of the seventy pages devoted to this subject in Dr. Hardaway's book will leave little to criticise and much to praise. That the book is thoroughly up to date may be inferred from the fact that even such recent subjects as Rixford and Gilchrist's remarkable cases of protozoon infection of the skin and Pollitzer's interesting views on xanthoma are sufficiently discussed. We congratulate the author on the marked success he has achieved and bespeak for the book the recognition which it merits.

THERAPEUTIC HINTS.

For Scrotal Pruritus.—

℞	Ac. carbolici	ʒ v
	Spts. rect.	ʒ vi
	Glycerini	℥ iiiss
	Aquæ	℥ x.

M. Sig. Mix one to four tablespoonfuls in a glass of hot water and use to bathe affected parts several times a day. In addition, sulphate of quinin and bicarbonate of soda are recommended for internal treatment.—*Brocq.*

For Essential Pruritus.—

℞	Ammonii valerianat.	gr. xv
	Syr. simplicis	ʒ v
	Aq. menthæ piper.	℥ iv.

M. Sig. Two to four teaspoonfuls daily.

For Ovarian Neuralgia.—

℞	Ext. belladonnæ	gr. iv
	Ext. stramonii	gr. v
	Lactophenin	ʒ iss.

M. Ft. pil. No. XX. Sig. Two or three pills a day. —*Martin.*

Application for Fissure of the Tongue.—

℞	Ac. carbolici	*m.* xii
	Tinct. iodi	*m.* xl
	Glycerini	ʒ ii.

M. Sig. External use.

For Painful Burns, Fissures, or Ulcers.—

℞	Orthoform	ʒ ss– ʒ i.
	Vaselini	gr. lxxx
	Lanolini	℥ ss.

M. Ft. unguentum. Sig. External use.

For Impetigo.—SABOURAUD recommends a camphorated solution of sulphate of copper and sulphate of zinc (1–100 or 1–200) applied continually by means of compresses, as the most effective treatment.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIV. NEW YORK, SATURDAY, FEBRUARY 25, 1899. NO. 8.

ORIGINAL ARTICLES.

THE PROBLEM OF TYPHOID FEVER IN THE UNITED STATES.[1]

BY WILLIAM OSLER, M.D.,
OF BALTIMORE, MD.;
PROFESSOR OF MEDICINE IN THE JOHNS HOPKINS UNIVERSITY.

WHAT I am about to say on the subject of typhoid fever may appear to many of you trite and stale; and so indeed it is, but under the circumstances the very staleness is a warrant for repetition; the triteness makes earnest reiteration a necessity. Nor do I forget that only two years ago a most interesting discussion on typhoid fever was held under the auspices of this society, a discussion which brought out many important practical points. Since then the country has had a very bitter lesson—not a more bitter one than it has had year by year as each autumn recurs, but the method of application coming as a sad conclusion to a brilliant military victory aroused a degree of public feeling which may be taken as an augury of hope.

For three generations the physicians of the country have been studying the problems of the continued autumnal fever. No other disease has possessed such a perennial interest; of no other acute disease can we read so full a history from American sources alone. With no other disease are associated the names of men still honored as our great leaders. The physicians of the first generation, to 1830, lived in a period of transition, when old theoretic conceptions were giving way to proper methods of observation. It is particularly interesting to see typhoid fever as depicted by one of the best of them, by one who in thirty-five years practised medicine extensively in every New England State but Rhode Island. I reread at intervals Nathan Smith's "Practical Essay on Typhous Fever," published in 1824, each time with increasing respect for his sagacity. There is more strong sane sense in his booklet of eighty-five pages than in anything that had appeared on "the slow nervous fever" since Huxham. It is most refreshing to turn from contemporary treatises on fever in English, French, and German to this clinical masterpiece. Happy the patients who fell into the hands of the old founder of Dartmouth Medical School and the first Professor of Medicine at Yale! With but little modification his section on treatment might be transferred to one of our year-books as the freshest and the best.

The men of the second generation did notable work in bringing new methods of observation and in clearly outlining the differences between typhus and typhoid fever. They came to the problem splendidly equipped, inspired by their great teacher, Louis, whose practical mind appealed with peculiar force to the young Americans who studied with him between 1828 and 1845. Among them, Elisha Bartlett, James Jackson, Jr., W. W. Gerhard, George B. Shattuck, and Alfred Stillé were chiefly instrumental in promoting in this country the study of fever. To appreciate their position one has but to read W. W. Gerhard's masterly contributions, and Bartlett on "Typhus and Typhoid Fevers," the first edition of which was published in 1842, a treatise which might be put into the hands of a student today for the main features of the morbid anatomy and symptoms of these diseases. The contrast between the modern stand taken at that date by leaders of medical thought in this country and in Europe, particularly in England, is shown by the fact that Sir William Jenner, recently dead, had to attack the problem anew in 1849–50, before English physicians could be convinced of the essential distinctions between typhoid and typhus fever. In acknowledging the work of others he particularly mentions the names of Gerhard, Shattuck, and Bartlett as men who had already done what he was about to attempt. And I should like to remind you that one of the best contributions to the subject, Austin Flint's "Clinical Reports on Continued Fever" was the outcome of a committee appointed by this society nearly fifty years ago.

I shall not allude to the labors of the men of our own generation. The care and zeal with which typhoid fever has been studied during the past thirty years by the physicians of this country has been beyond all praise. I wish to emphasize as strongly as it is possible to do in words, that we as a profession have been persistently alive to its importance. This I feel is important to affirm as I heard the suggestion from a lay quarter that perhaps if we had studied the disease more thoroughly there would be less of it in the country.

To bring into stronger relief the contrast which I wish to draw, bear with me for a few minutes while I review a few familiar points. One of the great

[1] An address delivered before the Medical Society of the State of New York at Albany, February 1, 1899.

facts in the history of the past half century has been the remarkable increase in our knowledge of the infectious diseases. In any general survey of this group there is, perhaps, no single member of it upon which we physicians can dwell with greater pride and satisfaction than upon typhoid fever. In every relation the growth of our knowledge has been extraordinary. The etiology has been so worked out as to justify the hope that the remaining gaps will soon be filled. Think for a moment of the laboratory work of the past twenty-five years! Our position to-day is the result of the combined labors of thousands of workers in Europe and in this country—labors carried out with a devotion and zeal for which we general practitioners (I say nothing of the public) are not always properly appreciative.

I need not dwell upon any special points in the morbid anatomy, or indeed upon the symptomatology, in both of which we have progressed chiefly in a very much wider recognition of the clinical and anatomical features of the disease.

The diagnosis has been simplified partly by the accurate differentiation of it from typhus fever (which has almost totally disappeared), partly by the discovery of the parasite of malarial fever, but still more by the grouping of well-recognized symptoms, and by certain special methods for the detection of the bacilli or of the reaction of their products.

And most important of all for the individual patient our enlightenment on the question of treatment has been full, I will not say conclusive, in all directions. Nursing and diet are universally recognized as the most essential elements, and we have abandoned, in great part at least, the active measures of our grandfathers, bleeding, vomiting, and purging. The death-rate has been lowered eight or ten per cent. It is not an easy matter, however, to get the average physician out of the drug habit in typhoid fever. The words of the wise old man, Nathan Smith, should still carry weight: "It does not follow, of course, that the disease in all cases requires remedies, or that a patient should necessarily take medicine because he has the disease."

But these advances, as we call them, sink into insignificance before the triumphs of sanitation in the prevention of the disease. Sixty years of sanitary reform have swept away typhus and cholera and have restricted yellow fever within narrow areas; we have learned how to fight tuberculosis and diphtheria, and in a hundred other ways the prevalence of the infectious disorders has been lessened. One demonstration stands out in clear relief above all others—*with a clean soil and pure water typhoid fever disappears.* In cities which stood at the head of the list in mortality from the disease, as Munich and Vienna, the death-rate has dropped to the lowest known percentage after the introduction of drainage and a good water-supply. The object lesson of some of the Continental cities has been paralleled in a few—but far too few—of the cities of this country. Figures in illustration and black diagrams have done duty at our societies until many of the members squirm at the very name of Munich. That imperfect drainage and a polluted water-supply mean a high mortality-rate from typhoid fever is the very alphabet of sanitary science. In scores of instances carelessness in one or other of these points has led to widespread epidemics; incessant vigilance is universally recognized as the price of safety. I need not dwell further upon this aspect of the question, but I repeat, Mr. President, that we can point with justifiable pride to typhoid fever as the best understood, the most carefully studied of the acute infections, the one most directly under our control, the one in which the greatest victories of hygiene have been won.

Let us turn from this picture with its glowing colors to a more somber canvas. Last autumn this nation in the moment of victory had a rude awakening, a sudden conviction, a hard lesson. A voice like that heard in Ramah went up throughout the land—"lamentation and weeping and great mourning." From Montauk Point to San Francisco, from Minneapolis to Tampa, Rachels were weeping for their lads cut off by a cruel disease. The most bloodless campaign in history was followed by a relatively greater mortality from disease than in any recent war, and chiefly from this very disease over which I have been chanting the peans of the triumph of our profession. To us these autumnal dirges rang no new tune; we had heard the same in the palace of the rich, in the crowded tenement, in the hospital ward, in peaceful New England valleys, in the settler's shanty of the far West, in the lumberman's shack, in the mining camp. Year by year we had listened to the Rachels of this land weeping for their fair sons and fairer daughters, not killed by any pestilence that walked in darkness, but by a preventable sickness that destroyed in the noon-day—the noon-day of the intelligence of a civilized people. People asked each other what it all meant. Nothing more than a slight extension of the judgment upon criminal neglect of sanitary laws. The number of soldiers who died of typhoid fever during and after the war was a bagatelle in comparison with the total annual deaths from the disease in this typhoid-stricken country. Throughout the length and breadth of the land typhoid fever prevails so extensively in township and county, in village and city,

that any large body of men aggregated together is almost certain to become infected.

This is a nation of contradictions and parodoxes. A clean people, by whom personal hygiene is carefully cultivated, displays in matters of public sanitation a carelessness which is simply criminal. A sensible people, among whom education is more widely diffused than in any other country in the world, supinely acquiesces in conditions shameful beyond expression. I do not propose to weary you with statistics, of which our journals and reports are full, but I will refer to a few facts drawn at random from three cities and three States, illustrating this shocking neglect.

Philadelphia, the most typical American city of the Union, presents to-day a state of appalling apathy. For years the diluted sewage of the Schuylkill Valley has furnished drink to its best citizens, who bathe for many days of the year in water resembling a thin pea-soup. Individually the Philadelphian seems to be—nay, he is—an intelligent being, who deplores sincerely this condition. Collectively such a community must be regarded as lacking in one of the most essential features of civilization. Last week (ending January 28th) there were 40 deaths from typhoid fever in the city, and 420 cases reported! Last year it is estimated that there were between 5000 and 6000 cases of typhoid fever, 600+ of which were fatal. A writer in the *Philadelphia Medical Journal* last week estimates the money loss from this disease at a million and a half dollars.

In Baltimore we are a little better off, though typhoid fever prevails extensively, and more than two hundred people die of it annually. The city is unsewered, has more than 80,000 cess-pools, and has a water-supply with unprotected sources. With proper sanitary measures the present death-rate of between 40 and 50 per 100,000 of the population should fall to 10 or 12.

The condition of the National Capital is an excellent sanitary index of the whole country, and illustrates, too, how persistently those in power neglect the repeated warnings of the medical profession. One might have supposed that in Washington, governed by a commission under direct control of the central government, and to a large extent free from the influence of politics, sanitary measures, which are everywhere recognized as essential, would be carried out. For years the Medical Society of the District of Columbia has agitated the subject, and committees have urged upon the commissioners certain much-needed reforms, particularly relating to the purification of the Potomac water, which is practically the only source of supply. A committee, of which Dr. George W. Johnson was chairman, reported recently that for the past seventeen years there has been an annual average of nearly 1500 cases of typhoid fever.

Dr. Smart of the Army, a leading expert on sanitation, expressed the plain truth when he said the other day, that *in the matter of the purification of the water-supply of her large cities, the United States is a generation behind Europe.* Serious as is this condition in so many of the large cities of the Union, it is not, in reality, so dangerous as the widespread extension of the disease throughout the smaller towns and country districts. The last reports of three important States illustrate this. We gather from the "Report of the Board of Health of the State of Indiana" that of the ninety-two counties typhoid fever prevailed in all but ten, and from some of these there were no reports. A total of 655 persons died in the counties of the State from typhoid fever during the year ending September, 1897.

In your own State the last annual report issued (1897) gives the total number of deaths from typhoid fever as 1585+, to which must be added a very large proportion, at least, of the deaths recorded as due to the malarial fevers. If we allow, say, 38 deaths from the various forms of malarial infection in New York State, which I put as a very large figure for the year, this brings the total mortality from typhoid fever to 2000+. It is interesting to note, as bearing out what I said in connection with the wide extent of the disease in the country and smaller towns, that those districts of the State with a percentage of city population under 50 per cent. have a relatively greater death-rate. The maritime district, for example, with 90 per cent. of city population, has a death-rate of only 16+ per 100,000 of population, while the Hudson Valley, with only 40 per cent. of city population, has 37+; and the Mohawk Valley and the southern tier of counties, with 31 and 30 per cent. respectively of city population, figure with 34+ and 37 deaths per 100,000 of population.

In the organized study of sanitation Michigan is one of the model States of the Union. Dr. Baker's reports upon the prevalence of typhoid fever are of particular interest. In his last, 1897, it is stated that there were in Michigan 642 separate outbreaks of the disease, with 774 deaths, a rate of 23+ per 100,000 living. There were only three counties from which the disease was not reported. It is gratifying, however, to note the gradual reduction of the death-rate from typhoid fever in the State during the twenty-nine years available for statistical data. While still far too high, the persistent efforts of the State Board of Health are gradually limiting the ravages of the disease.

Mr. President, the problem of typhoid fever, no

longer in our hands, has become a question of grave public concern. What more can we, as a profession, do? From the text *Salus populi suprema est lex*, in season and out of season, we have preached sermons which fill huge volumes of State reports, and as regards typhoid fever, we have preached in vain. Perhaps not wholly in vain, since in many cities, as in Boston, in many States, as in Massachusetts and Michigan, the incidence of the disease has lessened materially; but the existing conditions are proof that we have failed to bring conviction home to the minds of the people. An incidental advantage of the late war was the direction of public attention to the widespread prevalence of the disease, but it is doubtful if the lesson was bitter enough to enforce at once the teaching that matters of health come within the province of practical politics. It may seem a hard saying, but for the sake of prospective victims in the years to come, let us hope that the deaths from typhoid fever this year in Philadelphia may reach 1000, and the number of cases 10,000. *Then* the citizens of that town will stop drinking sewage, and will soon be able to wash in clean water. Great epidemics are the only great reformers, but, except in limited areas, typhoid fever rarely now assumes pandemic proportions. Quite as impressive, though more difficult to teach, is the lesson of its disappearance in large towns previously hot-beds of infection by attention to ordinary sanitary laws.

The solution of the problem is easy. What has been done in many parts of Europe can be done here; the practical conviction of the people is all that is necessary. Upon them is the responsibility. Let us, meanwhile, neither scold nor despair. The good-natured citizens who make up our clientele, pay our bills, and vote the straight party ticket have but little appreciation of scientific questions, and are led as easily (more easily) by a Perkins or a Munyon than by a Lister or a Koch. Under the circumstances it is marvelous that so much has been achieved in fifty years. "The larger sympathy of man to man" which we physicians are called upon to exercise daily in our calling, demands that we continue our efforts—efforts often fruitless in results, but very helpful to ourselves—to educate this foolish public. What is needed seems so easy of accomplishment—the gain would be so enormous! We ask so little—the corresponding benefits are so great! We only demand that the people of this country shall do what Elisha asked of Naaman the Syrian—that they shall wash and be clean—that they shall scour the soil on which they live, and cleanse the water which they drink.

The problem will be solved when, first, *every city in the Union has a supply of pure water (including ice), and is properly drained;* secondly, *when suburban and rural hygiene are systematically organized.* In many ways a city's danger is from the country. Infected milk, infected ice, infected oysters, and dirty health-resorts account for a considerable percentage of the cases treated in the towns. Many of the State Boards of Health need a more efficient organization; all need a larger annual appropriation. A bureau of public health should form an integral department of each State government, with which civic, county, township, town, and village boards should be in close organic affiliation. The salaries of the health officers should be changed from the beggarly pittance, almost the rule, to sums which would warrant a demand on the part of the public that such officials should have modern training in sanitary science. Special courses should be offered in the medical schools, as is done in England, or even diplomas given. All this will come when the health of the people is made a question of public, not party, policy. It is encouraging to note that such States as, for example, Massachusetts and Michigan, in which the health boards have the most efficient organization, are those in which the death-rate from typhoid fever has been progressively diminishing.

The responsibility for the widespread prevalence of the disease rests directly upon the wanton carelessness of the people. God's own country, with man's own backyard, and the devil's own cesspools expresses the existing conditions. A threefold duty devolves upon the members of our profession: First, to preach cleanliness! cleanliness!! cleanliness!!!; secondly, to give a loyal and willing support to the State health officials; and, thirdly, to guard every case of typhoid fever as a center and possible source of further infection.

Let us hope, Mr. President, that the lesson of last autumn has been taken to heart by the citizens of this land. Sometimes from our desolation only does a better life begin. Surely, the blood penalty has been paid in full for the gross neglect of sanitary laws. The wantonness of the sacrifice is so terrible, so inhuman. Nature is inexorable and, red in tooth and claw with ravin, knows nothing of our humanitarian care of the individual. But her sacrifice is never wanton. Careful of the type, careless of the single life, sacrifice is a law of being, a condition of existence. In one of his delightful lectures on the "Foundations of Zoology," Professor Brooks tells us that of the countless millions of the king of fish which yearly enter the Columbia River seeking the breeding grounds, in the stern impulse of propagation, none return. "The whole race is wiped out,

utterly exterminated, as soon as it arrives at maturity and physical perfection, in order that the perpetuation of the species may be assured." Our ways, thank God, are not Nature's. Indulge as we may in speculation on the improvement of the race, in practice we care nothing for the species, only for the individual. Reversing Nature's method, we are careless of the type, careful only of the single life. Year by year unwilling witnesses of an appalling sacrifice, as fruitless as it is astounding, year by year we physicians sit at the bed-sides of thousands upon thousands, chiefly of youths and maids, whose lives are offered up on the altars of Ignorance and Neglect. Walking always in its shadow, compassed always by its sorrows, we learn to look on death with mingled feelings. There is the death that comes with friendly care to the aged, to the chronic invalid, or to the sufferer with some incurable malady. Very different, indeed, is it with typhoid fever. A keen sense of personal defeat in a closely-contested battle, the heart-searching dread lest something had been left undone, the pitifulness of the loss, so needless—and, as a rule, "in the morn and liquid dew of youth"—the poignant grief of parents and friends, worn by the strain of anxious days and still more anxious nights—these make us feel a death from typhoid fever to be a Delian sacrifice.

For fifty years the profession has uttered its solemn protests, as I do this day; Mr. President, we have done more—*we have shown how the sacrifice may be avoided and the victims saved.*

SHOCK.[1]

By ROBERT H. M. DAWBARN, M.D.,
OF NEW YORK;
PROFESSOR OF OPERATIVE SURGERY AND OF SURGICAL ANATOMY IN THE NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL; VISITING-SURGEON TO THE NEW YORK CITY HOSPITAL.

If we study the world over the causes of fatality following major operations, we find either sepsis or shock at the head of the list. Of recent years there has progressively been a lowering of the mortality due to infection of wounds; but is this true of the proportion of deaths from shock? It has seemed to me that for many years little advance has been made in our method of handling shock. No surgical topic more deserves our research; none receives it so little. An infinite number of minor topics takes up the time of our investigators, but this, the great lion in the road to recovery, is avoided to a degree that is surprising. How can one help feeling astonished at such neglect who observes that even the most recent surgical text-books almost ignore it? For example, in New York State, two prominent works, recently issued, of 1240 and 1600 pages, respectively, devote the one, four, and the other three pages to the entire topic of shock! The same is true of the largest and most recent London work on surgery, of 2272 pages, which devotes four of them to the greatest cause of surgical deaths (next to infection),—not much more space than is devoted to bunion!

Space precludes a discussion of the pathology of shock, and yet a few sentences are necessary in order to make clear the views upon which at least in part the treatment is based. Doubtless, the last word has not yet been written on this topic. Nevertheless, the experiments of Professor Golz of Strassburg[1] have never been successfully contravened. They are well known to all surgeons.

We may divide our cases of shock into, *first*, those in which the cause, whether a physical or a mental blow at the nervous system, partially abrogates the functions of the sympathetic nervous centers; *second*, where the cause partially abrogates the functions of the cerebrospinal nervous centers, as well as of the sympathetic.

In the first group the brain does not succumb to the blow. It is still capable of performing its functions fairly well. The sympathetic nerves, however, no longer properly invigorate the cardiac ganglia, and the tone of all the blood-vessels is also lost. Because of the weak heart-action the blood tends to accumulate in the veins. The patient bleeds inwardly, that is, into his own veins. The blood, like any fluid, must move in the direction of least pressure, and so it accumulates in the relaxed, dilated veins, leaving the arteries partially emptied. The condition in its resultant symptoms is identical with internal hemorrhage. I know of no surgeon capable of making a diagnosis between this not very uncommon type of shock and inward bleeding. It is interesting to note that Professor Hare has recently shown that death from chloroform narcosis is really death from shock; his words are: "The man is suddenly bled into his own veins and capillaries as effectively as if into a bowl."

We should note that in this, sometimes called the erethistic type of shock (to distinguish it from the commoner torpid or apathetic type), the victim is usually perfectly conscious until nearly the moment of death; occasionally, toward the end, he is a little delirious or even convulsive, from cerebral anemia. He is restless, tossing about; he is thirsty, and yet often nauseated; he sighs for more air; his skin is cold, pale, and wet; his pulse is rapid and feeble. Are

[1] Read at the Ninety-third Annual Meeting of the Medical Society of the State of New York, held at Albany, January 31 and February 1 and 2, 1899.

[1] *Virchow's Archives* for 1875. "Ueber den Tonus der Gefässe und seine Bedeutung für die Blut bewegung."

not these, each and all, the signs of inward bleeding? But they are just as truly the signs of the erethistic type of shock. I am personally cognizant of two instances in which a famous gynecologist, a man of great surgical experience, treated a patient *post-operationem* for shock, but the autopsy showed the abdomen to be full of blood, due to a slipped ligature of the stump. In the one case (shock) the bleeding is *into* the paralyzed and dilated vessels; in the other (hemorrhage) *out* of the vessels. But the symptoms are one and the same, and are due mainly to lack of blood in the brain and heart.

In the second and commoner type of shock—the torpid or apathetic—not only the sympathetic system, but also the cerebrospinal centers, have felt and partly succumbed to the blow. The patient is, in the milder cases, mentally benumbed; in the worse ones, quite unconscious. Because of this benumbing of the higher centers, the signs of this, the commonest type of shock, necessarily differ very much from those of the first type described. He does not suffer, as would an active brain, from dyspnea, nor is he restless, nor does he complain of nausea or of thirst. He has, however, the cold, pale, sweating skin, the rapid, feeble pulse, the shrunken features of inward bleeding. Often he has lost control of his sphincters. Sometimes he is a little delirious or convulsive—more commonly, simply in stupor. His symptoms are precisely those of hemorrhage, except as just stated, and the reason for the difference is obvious.

The only condition (save inward hemorrhage) which can be confused with shock is fat embolism, and the differential diagnosis is not difficult. It is a special danger of fractures, and lacerations of or operations upon fatty tissues. At first the lungs suffer most from the infarction; later, if the patient survives and the fat is forced on through the pulmonary capillaries, the kidneys and other organs may also undergo fatty embolism. Five points aid in clearing up the diagnosis: (1) The time at which fat embolism develops. This, as compared with shock, is usually late, from two to three days after the injury. (2) The cyanosis, due to plugging of the vessels of the lungs. (3) The extreme dyspnea, with very rapid breathing and sometimes bloody foam or even hemoptysis. (4) The mental excitement which often ushers in the symptoms. (5) The presence of fat in the urine.

Causes of Shock.—These are properly divided into I. *predisposing*, and II. *exciting*.

I. Under the first head, fear is a considerable factor. I know personally of one fatal case in which the subject, shown by an autopsy most carefully made to have no apparent lesion or disease of any organ, died apparently of sheer cowardice, some hours before the time set for operating upon piles. His agitation and fright rapidly increased, and he suddenly collapsed, dying within an hour, and with symptoms of shock. All measures tending to reassure patients and to calm them are of utmost value in preventing shock. This is one reason why the writer always prescribes whisky and a little morphin with atropin an hour before operation. The patient, otherwise more or less frightened, takes his anesthetic in a calmer, an almost cheerful, frame of mind. Also, as these drugs are analgesics, less ether or chloroform is needed than otherwise, and hence there is less danger from it.

We should not forget, as one peril from major operations under minor anesthesia, that a conscious patient must be nervously affected in an unfavorable way by hearing the saw grating through his bone, or by seeing the bloody paraphernalia used, etc. All this tends to invite shock. To illustrate, an aspirating needle may safely be introduced in several directions into the brain of a patient who is under general anesthesia; whereas, the same needle would probably cause prompt death from shock if driven into the brain of the same patient while conscious. Futhermore, a conscious patient whose thoughts are diverted elsewhere, at the time of being cut, is apt to feel much less shock than one who is nerved to the suffering he is expecting. It is easier to snap a tense thread than one relaxed. All military surgeons have noted that a soldier severely wounded in battle may not realize it at all, for some time thereafter; and will suffer less from shock than if he were to lie down on the table in a state of expectancy, and while conscious receive an equally grave physical injury.

From the above points it follows that although one may, for example, amputate a thigh painlessly under cocain or other minor anesthesia, it may very possibly result in a greater degree of shock than would have followed general anesthesia.

Under the heading we are discussing comes also impairment of vital energy by uremic or lithemic or diabetic troubles, or other constitutional dyscrasias; by opium or certain other habits; by prolonged sleeplessness; by business worries or other anxieties; by recent illness; or by either infancy or extreme old age. Sometimes, too, there is a family inheritance whereby the slightest operation proves perilous; whereas, on the other hand, we occasionally find a man whom the most scientific surgeon can hardly kill—such is his vital resistance to shock.

II. *Exciting Causes of Shock.*—These may come in the form of either mental or physical blows. We

are now discussing the latter, mainly; and regarding operations, there are four of chief importance. These are: (1) Loss of blood; (2) length of operation; (3) excessive major anesthesia; (4) loss of vital heat during operation.

1. As to the first of these four: with advancing years a surgeon has an increasing respect for a drop of blood. Hemorrhage is not the only cause of shock; indeed, one may die from shock produced by a blow on the abdomen, and without any bleeding. Nevertheless, hemorrhage is certainly the main cause. Shock is apt, in its severity, to be directly proportionate to the amount of blood lost.

2. As to the length of the operation, here is a matter too often neglected. In abdominal work, especially, speed is only second to asepsis as the leading factor in success. If the operation lasts an hour or more in a given case, the patient is apt to "die cured"; whereas, with half the time, or less, the great sympathetic centers do not suffer so terribly from the exposure. The most successful gynecologist I know operates with a speed like a sleight-of-hand trick.

Since the introduction of anesthesia, the really rapid operators have become few; and not all surgeons seem to realize how prejudicial to the patient it is to prolong an operation for the purposes of demonstration to the bystanders. I think it would be well if certain operations of grave peril were more often *parted in the middle*, so to speak. In the enucleation of some great tumor of the neck, for example, which has already taken much time, and promises with the careful dissection needed to occupy as much more, and in which the patient is weak—here let us leave our work unfinished, apply a sterile dressing, and wait two or three days if need be, until he is fit to bear the remainder of the cutting. Of course this is no new idea, but it is much less often adopted in practice than would seem wise.

3. As to excessive depth of major anesthesia, we all know that quite aside from the severity of the accompanying operation, this jeopardizes the patient's chances of escaping shock. Occasionally we see the surgeon permitting his assistant to keep the patient snoring heavily throughout. As a rule this, which is an indication of deep paralysis of the velum palati, is needless and worse.

4. It invites also the fourth main cause of shock enumerated—loss of vital heat. Prolonged and profound anesthesia, as we all know, results in a heavy fall of bodily temperature. And too often careless exposure of the subject upon the table adds to this chilling.

Treatment.—It is the chief purpose of this paper to endeavor to emphasize the extreme value of certain means of preventing shock which would otherwise develop. Upon this plan of campaign against this great enemy can we alone rely for better figures of mortality than those of the past. If we wait until shock has actually struck its blow, too often that blow proves deadly. Where the gravity of the operation or severe loss of blood or other cause makes shock a probability let the surgeon use the "ounce of prevention" by striking first!

Of course we should endeavor to build up the patient's vital resistance by all means in our power. Where weakness from a constitutional dyscrasia or from any removable cause exists the indication for a preparatory line of treatment is plain. In most cases it is also well to exhibit strychnin in minute doses for several days before a major operation, thereby invigorating the nervous system. But the chief reliance, the one which is already working wonders in the hands of those who know how to use it, is the free use of intravenous, hot, saline infusion injected while the patient is still upon the operating-table and asleep from the anesthetic, in cases where the advent of shock otherwise seems a probability.

The use of saline solution to treat a patient already collapsed from shock is not a new thing. Neither is it a brilliant success, because nothing is, when severe shock has actually arrived. Some textbooks mention it with dubious praise; others almost or quite ignore it. But the thing which is my own suggestion (so far as a study of the "Index Medicus" and the New York Academy of Medicine Library enable me to judge) is the use of this great weapon for good at the right time and the right temperature.

This plan for the prevention of shock has been in use in my clinic since the autumn of 1891, as a consequence of conclusions reached after several months of experimental work upon dogs, with hot and cold vascular saline infusion after bleeding, testing intra-arterial pressures at differing temperatures of the injected fluid, with the kymograph and the mercurial manometer, under the kind supervision of Professor Curtis in the Columbia University Physiological Laboratory during the winter and spring of 1890-91. So far as I have seen printed evidence other surgeons did not until later adopt this plan in prevention of shock,[1] and it is commonly ignored even today by the bulk of the profession.

In evidence of priority is submitted a brief quotation from the writer's paper read before the Surgical Section of the New York Academy of Med-

[1] Dr. F. Lange did, however, in 1888, advocate diluted claret by rectum to prevent shock, where a very bloody operation was anticipated; and Drs. Weir, Tiffany, and others in the discussion approved of water in this way. ("Trans. Am. Surg. Ass'n," vol. iv, p. 540, *et seq.*)

icine, November 9, 1891, and published in the *Medical Record*, January 2, 1892: "Whosoever has noted the vigor with which unstriped muscle everywhere reacts to the use of heat—for example, the much stronger and decidedly more permanent uterine contractions which result from hot post-partal injections as contrasted with cold ones—must believe it probable that such unstriped muscle, forming as it does a most important tunic of the blood-vessels, would be greatly aided by hot saline infusion in regaining its lost tone. Perhaps, too, the central sympathetic centers would feel and respond to this stimulus. Now, since a more vigorous cardiac action (for the heart, though striated, responds to the heat), accompanied by a somewhat restored vascular tone, would go far toward recovery both from hemorrhage and its attendant shock, I have felt that the experiment was well worth trying." (I had tried it as a preventive of shock upon dogs only, before the paper was written.)

Again, a quotation from the writer's article in the *Medical Record* for November 12, 1892: "And why would it not be well at the end of any and every operation grave enough to make shock a probable result (though, because of the ether, not as yet at hand), to inject subcutaneously (*i. e.*, intravascularly) a quart or two of hot salt-water? It would be painless, the patient not yet being out of anesthesia. It would certainly be harmless. And I believe it would do much to prevent, by maintaining filled blood-vessels, otherwise fatal shock from developing. It seems not improbable that we shall ultimately see this done as a matter of routine after all severe operations." At that early date the writer had tried the method in but very few instances to prevent shock, using a half liter or more within the vessel and as much more in the cellular tissues; and could not, of course, speak as all can to-day who have used it properly, with absolute certainty as to its value upon human patients.

In this connection five points deserve especial consideration:

(*a*) The place of entrance, (*b*) the proper solution, (*c*) the proper temperature of that solution, (*d*) the proper amount, and (*e*) the speed of introduction.

a. In most cases the median basilic vein is chosen for the cannula. Occasionally a vein in the operating-wound will do. The writer demonstrated some years ago that if one is caught short of tools—has no scalpel, no cannula, no dissecting forceps nor retractors at hand—the saline infusion can safely be made to enter the common femoral artery (which, being large enough to admit a lead-pencil, can always be felt pulsating if the patient still lives) by aid of a hypodermic needle attached to a Davidson syringe or a fountain-syringe.[1]

We must not neglect to mention that when speed is not a factor—when a prompter stimulant effect is not essential—the rectal route is an excellent one. Even during the operation the maintenance of a full, large bowel by means of Kemp's rectal irrigator can only be of benefit and is additionally a means of safeguard against dangerous chloroform narcosis—by maintaining filled vessels. And after the patient is removed to bed it is sometimes wise (in order to maintain the good effects of the intravascular infusion until the danger-point is well past) in bad cases to give the hot colonic irrigation alternately, an hour on and an hour off, for perhaps a half day.

When, following confinement, the accoucheur has a partly exsanguinated patient, he adds wonderfully to her comfort if he injects high up a couple of liters or more of very hot salt water by rectum. It is instructive to note that not a drop of the amount thus poured into the colon will ever be seen again. It is taken up greedily by the thirsty blood. In an emergency, elevating the foot of the bed upon a high chair and pouring in the salt water through an ordinary tin funnel inserted in the anus suffices. If the loss of blood has been extreme, intravascular infusion should also be employed; for the condition of the bowel-wall, and of the refuse material coating it, may, at times, have an adverse effect upon ready exosmosis of the salt water from the intestine, rendering this route perhaps less trustworthy.

As to hypodermoclysis, it is the slowest of all methods. The lymphatics are not very speedy in permitting the diffusion of water entering the connective tissues. Also, if the proper bulk of fluid is so introduced, it means quite a number of punctures, painful the next day. To prevent shock, then, I do not advocate this route so much as others. Upon its special value at times in choleraic infant diarrhea I have heretofore written.[2]

b. The fluid used should be the so-called normal, really decinormal, salt solution; which is six parts of common table salt per thousand, boiled, and filtered; roughly, a heaped teaspoonful to the liter or quart. So far as we are able to observe, this is as good, practically, as more complicated formulæ resembling more closely the exact chemical composition of the blood-serum. The use of blood transfusion, both for treating post-hemorrhagic conditions and shock, has been entirely dropped, as no more effective at the moment than saline infusion, and as being dangerous, later, both from possible embolism and from

[1] For details, again discussed, as to this emergency method, see *Medical Record*, December 10, 1898.

[2] *Medical Record*, November 12, 1892; also, December 10, 1898.

the certainty that every blood-cell so introduced will speedily break down, threatening to clog the liver and kidneys with the waste products of destructive or retrograde metabolism of tissues.

It does not seem so widely known as should be the case that plain warm water, devoid of sodium chlorid, must not be used intravascularly. For example, in a recent article, in the *Medical Record*,[1] upon "Saline Infusion," the author, Dr. Reilly, copies without adverse comment a most dangerous bit of advice from Messrs. Bosc and Vedel, namely, that "ordinary water is non-toxic, not very destructive to the red corpuscles, and might be used in an emergency." Also, in the "Transactions of the London Obstetrical Society" (meeting of December 6, 1893) may be seen a similar suggestion by a member, Dr. Horrocks, who was of opinion that the salt was a luxury, but not a necessity. He did not claim, however, actually to have ever used plain water in this way, and no member present agreed with him in advising it. It is certain that whosoever tries this, will, if the water be used in the customary large amount, kill his patient with quite indecorous speed by a wholesale disintegration of the red discs. The addition, however, of even so small a proportion of salt as six-tenths of one per cent. renders it safe for vascular infusion. Perhaps a quotation from an experiment of mine at the Columbia University Physiological Laboratory may emphasize this point, which surely needs emphasis.[2] "On May 15, 1891, I operated on a large dog, weighing before operating 16.77 kilos. On the one-in-thirteen hypothesis (of blood to body-weight) his weight of blood would have been 1290 grams, or, allowing for the specific gravity of blood, about 1222.75 c.c. The cannula of the mercurial manometer was introduced into the right carotid. The right femoral was used for bleeding, the left femoral for injection of the hot salt solution. Professor Curtis superintended the working of the kymographic needle. Dr. F. J. Brockway assisted me. We drew 563 c.c. of blood." Upon attempting to replace this, and a smaller subsequent bleeding, by the salt solution with which at various temperatures I was experimenting, "a mistake"—a most interesting and instructive one—was made. Dr. Brockway and I each supposed that the other had added the salt to the hot water, whereas in fact neither had done so. And within a minute after receiving a considerable amount of this plain-water injection the animal died." Previous dogs, bled to an equal degree, had done beautifully and recovered under saline infusion. Hence, we were much puzzled until Professor Curtis asked if the salt had been added, and stated that without it water in considerable amount will kill almost as quickly as prussic acid—and in the way already named.

c. The proper temperature for the injection-fluid is *as hot as the hand can bear*, and this is about 120° F. or 49° C. (Of course the temperature at the heart, when the great bulk of blood has diluted the slowly entering fluid, will be much lower than this.) There need be no fear of injuring the blood or other tissue by such heat. Very many times the writer has now used it, and never with cause for subsequent regret. This point seems not at all well-known as yet in the profession, and nearly all the text-books still advise infusion at about 100° F. The higher temperature here recommended is very stimulating to the flagging heart, and maintains the tone of the muscular tunic of the vessels. This is well illustrated in the photographs I now show you of kymographic carotid tracings at various temperatures. So recently as last winter Dr. Robert Coleman Kemp, at the Columbia Physiological Laboratory, in pursuing some investigations in a somewhat different line, had occasion to repeat my manometric and kymographic experiments of some seven or eight years ago, and re-verified their correctness—he, too, finding that at 118°–120° F. the tracings showed the best results upon heart and vessels. His statements were published in the *Record* early last autumn.

To maintain the desirable degree of heat, the reservoir containing the water should be wrapped in a large warmed towel or sterile blanket during the time occupied by the act of infusion.

In Dr. Reilly's article, quoted, he mentions a conclusion of Athansin, a French experimenter, upon this matter of the proper heat, which I must believe to be an error. He says: "In animals, at least, solutions having a temperature of 165° to 175° F. can be safely used." Now, upon reference to Kirke's "Physiology," eleventh edition, p. 846, it will be seen that globulin coagulates at 70° C. (158° F.), and Dalton's "Physiology," seventh edition, p. 80, affirms that serum-albumin clots at 72° C. (162° F.).

It will be noted, however, that both 158° F. and 162° F. are about 40° F. hotter than the hand can support, as above stated. So that the temperature which I advise is a long way from being unsafe. The hand-test of the heat, as suggested, will be found both safe and accurate enough in actual practice.

(*d*) The proper amount of the injection-fluid may be set down, for the adult, as never less than a liter, often two liters, and occasionally, perhaps even three liters, injecting always very slowly. To

[1] November 12, 1898.
[2] See *Medical Record*, January 2, 1892.

give a half-liter or less is, for the prevention of shock, almost valueless. The upper limit of safety has not as yet been very exactly formulated. The kidneys readily remove any water from the blood in excess of its needs. Should these be diseased, a less amount must of course be employed than otherwise.

(*e*) The time occupied in introducing the fluid into a vein should never be less than ten minutes per liter. To be sure, I have seen it caused to flow with double this speed and without ill effect; but, on the other hand, a temporary period of threatening heart-failure due to this cause—a rapid overstimulation—has been at times observed.

Of late we have all noticed in the journals that a few enthusiastic friends of this plan of preventing shock by saline infusion are using it at the *beginning* of the operation—before even a drop of blood has been lost, or any strain whatever put upon the nerve-centers. If this were only done by the plan of keeping the large bowel full of hot salt-water I should find no fault, for here the blood will to some extent take up water only as it needs it. But I doubt the wisdom of the preliminary distention of vessels by intravenous infusion; for one reason, because it is plain that by such a practice we add to the amount of blood lost. For every spurting point will, from increased pressure, spurt much more vigorously before it can be caught, than otherwise it would do.

Just a word as to the repetition of the dose. Many times I have read of surgeons using it once in a given case and reporting a temporary good effect, but that subsequently the patient died of shock. Now, of course no method can save all cases of every dangerous disease; but common sense would teach us that if a dose obviously does good it should be repeated, and this so long as the same indications call for it. From this it does not follow that we must open a vein again and again. The rectal hot saline douche will if rightly used, give approximately as good results for such purposes. The bed should always have its foot elevated very high, and this should remain so until danger of shock is well past. This position maintains a better supply of blood to both brain and heart, and also helps in the retention of the fluid in the large bowel. Alternately an hour on and an hour off seem to produce more desirable results than a steady maintenance of the flow through Kemp's tube. I think it wise not to consider the patient past his danger until the pulse becomes as low, at least, as 120 per minute, and shows no tendency to occasional increase above this number.

Thus far I have discussed the *prevention* of shock, but have said nothing as to its treatment when actually developed and threatening the patient's life. Concerning this last I have little to say, and that is not new. If we are unfortunately called to an accident case, and find the victim in collapse, which is another name for shock, hot saline infusion is worth trying—but with small hope. Strychnin hypodermically is probably, when used freely, our best reliance. Some surgeons use it even to the point of producing slight spasms—if the shock does not yield earlier. Hot applications about the person are essential—elevation of the foot of the bed, a help. But two prominent "*donts*" should never be forgotten, namely, *dont* overstimulate the heart, and *dont* give a particle of food by mouth nor any medicine even remotely capable of causing nausea.

If the pulse comes down to anything like reasonably safe numbers—as discussed a minute ago—let well enough alone; for if that tired heart be overwhipped it is likely to quit work. And as for the second "*dont*," what is nausea in all of its symptoms but one type of shock? There is the cold, wet skin, the weak pulse, the sensation of vital collapse; and no one should take the least risk of adding this—if not already present—to the surgical shock.

The duration of shock is not many hours, as a rule—as to its worse phase. Certainly it is not so prolonged but that the patient may easily have his strength sustained during this period, without using his stomach—by nutrient enemata, or hot coffee by rectum, etc. And any needful remedies which might otherwise nauseate can surely also be administered by this route, or better still, by needle. I dwell upon this matter, because one so regularly sees this "*dont*" neglected, to the patient's detriment.

I wish that time permitted a discussion of the question of amputation of crushed and lacerated limbs during shock, and of the relation of anesthesia to this problem, but this is impossible.

THE TREATMENT OF PATIENTS SUFFERING FROM PULMONARY TUBERCULOSIS WHO CANNOT GO AWAY FROM HOME.[1]

By DE LANCEY ROCHESTER, M. D.,
OF BUFFALO, N. Y.;
ASSOCIATE PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO.

I beg leave to introduce my remarks by the report of two cases:

Case I.—November 13, 1897. J. P. B., male, aged twenty-five years; nativity, U. S.; occupation, bank clerk; single. Family history good. Personal

[1] Read before the New York State Medical Association at its Fifteenth Annual Meeting, held at New York, October 18, 19, and 20, 1898.

history: Residence in lower part of city, on rather low land, in brick house without cellar; very little sunshine. Habits good. Scarlet fever in childhood. Four and one-half years ago had so-called "nervous fever"; sick with high fever for four weeks; probably typhoid; complete recovery. In April, 1897, had an attack of epidemic influenza; since then has coughed constantly; has had almost daily an afternoon rise of temperature and frequent severe night-sweats. Appetite poor; bowels regular; temperature in afternoon 102.5° F.; tongue broad, pale, flabby, and covered with slight gray coating; pharynx pale; larynx normal. Physical examination of chest revealed infiltration of both apices with softening and small cavity in right upper lobe and infiltration at base of right lung. General bronchitis throughout both lungs. The amount of sputum in twenty-four hours was 200 c. c., mucopurulent in appearance and nummular, containing many pus-cells, some pus-organisms, tubercle bacilli, micrococcus tetragonus, and elastic fibers. Weight 149 pounds. Height 6 feet 2 inches.

This case was not one that promised well for treatment, but I explained to the young man the nature and character of his disease and impressed him with the importance of attention to every detail of the treatment suggested and encouraged him in the belief that by persistence in treatment he might recover. The treatment instituted was as follows: An out-of-door life; sitting, well-wrapped up, on the veranda, when rain, wind, or wet snow prevented walking; at other times walking in the open parts of the city where purer air could be found; careful attention to a daily evacuation of the bowels; a full warm tub-bath once or twice a week and a cool sponge followed by brisk rubbing every morning; regularity in hours of meals and slowness of mastication and swallowing of food; food to consist chiefly of meat, eggs, baked potato, boiled rice, stale bread and butter, and some of the green vegetables, fruits, and plain desserts; beverages, milk (not to be taken at the same meal with meat), water, cocoa or chocolate, coffee in moderation. The medical treatment consisted of a proper emulsion of cod-liver oil and the administration of guaiacol and terebene emulsified with milk of magnesia and syrup of tolu, and the use of an inhalation containing one gram of menthol and two grams each of spirits of chloroform, guaiacol, terebene, eucalyptol, and thymol. Five to ten drops of this on absorbent cotton was packed tight in a cigar-holder inhaler for constant use, the drops and cotton being renewed every two or three hours.

He has been under this treatment for eleven months and has made constant but slow improvement. The entries on my record book are as follows: February 14, 1898: Improved in all respects. Weight 155 pounds 10 ounces. May 9, 1898: During last two weeks has not felt so well; has coughed more; expectoration, however, is somewhat less (150 c. c.), varying somewhat from day to day; the elastic fibers have become much less; tubercle bacilli decidedly fewer in number, but the pus-cells and organisms remain about the same and the micrococcus tetragonus is still present. Physical examination still shows the evidence of infiltration of upper right lobe, though the evidences of active softening have disappeared and the cavernous breathing is becoming more bronchial in quality and pitch. The evidences of infiltration of left apex show that the area is much diminished and the evidences of infiltration of the right base have disappeared; there remains, however, sibilant and sonorous breathing with râles throughout both lungs. Weight 155 pounds, 4 ounces. At this time there was added to his treatment the following mixture:

℞	Balsami copaibæ	6.00
	Mucilag. acaciæ	50.00
	Morphin. sulph.	0.10
	Ol. menth. pip.	0.10
	Ol. amygdalæ amaræ . . .	0.20
	Syr. tolutani	44.00

A teaspoonful of this was taken every four hours. From this time on his improvement continued uninterruptedly. On June 9th his weight was 156½ pounds; the expectoration had diminished to not more than 100 c. c. in twenty-four hours, the elastic fibers could no longer be found, there was only an occasional micrococcus tetragonus, and very few tubercle bacilli, but pus-cells and organisms were still present.

I did not see the man again until October 10th. He told me he considered himself well and for the last month had taken no medicine but cod-liver oil, but had continued the use of the inhalation. He has almost no expectoration; succeeded in saving only 2 c. c. in forty-eight hours. Careful examination of the centrifuged sample shows no tubercle bacilli, no micrococcus tetragonus, no elastic fibers, and only a few pus-cells and organisms. The physical examination of the chest gives no signs of disease except bronchial breathing in the right supra- and infraclavicular region and increase in vocal resonance in the same regions and in the right interscapular region. Not a râle is to be heard. His weight is 161½ pounds.

CASE II.—March 18, 1898. Mrs. G. W. K., U. S., aged thirty-six years; occupation, housewife; residence, country village; well built, dry house. Habits good. Family history: Parents both dead at the age of sixty-nine years, mother of dysentery, father probably of some form of heart disease. One sister died in childhood of dysentery and one of acute phthisis following childbirth. Personal history: Patient has had all of the acute infectious diseases of childhood; has been well since then until present illness began; has two children, eldest three years old, youngest three and one-half months old.

The patient did not nurse her first child; nursed her second child for three weeks, but had to stop on account of very sore nipples. She said she took cold when the baby was four weeks old and had coughed ever since; *i. e.*, for two and one-half months. On February 3d raised one ounce of dark blood. Her greatest weight has been 120 pounds; her present weight is 111 pounds, 10 ounces. She is pale and

thin in appearance, has irregularly recurring chills and fever and occasional severe sweats. Her temperature at 2 P.M. is 103° F., respiration 22, and pulse 134, small and compressible. She sleeps badly on account of cough which is much worse at night. She has been distinctly hoarse for a week or ten days. Her appetite is poor but she seems to digest her food and has no gastric distress. Her bowels are persistently constipated. Her capillary circulation is poor as evidenced by cold and bluish hands hands and feet. Examination of her throat shows a pale pharynx and infiltration of the posterior laryngeal wall, with swelling of the arytenoid cartilages and some redness of the vocal bands.

Physical examination of the chest reveals a weak cardiac first sound with marked accentuation of pulmonary second sound. Tubercular infiltration in upper lobe of each lung with cavity of considerable size and small cavity in left. She did not bring her expectoration with her but said it was considerable, chiefly raised at night and early in the morning.

I sent her home with a very bad prognosis, writing to her physician that I thought her case was one that would go on rapidly to death but that it was always well to try in cases of tuberculosis even though they seemed hopeless. I gave her a diet-list and wrote out the following directions for her daily life: Sit out of doors all day long, covered sufficiently and protected from inclemency of the weather. As strength returns take drives and finally walks. Take a tumblerful of hot water every morning one hour to one-half hour before breakfast, and a tumblerful of cold water one-half hour before each of the other meals. One hour after breakfast, whether there is desire or not, have a movement of the bowels, inducing it by enema if it cannot be had otherwise. Three hours after breakfast take half a pint of milk with a raw egg and a tablespoonful of whisky or sherry stirred in it, and a very little sugar. Three hours after dinner take the same or a cup of chicken broth with a teaspoonful of somatose stirred in it. Three hours after supper take half a pint of hot malted milk. With the noon meal drink a pint of lager beer or half a pint of ale or porter. Every morning use a cold-water spray over the shoulders and chest in front and back, followed by rubbing with a soft crash towel. A cold sponge-bath every afternoon at 4.30 or 5 o'clock, followed by a similar rub. A full hot bath in the tub once or twice a week. Dress warmly with wool next the skin, but never wear a so-called chest-protector and never wrap anything around the throat. The medicinal treatment included the same inhalation as in Case I. and the same guaiacol and terebene emulsion.

On May 15th her physician wrote reporting improvement in all respects. On July 15th she again came into my office feeling much better. She had gained three pounds in weight; the chills and sweats had disappeared; her temperature was 100° F., though she said she no longer had fever. her pulse was 100; her respiration 20. Appetite had returned; bowels were still constipated; she slept better, coughed and raised less; hoarseness had disappeared. Examination showed that the swelling and redness of the larynx had disappeared; there was still the cavernous breathing in each upper lobe, but there were almost no râles. Presuming upon her improvement she had already begun to let up on the strict carrying out of instructions. I tried to impress upon her the importance of persistence, but I have since learned from her physician that she is failing, again having the chills, fever, and sweats, but not to the same severe extent as formerly.

I have chosen these two cases from quite a large number because neither was a promising case for treatment, but each shows how much can be accomplished by persistent trying. For the examination of the sputum in these cases, as in all my others, I am indebted to Dr. Nelson G. Russell. For the formula for the inhalant and the suggestion of the cigar-holder inhaler as well as for the pharmacal fact that guaiacol can be made into emulsion with milk of magnesia, I am indebted to Dr. W. H. Woodbury.

With these cases as a text I desire now to make a few remarks in regard to the treatment, hygienic, dietetic, and medicinal, in cases of pulmonary tuberculosis. I wish to emphasize the fact that we are called upon to treat *cases* of pulmonary tuberculosis and not pulmonary tuberculosis in the abstract, and that the careful study of each case is of the utmost importance in outlining the treatment, the treatment of different cases of pulmonary tuberculosis differing fully as much as the treatment of typhoid fever differs from that of pneumonia.

Of equal importance with, if indeed it is not of greater importance than the medicinal treatment of pulmonary tuberculosis is its hygienic management. Many years ago a prominent physician of Boston, recognizing that he had pulmonary tuberculosis, stopped work and drove in a buggy, his wife accompanying him, through the State of Massachusetts, taking a year to do it. He recovered without medication and reared a family of twelve sturdy children. The diary that he kept on this journey is an interesting medical history. He drove in all sorts of weather and through a variety of scenes and a diversity of atmosphere that would go to show that climate in and of itself is not of so great importance as sometimes appears. What was the great factor in his recovery? An out-of-door life in pure air. He avoided the cities in his journey and lived a regular life as to meals and the functions of excretion.

The most important factor in the climatic treatment of pulmonary tuberculosis is not the warmth, the dryness, the rarefaction of the air, but its purity, its freedom from extraneous matter of any sort.

Given a case of pulmonary tuberculosis in the incipient stage, when the normal resisting powers are not too much encroached upon and put the patient in a pure atmosphere, relieved of all worries, and he will get well. When we have a patient who cannot go away then we should, so far as possible, make a good home climate for him. Make him live out of doors all the time, sitting, driving, or walking, as may best be done. Next to the purity of the air, and a factor in producing it, is sunlight. Let him sit in the sunlight and stay on the sunny side of the street when he walks or drives. Let his room be the sunniest and airiest in the house and never have it entirely closed up. If possible have it heated by an open fire and thus procure good ventilation through the chimney.

As regards the personal hygiene of the individual the avenues of excretion should all be kept open to aid in the elimination not only of the normal excreta of the metabolism, but also of the poisons generated in the individual as a result of the infection. Recognizing that the normal excretory function of the lung is greatly interfered with by its diseased condition we must call on the other excretory organs to do its work. Not only the bowels and kidneys, but the skin, which is one of the great sewers of the body, must be kept up to its work. As far as the bowels and the kidneys are concerned they can be depended upon to do their share of the work if supplied with proper kinds of food and a sufficient amount of water. By the sweats which occur in acute infectious disorders and are followed by amelioration of symptoms more or less persistent according to the disease, Nature has pointed out to us that by sweating we can rid the body of many poisonous products. Dr. Charles G. Stockton of Buffalo first suggested to me the advisability of induced sweating as a means of preventing the drenching night-sweats of phthisis. In a limited number of cases this procedure seems to have been successful.

As far then as the hygiene of the skin is concerned in patients who are up and about a full hot-water bath should be taken once or twice a week, or a hot-air or steam bath once a week given in the late afternoon or evening and a tepid or cool sponge once a day given in the morning and followed by brisk rubbing. In the case of patients who cannot take this treatment on account of weakness a tepid sponge bath may be given every afternoon about five o'clock and a hot-air bath once a week. As regards the diet of a patient suffering from pulmonary tuberculosis very few general rules can be laid down. The digestive power of each individual has to be studied; there are the greatest varieties, from a normal gastric digestion to marked increase in hydrochloric acid and excessive motility of the stomach, the food being passed into the intestine in altogether too short a time or in the other direction to absolute achylia gastrica and great deficiency of gastric motility. The foods desirable for these patients are, however, meats, especially rare beef, eggs, baked potato, boiled rice, and boiled young beets; the drinks are water, milk (not to be taken at the same meal with meat), cocoa, and chocolate, and in moderation coffee or weak tea. The mouth should be kept clean with an aseptic wash and the food should be thoroughly masticated. So far as the respiratory system is concerned the nose, pharynx, and larynx should be put in good condition and kept so by the use of sprays and douches if needed.

The subject of exercise, both general and special, I have left for consideration by itself, for in this matter especially is it necessary to study each case. If the patient suffers from hectic fever, is expectorating profusely, or is having hemorrhage, even though slight, or if physical examination reveals marked involvement of one or both lungs general exercises should not be undertaken at all or very gradually and increased very gradually; under these circumstances pulmonary gymnastics should not be indulged in at all. The danger of too great general exercise is from the fact that the oxygenating surface is too limited to supply the demand. The danger of special pulmonary exercises is the possibility of scattering further through the lung the infecting foci through the process of inspiration pneumonia. Cases in which general exercise and special pulmonary exercises are useful are those in which there is only a slight local bronchitis or very slight pulmonary infiltration.

The medicinal treatment of a case of pulmonary tuberculosis is naturally divided into local and general. The local treatment consists in the application of medicinal agents for the purpose of curing or alleviating the morbid state of the tissues. The treatment of laryngeal tuberculosis will not be touched upon. The question arises, Can we reach the bronchial and alveolar mucous membrane with medicinal agents in any way to be of value? Evidently sprays and inhalations are our only means, but sprays rarely reach beyond the vocal bands or at the farthest, the trachea. They are of little use. The same thing may be said of inhalation of solutions of medicaments in the fixed oils, but inhalations of the essential oils seem to reach further and can be kept up almost constantly. Of the various essential oils the oil of peppermint is by far the best; it can be used in the form of the essence and seems to have a direct effect in diminishing pus and lessening cough. The cigar-holder is a cheap and efficient inhaler.

As for the general medicinal treatment, from the reports of many physicians tuberculin and antitubercle serum have been of undoubted value in early cases. In my own hands they have not as yet been successful. As far as my experience goes nuclein, administered hypodermically, is the best remedial agency in early cases. I have several cases of apparent cure from this treatment. Among remedies administered by the mouth, creosote, or some of its derivatives still stands at the head of the list. In the administration of creosote it is important in the first place to secure a pure article, to administer it regularly, always after food, to increase the dose gradually but regularly, carefully watching the urine, as well as looking for gastric disturbance. I have given as much as 2 c.c. at a dose three times a day for three months in this way. The gradual reduction of the dose is as important as the gradual increase in its size, the sudden stopping of the large dose sometimes producing very unpleasant results. The carbonate of creosote has not been of any greater value than the pure creosote, nor has it been better borne by the stomach. The same may be said of the carbonate of guaiacol as compared with guaiacol. In some cases guaiacol can be taken when creosote cannot. When there is a great deal of pus in the sputum terebene combined with the guaiacol is often of value. Balsam of copaiba is also often of great use under similar circumstances. It can be easily administered in emulsion with mucilage of acacia and syrup of tolu. In cases in which there is marked intestinal fermentation or gastric intolerance of pure guaiacol, the benzoate of guaiacol is often tolerated and acts very well. It can be given in doses, gradually increased, of from 0.25 to 1 gram, three times daily, in capsules. In all patients in whom it does not produce gastric or intestinal disturbance cod-liver oil is still our sheet-anchor in the medicinal treatment of phthisis; nothing has yet been found which can take its place. The pure oil can be taken by some individuals, but not by many. An emulsion can generally be made which will be tolerated by the stomach. After taking cod-liver oil for a while, whether pure or in emulsion, the individual generally becomes accustomed to it to such a degree as actually, in many cases, to like it. In these days of proprietary medicines and made-up emulsions, which are said to be strictly ethical, and are said to contain thus and so, whose working formulæ, however, are not published, many physicians are losing the art of prescribing, but really a freshly made emulsion, put up by a competent pharmacist, is much to be preferred to the made-up emulsions that are on the market.

Special symptoms in some cases call for special treatment. I should like to refer briefly to some of these. Pain in the chest is not infrequently a troublesome matter. Its cause should be searched out. If due to pleurisy it should be treated by strapping or dry cupping the chest; if it is a neuralgia it is best relieved by aconitia ointment locally, general treatment, and building up of the general resisting power. Sometimes the local use of iodin in ointment or tincture seems to be of avail, but in such cases it seems to me that time is as much a factor as the iodin. Cough is a necessary concomitant of pulmonary tuberculosis, and should not be too rashly interfered with. A troublesome, irritating cough with little or no expectoration is generally due to pleurisy or some disturbance of the upper air passages, and treatment should be directed accordingly. Cough is best treated by inhalations, such as have been suggested, or by the administration of hydrocyanic acid and chloroform water. Cough is frequently a matter of habit and can be prevented by mental discipline. The administration of cough mixtures containing stimulating expectorants and opium should be avoided as far as possible. It is very seldom that the stimulating expectorant has any place in the treatment of phthisis, and opium and its derivatives are absolutely out of place, except in advanced cases beyond recovery, in which nothing can take their place. To a patient in advanced phthisis opium is truly the great and good gift of God to man. Hemoptysis is best treated by rest in bed and the administratson of morphin and atropin, hypodermically.

The fever of tuberculosis is best treated by the sponging and general plan of treatment already suggested. The use of antipyretics is to be deprecated. Sweats are best combatted by general treatment and the baths and induced sweats referred to, but they sometimes call for special treatment. In my hands nothing can equal atropin in the relief of this distressing symptom.

Of the gastric symptoms requiring special treatment vomiting is the most distressing. Sometimes it is necessary to put the patient absolutely to bed in such cases. Careful investigation of the stomach with the tube is sometimes of value. In severe cases of vomiting in phthisis, however, whether induced by cough or not, large doses of cerium oxalate, 1 gram at a time, are of especial value. Of the intestinal symptoms diarrhea is the most serious. If the general treatment as outlined does not relieve this condition, benzoate of guaiacol is our most useful drug. In the distressing diarrhea of advanced phthisis, however, nothing can take the place of the lead and opium pill.

In closing my remarks I wish to make a plea for

the careful study of individual cases and the use of treatment especially adapted to each particular patient, and the avoidance of routine treatment of cases of pulmonary tuberculosis.

CLINICAL MEMORANDUM.

ASTRAGALECTOMY FOR INVETERATE TALIPES EQUINO VARUS, WITH REPORT OF A CASE.

BY JAMES K. YOUNG, M.D.,
OF PHILADELPHIA;
PROFESSOR OF ORTHOPEDIC SURGERY IN THE PHILADELPHIA POLYCLINIC; CLINICAL PROFESSOR OF ORTHOPEDIC SURGERY IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, ETC.

THE patient C. A. J., male, white, thirty-one years of age, a Swede by birth, and a cook by occupation was admitted to the University Hospital July 13, 1898. He was unable to work on account of his increasing deformity. His family history was good and his own health had always been excellent, except for the deformity, which was congenital.

The examination showed a marked talipes equino varus of the right foot. The astragalus was luxated. The gait was peculiar, the knee being turned far inward

FIG. 1.

Astragalectomy. Before operation.

in the effort to bring the foot to the ground. There was contraction of the extensor muscles of the toes.

On July 15th I operated, Dr. Willard having been called in consultation. A complete excision of the astragalus was performed and a division made of the extensor tendons of the toes and also of the tendo-Achillis. The incision was a long curvilinear one, beginning in front of the tendon of the peroneus longus and extending across the arch of the foot to the tibialis anticus. The joint was opened and the bone removed with a dry dissector, great care being taken to prevent injury to the posterior tibial artery as the inner portion was removed.

FIG. 2.

Astragalectomy. After operation.

The foot was brought into proper position and a plaster cast applied.

On July 26th the left foot was found to be deformed in like manner to the right, but in a much less degree. The extensors of the toes as well as the tendo-Achillis were divided and a plaster cast applied. The casts were kept in place six weeks, only being removed to admit of the antisepic washing and dressing of the wounds. On October 4th the following note was made: The patient has been walking about the ward on crutches since September 15th and has walked the length of the ward without crutches. Very little weight, however, can be borne on the right foot. On October 10th the patient was discharged, cured.

This case is interesting not only on account of its extreme rarity, very few surgeons having ever performed this operation in the adult, but because of the excellent and useful joint which results after the operation. The removal of the entire astragalus does not interfere with the motion of the joint. The malleoli adapt themselves to the tarsal bones and the joint is almost as useful as an ordinary ankle-joint. The difference in the length of the limb is from one-half to three-quarters of an inch. Prompt and uneventful recovery from the operation is the usual course in such cases, and the operation is to be considered as equivalent to an amputation or excision at this point, although the operation of astragalectomy is more difficult than either of the others.

MEDICAL PROGRESS.

Differential Diagnosis between Extra- and Intraperitoneal Rupture of the Bladder.—DITTRICH (*Deut. Zeit. f. Chir.*, vol. 50, p. 204) found by percussion over the symphysis pubis of a patient, whose pelvis had been crushed by the wheel of a wagon, a deep box-tone, more noticeable just before catheterization, and which increased after the patient had been catheterized several times. Each time after the catheterization the box-tone changed to a dull percussion-note. The urine came out through the catheter in spurts, due to the clonic contractions of the bladder-wall. Dittrich attributed this box-tone to the escape of air through the catheter, into the tissues around the bladder. As was shown by operation there was an extraperitoneal rupture of that viscus. If the bladder is ruptured into the peritoneal cavity, the air, which may be introduced by a catheter, will not have any effect on the percussion-note, and hence he regards this symptom as diagnostic of an extraperitoneal rupture of the bladder. When the incision was made over the symphysis pubis, air and bloody urine escaped, thus confirming the diagnosis in every particular.

The Plague at Bombay.—The *Indian Medical Record*, December 1, 1898, while congratulating the country on the mild character of this season's plague at Bombay, has this to say about the prophylactic handling of the disease in general:

"The laws of plague have still to be elucidated and in the dark as we are at present, we can only agree with those authorities who tell us that it runs a regular and predestined course, which all human efforts are powerless to check or perhaps even to modify.

"We used to hear a lot about stamping it out. It was at one time a favorite catchword with all plague officials, they know better now and the pet expression has departed from their reports. The most vigorous action on the part of the Bombay Government failed to have any appreciable effect upon the previous epidemics, while it had the ill result of interfering with the social condition of the people and of wearing out their patience.

"Now curiously enough when the most severe of the measures, which were considered an absolute necessity at first, have been abolished and while others have been modified and pared away to an almost invisible tenuity, the plague quietly takes it into its head to depart. All these things are strange and inexplicable paradoxes to the modern sanitarian with his shibboleth of isolation, segregation, and disinfection.

"Unfortunately the low death-rate in Bombay, averaging only 185 per week for October, and less than half of that for November, has not been universal in India, and in some districts there have been over a thousand deaths a week."

Poisons Produced by Animal Parasites.—PEIPER (*Centralbl. f. inn. Med.*, December 17, 1898) states that all the animal parasites contain poison or develop in their metabolism substances which act as such. Even ascaris lumbricoides is by no means so harmless as is generally supposed, and is capable of producing severe symptoms with indications of cerebral irritation. Its devastations are seen, for example, in the West Indies among the black races, and especially among the children. These ill effects are seen not merely in the vicinity of the worms, and cannot be explained by the motions of the latter, nor their abstraction from the diet of nutriment necessary to their host, but they are due to absorption of toxins or leucomains from the intestine. One thing noticeable in the round worm is its peculiar sharp odor, which often causes conjunctivitis in those who busy themselves with its growth in the laboratory.

The presence of tapeworms is occasionally followed by disturbances of vision. The anemia of bothriocepbalus, which is seen in only a few of the patients who harbor this parasite, is due to the action of a poison upon the red blood-cells. The anemia of anchylostoma is also to be explained by the presence of a protoplasmic poison, as the amount of the blood sucked by the parasites could easily be made good by the regenerating power of the system. The fluid in ecchinococcus cysts certainly contains poisonous material since the puncture of these cysts may cause peritonitic lesions, and even the death of the patient.

The epileptic attacks and psychic disturbances which accompany the presence of oxyluria in large numbers cannot be satisfactorily explained upon a theory of mechanical irritation alone. Trichinosis gives the picture of a severe infectious disease sometimes within a few hours of the ingestion of trichinous flesh, and no theory of mechanical irritation produced by the presence of the animal parasites will explain these symptoms. The author believes that all animal parasites contain or produce poisons which may act unfavorably on the nervous system or the blood of the host.

Tuberculosis of the Uterus.—VASSMER (*Arch. für Gynäk.*, vol. 57, p. 301) has had opportunity to observe six cases of tuberculosis of the uterus at the dispensary for women in Göttingen, during a period of ten months, and he regards the trouble as not nearly so rare as do some other writers on the subject. Four of these patients were in the third decennium, while two were older. The symptoms were chiefly pain in the pelvis and sacrum, without hemorrhage or discharge. The uterus was found to be more or less enlarged, according to the extent of the disease. The mucus from the cervix was not found to contain tubercle bacilli. The diagnosis was made by microscopical examination of scrapings from the body of the organ. The treatment was by curetting, and intra-uterine application of tincture of iodin in mild cases, and by removal of the diseased portions of the genital organs in the more advanced cases. The tubes, one or both, were affected in four of these six patients; in the other two, they were apparently free. The results of treatment were satisfactory, the only patient who did not survive being one with extensive abdominal and pulmonary tuberculosis, upon whom nothing more than an exploratory incision was made.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the MEDICAL NEWS will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

NEWSPAPER MEDICAL EXPRESSIONS.

WE are treated every now and then in the daily newspapers to an amusing series of misapplied and misconstrued medical expressions. Whenever some important occurrence calls, in the description of its incidents, for the use of medical terms and medical opinions we are sure to have a fresh display of delightfully unconscious but thoroughgoing ignorance. The recent death of the President of the French Republic has given an excellent opportunity to ambitious newspaper men to make "ducks and drakes" of medical expressions to their hearts' content. Of the tentative way in which the President's medical attendant's name has been spelled and misspelled and dissevered and mishyphened, we shall say nothing. It must be remembered, however, that Dr. Lannelongue is one of the best-known members of the profession in France, and was chosen at Moscow a year and a half ago as the president of the next International Medical Congress.

The Associated Press informed us, the morning after President Faure's death, that he had been suffering for some time from general paralysis. As he had been, until the end, one of the clearest-headed of men, and recognized by his associates in the Government as possessed of the highest practical executive ability, it is easy to see what we are to think of this. At his death, we are told that just before the end "one doctor had drawn the tongue to keep the lungs alive" (sic), while a second held a bag of oxygen to his nose. Equivalent mistakes with regard to unfamiliar court ceremonies and involving the misapprehension of national peculiarities might be forgiven, but medicine is a universal science, and any medical man if consulted would have been able to point out these patent errors. There would seem to be no good reason why modern progressive newspapers should insult the intelligence of a large number of their readers by ludicrous mistakes. The errors are mild and few on this occasion compared to what they can be and have been when the expense of cabling did not prevent an omniscient correspondent from wading far beyond his depth in the waters of medical knowledge.

Blunders such as these would not be tolerated for a moment if they had reference to movements in financial circles or were concerned with parliamentary or political or social happenings. Is there any good reason why the truth should be less precious in medical matters? Our American newspapers, at least, have gotten beyond that stage in their evolution where they can afford to be ridiculous in their methods of presenting news. It is time there was an end of it. Some one with trustworthy medical experience should, on an occasion like this, be consulted, and so save the infliction on an unoffending public of some of the ludicrous medical expressions we now have to bear.

SANITARIA FOR TUBERCULOUS PATIENTS.

WE present this week an abstract from the Fourteenth Annual Report of the Adirondack Cottage Sanitarium of Saranac Lake, N. Y. The report is pregnant with suggestion as to the therapeutic value of sanitaria in the treatment of tuberculosis. To one unaccustomed to the statistics of sanitaria it seems almost impossible that such results as are reported can be obtained in the treatment of that dread disease — tuberculosis. We gave sometime ago an abstract from the Report of the Loomis Sanitarium, and while we thought it well to criticize certain features of the report the general results ob-

tained could only be the subject of gratulatory comment.

Our American sanitaria for tuberculosis are attaining as good results in the treatment of the disease as are claimed for similar institutions abroad. What we want now is more of them, and especially more of them so endowed and supported that the poor, and even the indigent, may be able to enjoy their benefits. The removal of large numbers of tuberculous individuals from the ordinary hospitals, and from among the crowded populations of our cities would be of untold service to humanity by limiting the spread of disease. Since the great majority of these patients can, as the statistics of sanitaria show, be returned to their homes after but comparatively short intervals cured or apparently cured, and no longer the source of infected material, the benefit conferred is twofold.

Drs. Brush and Pryor, at the recent meeting of the New York State Medical Society, each showed by calculation of the annual loss to the State because of sickness and death from tuberculosis, that even from an economic standpoint alone, the establishment of State sanitaria for consumptives would be a magnificently profitable investment. But there is, besides the merely sordid view, the great motives of humanity, and the lessening of the present death-rate from consumption which now carries off, despite hygienic precautions and sanitary measures, something more than one-seventh of our population.

The bill providing for the establishment of at least one great State sanitarium in a suitable place in the Adirondacks has been presented to the State Legislature. It thoroughly deserves the effective sympathy and unfaltering cooperation of all who are interested in decreasing the suffering of humanity. It is no new and untried experiment that is to be put into action. The treatment of tuberculosis in sanitaria has forced itself by its results upon the medical profession in the Old World, and the favorite charity of the crowned heads of Europe has become in this last few years the establishment of such institutions for their poor people. Scarcely a State in Europe, however small, but has one of them, and many have a number, and all are planning for new ones, the results of those at present existing having been so satisfactory. Let us hope that the sovereign State of New York will prove as mindful of the wants of her people, and that the proverbial ungratefulness of democracies shall not be exemplified by the inaction of her legislators in so important a matter.

THE SCHOOL DENTIST.

THE School Dentists' Society is an association of dental surgeons in England whose object is to supervise school-children's teeth and see that they are not allowed to decay seriously before receiving proper attention. The *British Medical Journal* remarks that the suggestive statistics it has collected and that have been recently made public in the address of its president, amply justify its existence. As the result of investigation by the school committee appointed by the British Dental Association some years ago, it was announced that the teeth of more than eighty-five per cent. of 10,000 school children of the average age of twelve years needed skilled attention because of premature decay. Similar statistics have been obtained as the result of investigation along other lines.

The School Dentists' Society has been calling parents' attention to these conditions and seems to be arousing parental consciences in the matter. The *British Medical Journal* says that one at least of the large English public schools has taken definite steps toward caring for pupils' teeth. A system has been instituted by which the mouth of every boy is examined at entrance and the actual condition of his teeth charted. A copy of the chart is sent with a note from the head master to the parent or guardian calling attention to pathologic conditions existing and asking that they be remedied before the boy returns for the next term. The charts are kept up to date by subsequent examinations and are filed away for ready reference at any time while the boy is at school. Every Saturday (school holiday) throughout the year a dentist is in attendance to treat such cases as parents desire to have dealt with at school.

This system has been in operation for the past five years and the masters and parents are eminently pleased with the results. The resident medical man writes emphatically of the good that has accrued to the general health of the children and the greater attention paid to this matter by parents. Not the least of the benefits obtained has been "the foster-

ing in each pupil of the (often too dormant) principle of personal dental hygiene with all its attendant and far-reaching advantages."

As the neglect of the teeth in early years often leads to an immense amount of suffering in later life this English idea of dental interest in school children seems a most commendable one. The entrance to the primæ viæ is important too, because of its relations to the digestive tract. The application of the best hygienic principles here cannot fail to benefit greatly the general health. Our American dentists are so well known for enterprise that we are a little surprised to find that they are anticipated by our Anglo-Saxon cousins across the water in a matter like this; we know of no effort that is being made in this direction in this country. The idea of taking care of school-children's teeth is an excellent one. It is next in line for attention, now that the importance of the school physician has come to be generally recognized, and the prevention of the insidious devolopment of pathologic conditions during early years is looked upon as the best pledge of a generation of healthy adults and a vigorous old age.

THE RELATIVE VALUE OF MURMURS AND THE POSITION OF THE APEX-BEAT IN HEART-DISEASE.

NOT long ago in a court of law in a reasonably large town, a doctor on the witness-stand in a suit for damage said that he could very soon tell whether the plaintiff had a heart-lesion or not if he were allowed to *listen* to his heart. The answer is one that is characteristic of most medical men. The generally accepted idea is that a murmur is pathognomonic of heart-disease, and its absence indicative of freedom from disease. There is, of course, the well-known fact that in extremely anemic cases, especially in young people, a systolic murmur may be hemic in origin, but apart from this murmurs and heart-lesions are corelative factors.

One of the best diagnosticians in Europe, especially in thoracic diseases, Professor Gerhardt of Berlin, is known not infrequently to begin a clinical demonstration in this way: "The apex-beat is not displaced, percussion to the right of the sternum shows that the heart-dulness does not extend in that direction. The patient, therefore, either has no heart-lesion, which is extremely probable with the physical signs mentioned, or, if a heart-lesion be present it is not one that the physician need bother his head about; it needs no treatment, in fact, meddlesome treatment would do more harm than good."

There is, in the matter of cardiac diagnosis, an axiom in the internal-medicine clinics at Vienna that comes usually as a distinct surprise to American students who go there. It runs somewhat this way: Be very careful about diagnosing the presence of a valvular heart-lesion unless the apex-beat is displaced. Murmurs may come and murmurs may go, an American with poetical aspirations once said, but the apex-beat has an enduring significance that must not be neglected. Systolic murmurs at the apex without displacement of the apex-beat or accentuation of the second pulmonary sound are phenomena that may be regarded with entire indifference. These may form a large part of the cases in which the murmurs disappear after treatment, and they are published as cases of cured valvular heart-lesions.

The lesson is an important one. Murmurs are at times difficult things to recognize and locate as to time and place; the apex-beat is the most easily recognizable of physical signs, and yet it is of the greatest significance and importance in deciding as to the existence of a heart-lesion and its indications for treatment. There are, of course, the diastolic murmurs that are absolutely pathognomonic of a valvular lesion, but even in the presence of these the position of the apex-beat is of much more importance as far as regards the prognosis and indications for therapy in the case than any nice distinctions as to the character, pitch, and time of the murmur.

THE UNITED STATES ARMY RATION.

So much has been said during the past few months about the manner in which our soldiers were fed during the recent war, and the question of providing food during the next few years for large bodies of troops in distant parts is so important that we have felt called upon to give considerable space to the recent discussion upon this subject at the New York Academy of Medicine.

The discussion was shared in by men who had large practical experience in the recent campaigns of Cuba and Puerto Rico; by men who know also the

nutritional qualities of the United States Army ration and its adaptability to the requirements necessitated by the most varying circumstances of climatic, meteorologic, and telluric conditions. The arraignment, by Majors Seaman and Woodbury, of the army ration as supplied during the recent war would seem to be amply justified by the almost universal experience with it as a source of intestinal, and mental, irritation. Old regular army officers, however, insist that this was not due to the army ration itself, which has been finally adopted after a great deal of study and practical experience, but to the failure of the transportation department to carry all that was committed to it. Commanding officers can, under ordinary circumstances, so vary the diet of their men by drawing alternates for certain articles and by supplying from the company fund things easily obtainable in the country where they are, that there need be no complaint of want of variety. In fact troops have been successfully maintained upon the present army rations during many years both in the bitter winters of Dakota and in the enervating heat of Texas. The real difficulty seems to lie not in any actual deficiency in the army ration itself, but in the failure to properly provide and prepare it.

Too much dependence was placed on precedent in the management of army affairs; too much confidence on the results of the practical experience of the Civil War. There was a clinging to antiquated methods that has resulted seriously. Let us hope that the dearly bought lesson will not be without avail in the colonial military experience upon which we are about to enter.

ECHOES AND NEWS.

Appointment at the Chicago Clinical School.—Dr. J. R. Pennington has accepted the Professorship of Rectal Diseases in the Chicago Clinical School, formerly the West Side Post-Graduate and Policlinic.

Congress Accepts Dr. White's Gift.—On February 17th the Senate at Washington passed a joint resolution accepting from Dr. Octavius A. White of 1011 Madison avenue, New York City, three famous historical paintings as a gift in pious remembrance of his father, John Blake White, the artist.

A Physician's Gift.—Dr. Edward Murphy of New Harmony, Ind., has given $42,000 for the town's public library. Several years ago he provided $30,000 for the erection of the library building. The doctor is eighty-six years old, and desires, he says, "To dispose of my property without the intervention of courts and juries."

Nurses for Consumptives.—The Rev. Father James O. S. Huntington, Superior of the Order of the Holy Cross, a congregation of celibates in the Episcopal Church, having their mother-house at Westminster, Md., proposes the establishment of a new religious sisterhood, whose life-work would be to nurse consumptive patients.

Resolutions upon the Death of Dr. McGillicuddy.—At a recent meeting of the Faculty of the N. Y. School of Clinical Medicine resolutions were adopted expressing the great loss sustained by the School in the death of their esteemed colleague, as well as by the community at large in the demise of one of its most useful citizens and a representative medical man.

The Health Department, City of New York.—For the week ending February 11, 1899, there were reported 170 cases of measles with 12 deaths, 186 cases of diphtheria with 34 deaths, 16 cases of laryngeal diphtheria (croup) with 5 deaths, 181 cases of scarlet fever with 13 deaths, 1 case of smallpox with no deaths, 35 cases of chicken-pox with no deaths, 252 cases of tuberculosis with 160 deaths, and 11 cases of typhoid fever with 5 deaths.

Dr. Cushman Resigns.—Dr. William F. Cushman, for many years Treasurer of the Board of Trustees of the New York Academy of Medicine, has sent in his resignation because of continued ill health that makes it impossible for him to fulfil the duties of the position any longer. His resignation was accepted at the meeting of the Academy of Medicine on Thursday, February 16th, with regrets at the circumstances that occasion it. His successor, until the next regular election, will be chosen by vote of the members of the Council at their next meeting.

Disease from Telephones.—President Murphy of the New York City Board of Health, believing that telephone transmitters are a means of spreading disease, has ordered inspectors to examine the public telephones. The inspectors will thoroughly cleanse the transmitters and receivers with cotton, which will then be sent to the Bacteriological Department of the Board of Health. Should it be found that telephones are likely to disseminate disease organisms, an order will be issued requiring daily disinfection of the instruments by the telephone companies.

The Health Board's Sales of Antitoxin.—On February 7th a hearing on Assemblyman Collier's bill to repeal that section of the Greater New York Charter which allows the sale by the Health Department of its surplus antitoxin took place before the Assembly Cities Committee. James McKeown, Dr. Love, and H. L. Russell, all of New York City, appeared to advocate the passage of the bill. Mr. Russell declared that the Health Department's dealings in this lymph were so profitable that the health authorities could not be induced to try other methods or other lymphs.

Death During Tooth-Extraction.—On February 5th, at

Meriden, Conn., John E. Smith, aged thirty-five years, and apparently in good health, called on Dr. L. T. Doolittle to have sixteen teeth extracted. Dr. E. W. Delcher was present, and gave chloroform, an amount "not exceeding a teaspoonful." During the extraction of the second tooth the patient collapsed and died. His death was pronounced due to strangulation. It is well to remember that it is never safe to begin operative procedures in chloroform narcosis until the patient is completely anesthetized.

The Medical Society of Seattle, Washington.—At the tenth annual meeting of the King County Medical Society, recently held at Seattle, Washington, the following officers were elected for the ensuing year: Dr. Montgomery Russell, president; Dr. R. W. Schoenle, vice-president; Dr. Wm. L. Ludlow, secretary; Dr. C. B. Ford, treasurer. The stated meetings are held on the third Monday evening of each month. The society has a strong and representative membership among the medical men of the city, the society standing for all that is best in the interests of medical science in a county where such influence is strongly needed.

A New Convalescent Home.—A small convalescent home for women and children has recently been opened in Brooklyn, on Harway avenue, near Gravesend Bay. Although organized and in part supported by some German ladies, it is open to patients of all nationalities as far as accommodations will permit. Admission is upon the recommendation of one of the managers and a physician's certificate. The charge in the small wards is three dollars a week, while five dollars is charged if a patient has a room alone. In certain circumstances a patient is taken free if unable to pay this small amount. Application may be made to the matron, Mrs. V. Hollweg.

Female Nurses in the Army.—A bill has been introduced into the United States Senate providing for the employment of female nurses in the Army, in number not less than one-half of one per cent. of the enlisted men. It authorizes the establishment of a Nursing Commission, composed of the Secretary of War, the General Commanding, the Adjutant-General, the Surgeon-General, and three trained nurses to be selected by the President. This Board is for the general supervision of the service. All nurses employed must be graduates of hospital training-schools. A superintendent is provided at a $3000 salary, and an assistant-superintendent at $2000. The nurses' salary will be $40 a month.

A Scientfic Food Wanted.—The "embalmed-beef" controversy now pending in military circles moves a writer in the New York *Sun* to quote "a noted physician" as stating that "a graham gem and an apple contain every element necessary to the sustenance of the human body." This statement induces the *Sun* correspondent to ask why an army cannot be fed without the danger arising from the use of doubtfully prepared beef. No doubt, rations of the sort mentioned above would meet the approbation of Mr. Richard Harding Davis, who has been, it is said, "in a state of mind" because marshmallows were not served to the troops before Santiago, and because the men in the trenches could not be manicured.

New Editor of the Journal of the American Medical Association.—The Board of Trustees of the American Medical Association met February 17, 1899, at the Sherman House, Chicago, for the express purpose of selecting an editor for the *Journal*. The result of balloting was the unanimous election of Dr. George H. Simmons of Lincoln, Neb., editor of the *Western Medical Review*, Secretary of the Nebraska State Medical Society, and of the Western Surgical and Gynecological Association. The salary of the editor has been increased from $4000 to $5000 per annum, but according to a resolution adopted by the Board, Dr. Simmons is compelled to devote his entire time to the interests of the *Journal*. Dr. Simmons became a member of the Association in 1897. He is a well-trained, well-informed medical journalist, and a racy, vigorous writer. He is also a man of great executive ability, and a good organizer.

Death Probably from Hydrophobia.—Walter McCann, aged twenty-two years, of Newark, N. J., died recently from what was supposed to be hydrophobia. He was bitten in the right leg and in the thumb of the left hand on New-Year's night. Two days later he felt a stinging sensation in his left arm, and, becoming alarmed, consulted a surgeon. The medical attendant did not consider the condition serious; as a matter of precaution, however, he cauterized the wounds. Ten days later, McCann was unable to walk, but was helped to get to the City Hospital where his wounds were cauterized once more. After this a consultation of physicians decided that the case was really one of hydrophobia. A series of paroxysmal seizures set in which gradually became more frequent and severe. A sudden noise, or a draught of air, or even a slight unexpected touch, caused him to writhe and twist in agony. It is said that the sight of water had the same effect. This is popularly considered a pathognomonic sign of hydrophobia, but the sight of water has no direct etiological effect in producing the convulsions. Death was in this case due to exhaustion from the number and severity of the convulsions during the few last days.

Words, Words, Words.—We have been not a little amused and interested at an editorial in the *Medical Era* of Chicago under the above caption. The editor takes certain recent exaggerated claims of our young Philadelphia contemporary as to the number of words it gives its readers for their subscriptions as compared with those given by other medical papers. The *Era* institutes another form of comparison. The matter taken by the *Philadelphia Medical Journal* from other medical papers constitutes 1,081,600 of the 1,927,400 words it furnished its readers for the year, leaving less than 850,-

000 words of original matter supplied during the same period. As pointed out by the *Era*, this is, of course, considerably less than what is given by the MEDICAL NEWS. The whole affair, of course, is a juggling with statistics and word calculations, and the employment of the general methods of the advertising agent rather than a dignified appeal to the profession. It is not *quantity* of medical matter the profession wants. We are deluged with medical printed matter. We have not time to read a quarter of what we would like to read. What the profession wants is matter of special interest to the practitioner, carefully selected and boiled down as much as is consistent with its being properly and easily understood. We bow our acknowledgments to the *Era* for the compliment as to the value of our original matter as compared with our self-laudatory contemporary. We shall continue to give as far as possible what is best and most practical in general medical literature, put in such form as to be interesting and useful to the busy practitioner.

Mortality in New York in 1898.—According to the Bulletin of the State Board of Health for December, the mortality of the State of New York for the year 1898 was 120,972 from all causes; this is 3894 more than in 1897, which was a year of unusually low mortality, the average of seven preceding years. The delayed returns, not reported in the Bulletin, numbered 733, making the death-rate per thousand population 18.10, the average of the past ten years being 18.25. The death-rate of the Maritime district was 20.00 against 18.90 in 1897, there having been about 3500 more deaths; of the other districts there is no material variance from the rate of the previous year. Last year the saving in mortality was in the Metropolis. The infant mortality (under five years) was greater by 2300 than in 1897, though relatively decreased, constituting 30.2 per cent. of the total, against 32.5 last year, and an average of 33.5. The zymotic mortality constituted 13.6 per cent. of the total, against 14.0 last year and an average of 17.5. The decrease is confined to the urban communities, some of the rural districts showing a relative increase over last year. Among zymotic diseases there was an increase in the mortality from cerebrospinal meningitis in all but the Central districts; in typhoid fever in all parts of the State including the Metropolis, amounting to about 450 deaths; in whooping-cough by 300 deaths, the increase being limited to the Eastern districts; and an increase (by 1500) in diarrheal mortality from last year, though not beyond the average. Diphtheria caused 2620 deaths, the fewest of any year on record, being less by 1500 than in 1897 and less than half the average yearly mortality from this cause. Consumption caused 13,000 deaths, which is with slight variation the mortality of every year. There were 2500 deaths from grip which is less than the mortality of either of the eight preceding annual epidemics. Acute respiratory diseases had the average rate of mortality, that of other local diseases showed a moderate increase. The mean average temperature for the year was 48.5 degrees above the normal, and the total rainfall (average of State) 44.5 inches, or four inches above the normal.

SPECIAL ARTICLE.

FOURTEENTH ANNUAL REPORT OF THE ADIRONDACK COTTAGE SANITARIUM.

THE fourteenth annual report of this institution, just issued, is full of evidence of how much can be accomplished for tuberculous patients by treatment in a sanatorium and presents besides an eloquent picture of how much can be done for very deserving people unostentatiously and without appeal to the general public. The total number of "hospital days" at the sanatorium for the past year was 30,912 or 4116 weeks. The total receipts from patients, including $1071.57 received from the Trustees of the Free Bed Fund, were $24.563.91. The running expenses were $32,435.35 or over $7500 more than the receipts from patients, this excess being paid for out of the contributions to the General Fund. The cost per week for each patient was $6.75 or $1.75 more than the regular charge per patient per week which is $5.

The results of treatment were most encouraging. The number of patients treated at the sanatorium during the year was 227 of whom 83 are still at the institution. Of the 144 patients who are the subject of report, 38 were discharged apparently cured, 44 with the disease arrested, 39 improved, 14 unimproved or failed and 6 died; while 3 remained less than a week and do not enter into the therapeutic statistics.

There were 34 patients who remained less than three months and of these 6 were apparently cured, 7 left with disease arrested, 13 were improved, 1 died, and only 3 were unimproved or got worse; 110 patients staid at the sanatorium from three months to over sixteen months, an average of over nine months. These are considered under three heads, incipient, advanced, and far-advanced cases. Of the 36 incipient cases, 27 were apparently cured; in 7 the disease was arrested, 1 was improved and only 1 was not benefited by stay at the sanatorium.

Of 48 advanced cases 9 were apparently cured; in 21 the disease was arrested; 11 were improved and 6 were not benefited, and 1 died.

Of 26 far-advanced cases, in 3 the disease was arrested, 13 were improved, 6 were not benefited, and 4 died.

With these statistics before us, it is interesting to note the definitions of the terms employed by Dr. Trudeau as given by himself in the report.

Incipient.—Cases in which both the physical and rational signs point to but slight local and constitutional involvement.

Advanced.—Cases in which the localized disease process is either extensive or in an advanced stage, or where with a comparatively slight amount of pulmonary involvement the rational signs point to a grave constitutional impairment or to some complication.

Far Advanced.—Cases in which both the rational and physical signs warrant the term.

Apparently Cured.—Cases in which the rational signs of phthisis and the bacilli in the expectoration have been absent for at least three months, or in which there is no expectoration at all; any abnormal physical signs remaining being interpreted as indicative of a healed lesion.

Arrested.—Cases in which cough expectoration and bacilli are still present, but in which all constitutional disturbance has disappeared for several months, the physical signs being interpreted as indicative of a retrogressive or arrested process.

The proof of the hygienic value of sanatorium treatment, besides the fact that it removes the affected individuals as sources of infection from the midst of crowded centers of population, is to be seen especially in the disappearance of bacilli from the sputum. In 99 out of 110 cases bacilli were present on admission; in 33 cases they disappeared not to return. One-third of the power for harm of the tuberculous patients treated was absolutely removed.

Dr. Trudeau is doing a great, good work at the Sanitarium, and deserves the sincerest congratulation for it. The unobtrusive, unostentatious character of the work renders it all the more surely a bit of the sincerest philanthropy. The utter unselfishness that has characterized the directors' management of the institution is known to but few, but highly appreciated by them, and will at some time be a fruitful source of inspiration to sincere philanthropists of the generation to come. It is a sincere pleasure to be able to record that the work continues to be supported by voluntary contributions, and that certain improvements in the plant have been made possible recently. The cottages are to be heated by hot water instead of stoves, as heretofore. This will enable them also to have hot baths. Five of the cottages are already connected with the hot-water system, and have their bath-rooms. A large new cottage has been presented to the Sanitarium by Mrs. A. A. Anderson, and will be ready for occupancy before the end of the winter. It is fully furnished, and combines all the improvements suggested by past experience.

A characteristic trait of the thoroughly practical thoughtfulness so typical of the management of the institution is contained in the following paragraph from the president's report: "As most of the patients coming during the winter months are not supplied with sufficiently warm clothing to enable them to carry out effectively the open-air plan of treatment during the coldest season, the institution has acquired by gift some twenty-five heavy fur coats, which are given out to patients in need of them for a nominal rent, just sufficient to pay for storage and repairs on these most necessary garments."

CORRESPONDENCE.

MASSAGE BY TRAINED NURSES.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—The MEDICAL NEWS in a recent editorial advocates massage by trained nurses, saying that they ought to be able to carry out the instructions of physicians with regard to massage and that they should be trained for this purpose by a competent teacher, even if they have to forego less useful instruction.

Allow me say that physicians themselves ought to know enough about massage to show their nurses what to do in individual cases. How many physicians know anything about the practical application of massage? One who has recently been my patient put it as one in a million. More than that are conversant with massage. A surgeon who has also been my patient said he though that not more than one doctor in five hundred knew anything about the use of massage. This is more nearly correct. And yet almost every physician sets himself up as an authority on this subject without either study, instruction or practice.

How about the teachers of massage? They are usually selected from those who have had scant training and not time enough to show whether they are competent to practise it. Worse that that—at one of the Training Schools for Nurses connected with one of the large hospitals in New York an escaped convict, who was simply an acrobat and knew nothing at all about massage, was employed for a while to give instruction in massage. He soon earned for himself the *sobriquet* of the biggest liar in New York. Not long after that he was succeeded as a teacher in the same place by a graduate from a penitentiary of London whose sole claim to honor was that of having translated part of a French book into bad English and posing as the author. One of the recent medical dictionaries quoted him, his theft, and his bad English. The editor was promptly notified but made no reponse.

Now there is a first-class man in New York who is not only a gentleman but also a physician and masseur of wide repute. I am credibly informed that the profession in New York almost completely ignore him. The unwelcome truth of this whole matter is that the majority of physicians both in this country and abroad endeavor to get the cheapest ignoramuses to rub their richest patients until the patients demand better. Is this the golden rule? I have already dealt with the unpleasant subject at some length in the *Boston Medical and Surgical Journal* of October 8, 1896.

DOUGLAS GRAHAM, M.D.

BOSTON, MASS., January 20, 1899.

A PRONOUNCED CASE OF HYDROPHOBIA.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—I notice in a recent number of the MEDICAL NEWS a request that any one knowing anything about a case of suspected rabies should report the same. By way of introduction, I will say that up to the time of seeing the case I take pleasure in reporting I was very sceptical concerning the existence of this disease. My professors in school nearly all doubted it, and especially the professor of surgery, who openly avowed his belief in the non-existence of hydrophobia. He attributed deaths resulting from the bites of supposedly rabid animals to nervous shock and fright.

Again, during my nine-years' experience as a practitioner just preceding the time of seeing this case and having this teaching always in mind, I never met a doctor of much experience without drawing him out on the question as to whether or not he believed in the existence of this disease. I had never met one who had ever

seen a case, and it is hard to find one to-day who has. They claimed to have invariably found the sufferer to be a hysterical subject, and the case eventually proved to be true hysteria. So I concluded that there was, in fact, no such disease, the medical authorities to the contrary notwithstanding; and when people persisted in rushing to a madstone for the cure of the bite of hydrophobic skunks, I was inclined to smile and say, "What fools these mortals be!" In regard to these skunks, I desire to say right here, after an active experience covering twenty-six years on the Western frontier, that I enter my protest against the belief in the existence of rabies in a skunk (*Mephitis Americana*) which has not the disease as a result of having been bitten by a previously rabid animal. Animals die from this disease very quickly; they do not run about, like these skunks, a perpetual menace to man and beast alike; and dogs, where the *Mephitis Americana* abounds would be rapidly exterminated, and an occasional man or other animal would certainly develop this disease. There seems to be an abiding enmity between the dog and the skunk, and the dog, instead of catching one that had this disease, would have to be caught, for he knows.

During the summer of 1878 Mr. S., about eighty years of age, came to a house where I was stopping to get his dinner. He was then on his way to have a madstone applied to a wound resulting from a dog-bite through his thumb. Learning that I was a young doctor, he asked me what I thought of it and what he should do for it. I answered that the best authorities recommended the immediate excision of the part bitten, or the removal by amputation of the wounded member when this was possible, but since a week had passed since he was bitten this procedure would now be of doubtful efficacy. I reassured him as much as possible by saying that it was very doubtful if there had ever been a case of hydrophobia in America. His wife told me that she and the old man were living alone, and that when the old gentleman went to feed this dog at noon one day, just a week before, the dog had suddenly reared up and had bitten him through his thumb. Immediately thereafter, Mr. S., thinking the dog fierce because of confinement, had loosed him, when the dog at once jumped the fence and took the road toward a small town about a mile away. It was known that he had bitten several animals encountered on the way—dogs, hogs, and cattle—two or three of which had already developed peculiar symptoms, and some of these had died; hence, their determination to test the efficacy of a madstone. I told her that only a small percentage of the animals bitten by rabid dogs ever developed hydrophobia, if there was such a disease, and that I had no more confidence in the efficacy of a so-called madstone than I had in a piece of ordinary sandstone. They went on their way, and several days later I saw them on their return journey. They said that because turpentine had been applied to the bite the madstone would not stick.

I thought no more of the case until a runner came to ask me to visit Mr. S. to see if I could determine what was the matter with him. This was just eighteen days after he was bitten. On arriving at the house I found the patient sitting bolt upright in bed, his face intensely congested and his eyes fairly glaring. They said that he had but little fever, but had peculiar convulsive seizures, which at times nearly choked him to death. He was fairly free from delirium. He was closely hemmed in by a number of country women, whom I with difficulty persuaded to move in order to give him breathing space. I sat and watched several minutes without letting him know I was present, for obvious reasons. I then approached him, spoke to him, counted his pulse (which was eighty, and full), looked at his tongue, and then assured him I had only casually dropped in to see him. Shortly afterward I walked back toward the door a few steps and requested a lady to hand me a cup of water and a saucer. I then stepped out in front of him, and drawing his attention poured the liquid from the cup into the saucer, when he immediately had a most horrible convulsion, which completely frightened me out of my wits, because of its severity and the strange expression on his face. I was absolutely afraid of him, as old and helpless as he was, and moved so that I had one or two women between us. When he recovered from this I waited half an hour, and then regretted the production of a repetition of one of these convulsive seizures by the same process. I then gave a very positive prognosis in the case, saying that I regarded the trouble as hydrophobia, and that the patient would surely die within three days. He succumbed at about 3 A.M. on the twenty-first day after the receipt of the injury. Dr. R., now of Bowie, Tex., entered a protest against my diagnosis, claiming that I had made a mistake, and proving this by the ability of the patient to take liquid nourishment on the very night of dissolution. I assured the people, who officiously came to tell me these things, that one of us was wrong, and the facts in the case, according to our best authorities, and the further fact that the patient died "promptly and on time," as the doctor himself was aware, made it almost positively certain that I was right. I also read from the text-books the assertion that the ingestion of fluids other than water was not always attended by convulsions.

A few years since I lived in the town of Montague, Tex. One night a dog, very evidently mad, visited nearly every residence in town and bit a great many other dogs. The following morning it was pursued and killed, and many of those bitten were also destroyed. At least half a dozen, which were spared at the time, developed rabies later and were killed.

In conclusion, I believe that there is such a disease, and that Mr. S. died from its effects, because, First, he was bitten by an animal which, biting other animals, produced as a result something exactly like hydrophobia. Second, that the man, after a proper period of incubation, developed true rabies and died from the effects of the disease. I believe that there is such a disease, because, First, the dog referred to in the second instance must have had it, for dogs madly fought her when she came in contact with them, and showed no desire to cultivate her acquaintance, although her actions were lascivious in the

extreme. Second, every symptom in her case pointed to the fact that she was mad. She made no noise on being shot, and it took many ordinarily fatal wounds to kill her. Third, other dogs developed symptoms which caused the owners, however much they thought of the dogs, to kill them.

Since it is communicable to dogs and other animals, it must be communicable to man also. There were many people, of course, like Dr. R. in the first instance, who did not and would not believe the trouble rabies.

J. E. STINSON, M.D.

CHICKASHA, I. T., January 30, 1898.

MEDICAL EDUCATION AND STATE BOARD EXAMINATIONS.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—Professor James Finlayson's article on "Medical Education" in the *Edinburgh Medical Journal* (pp. 344-348, October, 1898) comes as a happy message to advocate modern methods of laboratory teaching as opposed to didactic lecturing. To this is added the satisfaction that there has lately sprung into existence in New York City a medical school whose keynote is practical teaching. The medical educational system has happily passed beyond the ermine and purple style of Trousseau, with his unbending dignity and pedantic phraseology. It is the ideal, though unfortunately not always the practice of the growing medical educational class to-day, that the mind is best trained through deductions arrived at by itself and that the duty of the teacher is not to arrange in well-ordered tables, etc., what others have worked out, but to direct the student's mind into these channels, *keeping the conclusions for the student himself to arrive at* and leading him back from by-paths which he is too prone to follow out to a blind ending. In America we are learning that students must come to our medical schools with minds trained to think systematically, but it is a lesson yet to be learned by many institutions, and herein lies the difficulty of adopting the purely practical method of teaching in American schools. It is, however, the right method, and in order to have practical proof of its value the writer is keeping records of the source of early training of members of his classes with the object of drawing, in a few years, conclusions as to the value of thorough mental training prior to beginning medical studies. It is absurd that we should expect to turn out men of international mental force in medicine so long as we attempt to train them in methods of both thought and medicine during four short years. The principles of medicine alone are too profound for untutored minds to grasp and we have passed the time when institutions should be allowed to turn out men who have learned only not to do harm.

Another and very serious condition which must, sooner or later, be met, is the impossible methods of examination employed by the majority of State medical boards, methods unpardonable and long ago abandoned by the European schools. I refer to the examining in four days, morning and afternoon, on subjects which have required four years to master. What is quickly learned is quickly lost. Is it a feat of mental gymnastics we wish to see if the men can perform, or do we wish to ascertain if these candidates are so trained that they will only not do harm but intelligently do good? If the former is sought the present system is admirably adapted to this end, if the latter, it is an acknowledged and absurd failure. There is not a physician to-day who, unless he has pursued surgery or held the position of teacher of anatomy, does not acknowledge that he could not pass an examination upon this subject. The same is true of physiology, chemistry, physics, materia medica, and histology. Why then should not these subjects be passed off at an earlier examination of the Regents instead of allowing them to rob of their legitimate time those more vital subjects of medicine, surgery, obstetrics, gynecology, pathology, and therapeutics? There should, for example, be three or even six examinations instead of one, failure to pass any one of which should debar the candidate from taking the next. In this way the standard could be raised and each subject could be soberly and adequately treated, and there would be acquired such fundamental knowledge that though the detail of the subject may have been forgotten, yet the foundation upon which the details could be readily built would remain. These examinations could be distributed throughout the four years of the medical course.

This is none other than the conjoint system of the Royal Conjoint Examining Board of England, and while we may hesitate to adopt many medical methods of our English brethren, yet in matters of education we must acknowledge that they have solved the problem.

Thus, with the proper medical training before beginning the study of medicine and four thoughtful studious years, interspersed with rigid examinations on a reasonable number of subjects at a time, the graduate would go into the medical world feeling not that he had run a gauntlet the doing of which he could not explain, but that every step of the way has been thoroughly and intelligently taken, and that he is able to compete with the graduates of any institution in the world.

C. N. B. CAMAC, M.D.

NEW YORK CITY, January 31, 1899.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

THE DISGRACEFUL CONDITION OF OUR STREETS—THE AFTERMATH OF THE BLIZZARD—HEALTH-BOARD RESTRICTIONS AS TO MEASLES—PROFESSOR STEPHENS CONVICTED OF ARSON—HOMEOPATHIC SOCIETY MEETING—FIFTIETH ANNIVERSARY OF ST. JOSEPH'S HOSPITAL—PERSONAL NOTES—HEALTH STATISTICS.

PHILADELPHIA, February 21, 1899.

THE newspapers have been teeming with communications relative to the disgraceful condition of our streets which, as a result of the storm, are covered with filth, mud, slush, and heaps of half-melted snow. The Citizens' Municipal Association has entered a formal protest against the signing of contractors' warrants whose business it is to keep the streets clean and a number of business men have formed a committee to lay before the

mayor the matter of this neglect. While the officials claim to be doing all that it is possible to do the seas of mud and slush do not seem to diminish, and it is the same old story of derelict duty and official indifference. Drs. S. Solis-Cohen, Judson Daland, and many other physicians have called attention to the dangers incident to such conditions as prevail, but as usual the warning is unheeded and perhaps the solution of many of our municipal problems, so far as they relate to public health will be found some day after a huge epidemic has awakened us from our stolid indifference and then the day of reckoning for our corrupt and dishonest officials will be a mighty one. The aftermath of the storm with its melting snow and slush, causing sewers to overflow and "backwater," is greatly to be feared, and despite the fact that the health board has again issued notices to boil all drinking-water we may look for a further increase in the number of cases of typhoid.

During the storm the police and fire departments accomplished wonders and many who would otherwise have starved or frozen to death were cared for by the men of these departments. Milk was practically the only food which it was impossible to obtain and for twenty-four hours many suffered from lack of it. The modified milk laboratory was unable to supply its baby customers for thirty-six hours.

The Sanitary Committee, to whom the Board of Health referred the matter, has not yet reached any decision in regard to Dr. Lee's suggestion that measles be included with scarlet fever and other infectious diseases in regard to control by the Board. Dr. Lee reported to the Board that while 114 deaths from scarlet fever were reported last year, there were 234 from measles, and he strongly urged the inclusion of measles in the list of contagious diseases, and especially as serious and permanent sequelæ are so common after the infection.

George H. Stephens, at one time a professor in Lafayette College at Easton, was declared guilty of arson on last Saturday. It will be remembered that he was accused of having set fire to Pardee Hall in December, 1897, when the building was entirely destroyed, causing a loss of about $200,000 to Lafayette College. The burning was done as an act of revenge for fancied wrongs he had suffered at the hands of Dr. Warfield, president of the college, and the plea was made by his friends that his mind was unbalanced. This failed to save him, however, and his conviction later became a matter of course.

The Homeopathic Medical Society of Philadelphia held its February meeting at the Lafayette Hotel, Monday evening, the 20th. A paper was read by Dr. W. G. Steele as to the methods best suited to improve the system, which was discussed by several of the members.

The fiftieth anniversary of the founding of St. Joseph's Hospital will be celebrated with special religious services, and a special contribution on Washington's Birthday. The number of cases treated in the out-patient departments, as well as in the wards, has increased enormously during the past five years at the rate of nearly 1000 cases a year.

Dr. Jacob M. Da Costa, Emeritus Professor of Practice of Medicine at Jefferson Medical College, has been elected a member of the Board of Trustees of the University of Pennsylvania.

The total number of deaths occurring in Philadelphia during the week ending February 18th, as reported at the Health Office, was 527, which is a decrease of 42 from last week, but an increase of 78 over the corresponding period of last year. Of this number 161 occurred among children under five years of age. The total number of new cases of contagious diseases was 351, reported as follows: Diphtheria, 51 cases with 10 deaths; scarlet fever, 13 cases with 1 death; typhoid fever, 287 cases with 38 deaths.

OUR LONDON LETTER.

[From Our Special Correspondent.]

ASININITY OF THE GENERAL MEDICAL COUNCIL—DIVERSITY OF MEDICAL DEGREES IN GREAT BRITAIN—DEATH OF THE NOTED PATHOLOGIST, JOSEPH COATS—LONDON'S PROPOSED NEW WATER-SUPPLY—TO SUPPRESS STREET NOISES.

LONDON, February 11, 1899.

THE medical *cause célèbre* of last week was the verdict of the Queen's Bench in the case of Hunter *vs.* Clare appealed. It will probably be remembered that some months ago the Penal Committee of the General Medical Council brought an action against a Mr. H. K. Hunter for using professional titles which did not legally belong to him. There seems to have been an extraordinary amount of confusion not to say muddle-headedness in the minds of this cumbrous and secret-session star-chamber council as to just what Mr. Hunter was guilty of. At least two members of the council have publicly stated in a special letter to the journals that they were assured that he was an unregistered practitioner practising under that flimsiest of all qualifications, an American degree, and was to be prosecuted accordingly. The mouse which was actually born of the ridiculous mountain, however, was an action accusing him of the awful crime of using the title "physician" upon his door-plate, when he was only an L.S.A. (Licentiate of the Society of Apothecaries) and another *separate one* alleging a similar misuse of the sacred name "surgeon." The judge found him guilty upon the first count and fined him $25, whereupon the second was politely dropped. The Society of Apothecaries righteously indignant appealed the case. The appeal has just been heard and the decision of the lower court as to the question of right affirmed, but the fine cancelled on the ground that Mr. Hunter had used the title innocently and in good faith, believing he had a right to it.

And all this disgraceful fuss over a door-plate! Mr. Hunter was a registered practitioner, fully qualified, and nothing whatever was even suggested against his competence or his honesty. Worst of all, as if to bring the pettiness and meanness of the official mind into full relief, the poor gentleman died just after the verdict had been given against him, with the gratuitous slander of the Penal Committee still resting upon him. Altogether the pro-

fession is thoroughly ashamed of the part it has been made to play in the matter and indignant with the committee for the public disgrace it has brought upon the body which it misrepresents. The episode will add greatly to the already strong feeling of dissatisfaction with both the make-up and the methods of the General Medical Council.

Such ridiculous proceedings could of course only have occurred under the antiquated and intolerably complicated system of medical qualifications in vogue here. There are no less than *nine* different degrees or qualifications which entitle a man to practise medicine in England. Three different "Licentiates of the Royal College of Physicians" (L.R.C.P.) of London, Edinburgh, and Dublin; the same three kinds of membership in the Royal College of Surgeons (M.R.C.S.; M.R.C.S.E.; M.R.C.S.I.) making six in all, then M.B., M.D. and L.S.A. Of all these only M.D. entitles its possessor to the prefix "Dr.," although by courtesy this is extended to Members and Fellows of the College of Physicians, and the last one does not even entitle its owner to style himself "physician and surgeon." What wonder that even the conservative *British Medical Journal* is urging the advisability of a uniform or even simple degree.

The Home Secretary has declined to grant the petition signed by 6000 of the Peculiar People, asking him to modify the sentence of Senior, who was condemned to three-months' imprisonment for allowing his child to die of bronchitis without calling a physician.

The Prince of Wales has announced his intention of being present at the delivery of the Hunterian oration this year at the Royal College of Surgeons and will dine at the College in the evening. The oration is to be delivered by the President of the College, Sir William MacCormac, who attended the Prince after his recent fracture of the patella, and H. R. H.'s presence at the function is interpreted as a graceful expression of his gratitude to both Sir William and the medical profession.

English pathology lost another of its standard-bearers last week, scarcely more than six weeks after the untimely death of Kanthack. Joseph Coats, Professor of Pathology in the University of Glasgow, and well known for his original and valuable work, died at his home in the North after an illness extending over nearly three years. He was fifty-two years old and had devoted his entire medical life to pathology, but had only been pathologist in the University for eight years.

The admirable new scheme of an adequate water-supply for London, from the mountains of Wales, is being pushed vigorously by the County Council. Vitally important for the public health as the change is acknowledged to be on all hands, the present water companies are fighting it tooth and nail, even stooping to such ludicrously contemptible methods as sending a swarm of agents into the districts which are likely to be bought up for water-basins to stir up the farmers and peasantry against the scheme and rake up cases of defect or mistake in the notices issued to landowners by the County Council. In this the notorious multiplicity of the John Joneses, the Evan Evanses, and the Ap. Morgans in Taffyland has aided them greatly and the council has had several notices of illegal procedure brought against it on the trifling ground that its original papers were served upon the wrong Owen Owens. The "Water-Lords" have also brought scores of the farmers up to London to protest before the County Council, but as the eagle-eyed reporters have discovered that they are being entertained royally and given passes to the theaters, etc., their formal "opposition" excites more laughter than anything else. In fact the ridiculous scheme has recoiled on its inventors and the latter have not hindered the great sanitary reform in the slightest by their selfish and contemptible maneuvers.

From various quarters in London are coming urgent demands for the physical inspection at regular and frequent intervals of the children in public schools by a physician. This is demanded both as a safeguard against infection, parasites, etc., and also as a means of detecting defects of sight or hearing and of deciding whether children are in proper physical condition for their work. In a few school districts medical men have volunteered their services to the School Board and the results have been so good already that there is a demand for the appointment of regular school-physicians. In Belgium the children are rapidly but carefully inspected every ten days and the system works admirably. Here is another opening for our overcrowded profession.

The *Spectator* and several other papers are having an animated discussion as to whether "catching cold" is not really an infection and the wise men among the laity are rushing into the fray with great enthusiasm. The infectionists have rather the best of it so far, as they can cite the complete freedom from "colds" of Nansen's party in the Polar ice and their prompt epidemic of coryza on return to civilization and the curious "strangers' cold" at St. Kitts which sets half the inhabitants to sneezing every time a ship touches at the port and for weeks afterward. Moreover, as one of them acutely points out "colds" are almost invariably caught in churches, theaters, railway carriages, etc., where bad air and microbes abound and seldom in the open country or when camping out.

The London Society for the Suppression of Street Nuisances held its annual meeting last week and its principal onslaught was directed against the horrible noises which make the streets a Bedlam. The church bells, the muffin bell, the cries of hawkers, and above all the organ as she is ground were inveighed against and it was darkly intimated that this fiendish concatenation of sounds was what was really driving the workingman to drink. Fully half the noise in the city streets is idiotically unnecessary and should be stopped in the interests of both comfort and health. The dawning of a better day is already in sight for a woman in East Westminster has just been fined under the new Public Nuisances Act for keeping a crowing cockerel which would disturb the neighbors in their beauty sleep. If only the midnight cat can be brought within the operation of the Act we may hope to rest in peace.

The use of "dust destructors" on the furnace plan is spreading rapidly in England. Many of the provincial

towns have them in successful operation and several of the London districts as well. They consume street sweepings, factory refuse, house and stable litter, everything in fact that is too solid or bulky to go down the sewers. In one London destructor not only is the dust and refuse destroyed and the smoke therefrom consumed but enough heat generated to run the parish dynamo for electric-lighting. We have got past "dust to dust" and "dust to electric light" seems the revised version.

The *British Medical Journal* recently published a letter from a medical missionary in China, in which he states that the infamous custom of compressing ladies' feet is frequently productive of necrosis of the metatarsals, ulcers and fistula. He has treated a number of these women by removal of sequestra, curetting, and packing with gauze.

BLACK-WATER FEVER—RECOVERING FROM A BROKEN NECK—ON THE CHOICE OF ANESTHETICS—FOUR INTERESTING CASES OF PERFORATION OF A ROUND ULCER—AN INSTRUMENT FOR CRUSHING AND WASHING OUT GALL-STONES — TREATMENT OF STRICTURE OF THE ESOPHAGUS FROM BELOW UPWARD—SUDDEN DEATH AFTER PARTURITION—AORTIC ANEURISM DOES NOT CAUSE HYPERTROPHY OF THE HEART—NATURAL RESULT OF ADHESIONS OF SEROUS SURFACES.

AT the Pathological Society of London, December 20th, CROSSE and PACKES reported a case of black-water fever which occurred in a young officer who had served fourteen months in Nigeria. The attack began apparently as an ordinary attack of malaria, but after two days the symptoms of black-water fever appeared. There were pyrexia, jaundice, green vomit, and hemoglobinuria, and a slight amount of albumin in the urine. The blood contained hematozoa of the estivo-autumnal type. The patient improved after the administration of quinin but had a relapse a few days later. The quinin was increased in quantity and the relapse was quickly recovered from. As the symptoms of black-water fever came on in this patient six hours before he received quinin the theory that black-water fever can be caused by quinin must be laid aside. Two other theories are possible: One is that the disease has no connection with malaria, and the other is that the disease is a complication of tropical malaria. If the first alternative is true it must be admitted that the disease can develop in England or can have a latent period of more than four weeks as the patient had left Africa more than a month before his symptoms developed. The speakers were inclined to regard black-water fever as a complication of malaria since it attacks only those persons who have had malaria in a tropical climate.

At the session of January 17th POTTER showed the cervical vertebræ of a man who died of old age at the age of eighty-two years. The interesting point was that he had received a blow from a falling wall twenty years previously. His head was forcibly flexed on his chest and he was unconscious for two days. There was loss of power of the right arm and leg. He was kept in bed with his head fixed for four months and ultimately recovered entirely, though there always remained a prominence at the back of the neck and the chin almost touched the sternum. Section of the spine showed that the cervical vertebræ had been crushed together, and the second, third, and fourth were at right angles to the lower three. Compression of the bodies of the vertebræ seemed to have saved the cord from stretching.

At the Society of Anesthetists, December 16th, WHITE discussed the choice of an anesthetic. Upon etherized patients reflex shock due to the operation does not appear. This is not true of chloroform. Prolonging an operation under an anesthetic is to be deprecated. While children and the aged take chloroform better than the adult, still children sometimes succumb to it. Ether, if carefully given, is well borne by children. He regarded advanced age, independent of lung disease, as no insuperable objection to ether. In chronic lung troubles he used ether if possible, but chloroform for acute pulmonary troubles. In cardiac disease, save in aneurisms, ether was his choice. In abdominal surgery he used ether, giving it very lightly. In brain surgery he preferred chloroform with or without morphin. For operations about the mouth he commenced with gas or ether to stimulate and alleviate shock and then changed to chloroform.

SILK agreed with some of the points of the speaker but advocated the A. C. E. mixture for operations upon children between the ages of three and twelve, and for adults over sixty; also in very stout persons or those affected with chronic pulmonary or renal troubles. He also used this mixture in operations upon the head and neck.

At the Glasgow Medico-Chirurgical Society, December 16th, STEVEN showed specimens from two cases of perforating ulcer, one of the duodenum and the other of the stomach. Both patients were young women who were attacked, while engaged in their duties, with intense epigastric pain. The former died in collapse in twenty-four hours; but the latter rallied the first day, and went about her work, but a second attack of pain occurred one day after the first one, and in forty-eight hours she was dead. There was general peritonitis in both cases. Steven thought that the first attack of pain in the latter patient was due to a partial rupture of the ulcer, the second attack to its complete perforation.

RUTHERFORD mentioned a case of perforating ulcer in the stomach in a girl, aged twenty-five, in which the diagnosis was promptly made and the ulcer sutured within eight hours of the attack of pain. The patient did well for a time, but died three weeks later of general peritonitis. There were many old adhesions, and at the autopsy there was found a second ulcer in the posterior wall of the stomach, which had also perforated.

At the Birmingham Branch of the British Medical Association, November 25th, SHORT showed the stomach of a girl, aged sixteen, who was first seen fourteen days after an attack of epigastric pain and vomiting. She had had pain after meals for a year previous, but had never vomited blood. The physical signs pointed to air and

fluid beneath the diaphragm. On draining the cavity through the ninth space in the posterior axillary line fetid pus was evacuated. She did very well for some three months, but the temperature was never satisfactory. At the end of this time she suddenly developed acute pleuropneumonia of the right side and died in a few days. At the necropsy some curdy pus was found in the crevices between the stomach, liver, and diaphragm; otherwise the abscess cavity was healed, and the ulcer closed by firm adhesions to the spleen.

At the meeting of December 8th TAIT showed an instrument which he had repeatedly used with success in breaking up concretions left in the ducts after cholecystotomy. He found that wherever a stone had traveled this instrument would follow without risk. It consisted of a small scoop, out of the end of which was cut a notch so that an instrument after the fashion of a double-quill drill was formed. The addition of a tubular handle through which a stream of water was forced greatly assisted in the removal of the *débris*. The success met with by Mr. Barling and others in freely laying open the ducts and removing the stones entire was alike gratifying and surprising, but, for his own part, he would feel safer in leaving the ducts intact.

BARLING showed a patient, aged two years, who had swallowed sulphuric acid and acquired a stricture of the esophagus. Frequent attempts were made during the next two months to pass bougies through the stricture, but they all failed, even under an anesthetic. The stomach was, therefore, opened, and a fine bougie was passed from below upward, and a string was drawn through. By means of this string the stricture was sawed until it would admit a No. 13 bougie. This was left *in situ*, one end being brought out of the mouth. The incisions in the stomach and abdominal wall were both closed. The after treatment consisted in the daily passage of a No. 16 bougie. There was still a great tendency to contraction, but the child was improving in general health and able to take solid food of all sorts.

At the Liverpool Medical Institution, December 15th, CAMPBELL reported a sudden death occurring twelve days after parturition. The patient was a primipara, aged forty. The perineum was torn and sutured, and it healed by first intention. There was insomnia for four days. The temperature never exceeded 100° F. On the seventh day there was slight twitching of the muscles of the face and limbs, followed by a brief period of unconsciousness. On the twelfth day the patient died suddenly while taking a cup of tea. The only pathological condition found at autopsy was a thrombosis of the basilic artery. Many cases of sudden death ten to fourteen days after labor have been without autopsy ascribed to pulmonary thrombus.

At a meeting of the Royal Medical and Chirurgical Society, January 10th, CALVERT read a paper on "Aortic Aneurism as a Cause of Hypertrophy of the Left Ventricle." A search through the records of St. Bartholomew's Hospital for the last thirty years showed that autopsies had been performed upon 124 subjects who had aneurism of the arch of the aorta. In 68 cases there was no hypertrophy of the left ventricle, while the hypertrophy could be perfectly explained by other causes in 47 of the remaining cases, and could probably be so explained in the remaining 9 others. There was, therefore, no evidence in these pathologic records that aneurism of the aorta causes hypertrophy of the left ventricle.

LAZARUS BARLOW said that the records of St. George's Hospital for the past two years bear out Calvert's statement. In eight out of thirteen cases of aneurism of the ascending or transverse arch of the aorta, it was expressly stated that no hypertrophy was present. In the remaining five cases the hypertrophy was accounted for by aortic regurgitation or granular kidney.

At the Harveian Society of London, January 5th, MARSH read a paper on the "Subsequent History of Cases in Which Adhesions Have Formed in the Joints, Peritoneal Cavity, and Elsewhere." Adhesions, if not too extensive, tend to become absorbed. He mentioned a typical case of a middle-aged woman who, after peri-uterine inflammation, suffered so much pain that an exploratory laparotomy was performed. The intestinal coils were firmly matted together, and nothing was attempted. Two years later the abdomen was again opened in order to remove an ovarian cyst. It was observed that almost every trace of adhesions had passed away. The natural tendency to the absorption of adhesions gives the key to the treatment of many joints. Cases of adhesion in joints should be divided into three classes: In the first group are placed those cases of adhesions due to an inflammation neither severe nor prolonged. Such adhesions soon disappear spontaneously. If the inflammation has been more severe or prolonged the adhesions are so extensive and firm that they will not disappear of themselves. The treatment should be to break up the adhesions under an anesthetic, and to follow this with passive motion and massage. In the third group are the cases in which long acute inflammation has destroyed the joint surfaces, and the joint is practically converted into a scar. To break up the scar tissue is useless, as it will simply form again. In the great majority of tuberculous cases, at whatever stage, manipulation is not advisable, nor even safe.

MANDERS remarked that the cases of light inflammation which Marsh had spoken of were really not inflammatory at all, but simply instances of traumatism. Adhesive inflammation due to microbic infection is a totally different condition, in which attempts at manipulation always fail. He explained this on the theory that the toxins dissolved the endothelium of the joint.

For Fetid Breath. — BAYER thinks that chronic nasopharyngeal affections are the principal etiologic factors in this condition. In women who suffer from it at their menstrual periods congestion and increased secretion of the nasopharynx can be demonstrated. The trachea is usually affected as well. When the diagnosis is made secure by examination, Bayer recommends intratracheal injections of carbonate of creosote, using 8 to 16 minims of a fifty-per-cent. solution, slightly warmed, in an intralaryngeal syringe. There is no irritation produced, and the result gained is most satisfactory.

SOCIETY PROCEEDINGS.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held Thursday Evening, February 2, 1899.

THE President of the Academy, DR. WILLIAM H. THOMSON, in the Chair.

The paper of the evening was read by DR. LOUIS LIVINGSTON SEAMAN, Surgeon-Major of the United States Volunteer Engineers, and its subject was

THE UNITED STATES ARMY RATION AND ITS ADAPTABILITY FOR USE IN TROPICAL CLIMATES.

Dr. Seaman considers that the matter of diet for our army in the new conditions which recent events have created for it is one of the first and most important things to be thought of. English reports of the difficulties encountered by their armies in tropical climates declare that the ill health of the soldier is due to three factors—unsuitable eating, drinking, and clothing. Some even claim that the effect of the climate itself is secondary to these. We are about to enter on a period when United States soldiers may be called upon to serve under the greatest extremes of climate. Take for instance, the most recent weather reports obtainable as to the state of the temperature in various parts of our domain in these last few days. In Alaska 50° below zero, in Santiago 80° above, in Manila 90°, in Havana 104° above zero. It is evident that a very different provision for diet and clothing is necessary in these various places with a temperature difference amounting to 154°. If two ships are being fitted out, one for an equatorial, the other for an Arctic voyage, it is evident that they must be provisioned and provided for in other ways quite differently, yet the law directs that the army serving under these different climatic conditions should have the same rations. Physiologically, we know that a diet full of nitrogen is proper for the North, but will be overheating and irritative at the South.

The United States army daily ration is as follows: Fresh beef 20 oz., or salt beef 22 oz., or bacon, or pork 12 oz.; bread 18 oz., potatoes 16 oz., peas, or beans 2.40 oz., or tomatoes 5 oz.; rice 1.60 oz., sugar 2.50 oz., coffee 1.60 oz., and salt 1.25 oz. It is clear that the ration thus outlined is entirely unsuitable for tropical climates. Much more vegetables and much less meat are required. There is in hot climates very little craving for meat. Nature in each zone supplies the products which are most suitable for animal consumption in the special region. At the frozen north where heat-supplying food is the main need, there are no vegetables to speak of, and the animals are clothed by Nature with a covering of fat that makes their meat, when used as food, especially calculated to produce heat. In the tropics Nature supplies an abundance of vegetables and fruit that are satisfactorily nutritive, but are not heating, while in the temperate zone there is the proper mixture of these dietetic elements that is suitable for the midway character of the climate, and its calls for heat-producing materials. Nature has even provided in the different seasons in the temperate zones the food most suitable for each one. Young green vegetables in the spring time when much heat is not needed as an adjunct to the animal diet of the winter time, vegetables and fruits in abundance in the summer and autumn when nutrition but not heat is most needed by the system; while she provides an exclusively animal diet in the winter time.

The British have realized this in India, and have supplied the common soldier with one-fourth less meat and one-fourth more vegetables when serving under the Indian sun. Tommy Atkins is the greatest meat-eater in the world, but he has taken kindly to the change realizing that it is for his good. Even with this reduced amount of meat, however, army inspectors declare that too much meat is consumed for the health of the soldier in India.

Our own trouble in the tropics at Santiago and in Puerto Rico, during the late campaign, was not any lack of food in quantity, though the emaciated appearance of our soldiers on their return led to many false stories to this effect, but was due to a mistake in the quality of the food furnished us. More than one-half the regiment was under the weather in a week with symptoms of gastro-intestinal irritation. To the intense relaxation produced by the hot moist climate, there was added the constant irritation of an extremely unsuitable diet,—fat salt meat, tinned beans and tomatoes that had began to ferment. Resistive vitality was lowered, hyperemia, and incipient inflammatory conditions of the intestinal mucosa set up by irritation, and the intestine prepared for the successful invasion of pathogenic micro-organisms. It is probable that with the body juices in normal condition and the intestines not so predisposed to infection by irritation most of the soldiers would have escaped the typhoid epidemic, despite the almost universal prevalence of its specific bacillus. Could there have been a change of rations when the irritative intestinal conditions were first observed most of the after sickness would have been avoided. As it was we owed whatever alleviation we had in this matter to the thoughtful munificence of private individuals who, for two months, supplied us with fresh milk, and to the generous supplies of the Red-Cross people that proved a veritable blessing.

There was no lack of drugs, though this has often been said in the newspapers, at least, none that I saw. What was needed was not drugs but diet. Hospitals got best results that were able to give an absolute milk diet as I have shown in an open letter in this month's *Century*. Besides this dietary treatment one other thing would have saved life, the preparation of the soldier for his experience in the tropics by a diet, for some time before, suitable for the climate he would have to endure.

There was a striking similarity, clinically, about all the cases of intestinal disease, and the autopsy revealed a striking uniformity of lesions. A congested liver, a hyperemic intestinal mucosa, covered with a pale tenacious mucus, and congested Peyers' patches that were often prominent and inflamed looking. Nothing specific, however, above all no ulcerative lesions of Peyers' patches pointing to typhoid. This confirmed the clinical diagno-

sis and the negative Widal reaction in these cases. We were almost as much at a loss for the immediate cause of death after the autopsy as before it. We seemed to be in the presence of a new undescribed form of intestinal disease. The etiology of it was not some new microbe with a long scientific name, but a salt-fat-meat-pork-hard-tack-dried-bean-diet in a tropical clime.

Salt-meat rations are, in English experience, extremely liable to cause intestinal trouble. In the first Burmese War one-half of the soldiers who made the campaign fell victims. In other parts of the Indian service as many as 700 out of 900 have been known to be on the sick-list as the result of unsuitable diet. Not only salt meat but an excess of fresh meat will have the same result. Laveran tells us that in Northern Africa attacks of intestinal trouble among the men could often be connected with stolen mutton.

It is plain then that the present United States Army ration must be modified to be made suitable for our men when on service in the tropics. Even the non-meat portions of it are unsuitable. The canned and dried beans are objectionable because they so easily cause irritative fermentation processes in the intestine in hot weather. Nearly every issue of them was followed at Santiago by a marked increase of diarrhea. It was very different with the small dark native bean, the *frijole*, which proved easily digestible. Canned tomatoes were also unsuitable, and they do not replace as they are claimed to do the fresh tomatoes, which are besides plentiful and easily obtained.

The requisites of an army ration are that it should be non-irritating and easily digestible and then should be easily portable. These conditions the present ration does not fulfil. The new ration should be more flexible than the present one seems to be. At present there is too much meat allowed. We are far ahead of other countries as to the meat ration allowed our soldiers. The German soldier, the best trained fighting machine in the world, gets but 5⅓ oz. of fresh meat, or 4⅖ oz. of salt meat daily, but makes up for it by getting 79 oz. of vegetables. He gets only one-fourth as much meat, but more than double the amount of vegetables supplied to our soldiers. The Russian soldier gets 7 oz. of meat and 48 oz. of vegetables. The Italian, 7 oz. of meat and 37 oz. of vegetables. The Belgian, 8 oz. of meat and 61 oz. of vegetables. It is evident then that a change must come in the direction of reduction in the meat supplied and increase of the vegetables.

The beef and salt meat might, with advantage, be cut down one-half and farinaceous foods added to supply their places. The meat should be procured fresh from local sources, or if it has to be shipped should be shipped unkilled. This is not a difficult matter, and there is no other way to save loss and prevent illness from the consumption of a tainted meat, since refrigerator beef spoils with extreme rapidity as soon as removed from cold-storage in the tropics. Cereals should be added to the diet, especially hominy, and the present allowance of rice should be at least quadrupled. The hardy Japanese soldiers live almost exclusively on rice. The Greeks were magnificent soldiers and yet lived to a large extent on lentil soup. The spirit of Leonidas' little band of Spartans despite this meager diet shows that valor is not solely a function of commissary beef. One very important matter besides the diet is its preparation. No food, however good or suitable but can be spoiled in the cooking. The Lord made good food and the devil made bad cooks. Inefficient incompetent cooks were responsible for a good deal of sickness. The Government should establish schools for camp cooks. No measure would do more for our army in the tropics than this.

I have gone into this subject somewhat in detail because the last report of the army inspectors says there is no improvement in the United States Army ration that can be suggested as the result of recent experience. I venture to think that certain things need to be improved, and that the method of the improvement is not far to seek.

DISCUSSION.

MAJOR J. M. G. WOODBURY said he thought that Major Seaman had the very right end of a very good stick. and was perfectly justified in using it as he did. He had not overestimated the causes he deemed he saw at work, and he was not rash in stating his conclusions. It is perfectly clear that our present ration will not do in the tropics. The suggestions as to hominy, rice, and vegetables are excellent, and are thoroughly in accordance with the results of his own observations, and these articles may be transported practically as easily as those now supplied.

As to the cooking, very often in our late war it was unspeakably bad, and even that wonderfully accommodative subject, the United States Army Volunteer, was unequal to it. Major Woodbury then described very humorously some of his experiences in performing his duty as inspector, and especially in the cooks' department. Among the regulars in the cooks' realm he found every thing in excellent order, tins clean and scoured, materials well protected from dampness and insects, and a suitable place for everything. Among the volunteers, as a rule, he found everything just the opposite. Accumulations of grease on the inside of vessels, soot on the outside, flour allowed to become damp and ferment, vegetables unprotected from flies and insects, and very little attempt at order. Uncleanliness in the cooks' department was responsible for a large share in the difference of morbidity among the regulars and the volunteers. This was an important item since, under his own observation, while but twelve per cent. of the regulars were sick from twenty-five to thirty per cent. of the volunteers were laid up.

COLONEL WOODRUFF said that with much of Major Seaman's address he was in accord. The difficulty was not, however, with the ration. The United States Army ration was not as had been claimed an iron rule admitting of no exceptions, least of all did it consist of only the list that had been discussed this evening. There were a hundred things nearly that might be drawn by commanders, as alternates for the articles mentioned. The list as given was only meant to be a general guide

as to the things usually required, and the amount of money allowed by the Government to be spent daily for each soldier. To those who knew its possibilities the United States Army ration was most flexible. This was why the decision had been made that there was no suggestion to offer for its improvement. Experience would show that it was sufficiently flexible even to be made suitable for troops in the tropics.

MAJOR KILLBOURK said that army men had been treated to so little of the army ration in Cuba and so much of it in the daily papers since their return, that their feelings were in quite a whirl. The trouble in Cuba was not quality of food but quantity, *i.e.*, insufficiency of food and that not due to the fact that insufficent food was supplied by the Government, but that transportation could not be secured to bring it to the men. As to all diet the great question is its adaptability to the individual and the individual's personal equation as to foods. He had seen a soldier dying of inanition, though liberally supplied with the hospital's best, appeal for corn-pone to which he had been accustomed at home and proceed to get well on it.

MAJOR BELL said that they lived not on but in spite of their rations at Santiago. Some of the material furnished was most unsuitable. Green coffee was distributed on the fighting-line at San Juan Hill. As a rule too much coffee was drunk. His men were not sick till the rainy season had set in. Some of them craved bacon and salt meat. After the distribution of rations of fresh meat many of them improved. There was a craving for sweets and for rice and hominy that should and could have been satisfied rather easily. Molasses should form a part of the ration at all times.

MAJOR JARVIS said that the Anglo-Saxon was not made for the tropics. He would need a new alimentary canal for that. Farinaceous foods instead of meat did not comprise the answer to the problem. The cellulose in them was irritating. The customs of life among the people made the rations of other countries different from ours. As to our soldiers they demanded meat and all the habits of a lifetime made them crave it, and they must have it. The English have learned the lesson after generations of experience and they are arming their colonists. This is the real solution of the question of keeping an army in the tropics.

Owing to the lateness of the hour Major Seaman in summing up said only that he hoped that the perfectly free discussion of the evening would carry its due weight and that some of the things said might be practically suggestive to those who had the matter in hand.

THERAPEUTIC HINTS.

For Hysteria.

℞ Ac. arseniosi . . . . gr. ss
Ferri sulphatis } aa
Ext. sumbul } aa . . . gr. xx
Asafetidæ . . . . . gr. xl.

M. Ft. pil. No. XX. One pill three times a day after meals.

Treatment of Lupus Vulgaris —UNNA has found the most efficient application for this affection to be butter of antimony, and that its action can be better localized by the simultaneous use of creosote and salicylic acid.

℞ Antimonii chloridi } aa . . . 3 ss
Acidi salicylici }
Creosoti
Ext. cannabis indicæ } aa . . . 3 i
Lanolini . . . . . 3 ii.

M. Sig. External use.

In order to prevent pain from the immediate action of the caustic Unna employs cocain mixed with an inert substance as follows:

℞ Cocain hydrochlorat. . . gr. viii–xvi
Magnesii carb. . . . 3 iiss.

M. Sig. Powder the part, then cover with a layer of moist absorbent cotton, and retain in place fifteen to twenty minutes, using light pressure.

After cocainizing, place a thin coat of the caustic salve on the affected area, and cover with zinc-oxid plaster. The application is renewed after twenty-four to forty-eight hours, according to the amount of secretion. The nodules disappear rapidly, while healthy granulations form.

Treatment of Ulcerative Stomatitis. — TORDENS finds nothing so effective as chlorate of potash internally, which he prescribes as follows:

℞ Potassii chloratis . . . gr. xv–xxx
Syr. aurantii . . . . 3 iiss
Decoct. cinchonæ . . q.s.ad. ℥ ii.

M. Sig. Two teaspoonfuls every two hours.

He recommends, further, a mouth wash of boric acid or sodium benzoate solution, or swabbing with a solution of zinc sulphate, or potassium permanganate, the latter rendering good service in the strength of 1–1000, applied several times a day on absorbent cotton.

Good general hygienic conditions are of course necessary; the food (liquid) should contain albumen and be given cold, as iced milk or cold bouillon, in order to diminish heat and pain in the mouth.

For Exophthalmic Goiter.—DIEULAFOY employs ipecac in most cases as a remedy for the vascular erythism.

℞ Pulv. ipecac. . . . . gr. xxx
Pulv. digitalis fol. . . . gr. xv
Ext. opii . . . . . gr. iv.

M. Ft. pil. No. L. Sig. Two to four pills a day.

The ipecac is never to be pushed to the extent of causing vomiting, but slight nausea is allowable. It is to be continued for at least several months. Valerianate of ammonia may often be given with good effect, and hydrotheraphy is recommended for an indefinite period.

For Lead Colic.—Prescribe 10 grains of potassium iodid to be taken three times a day, followed by a tablespoonful of the mixture here given, according to *Brunton*.

℞ Magnesii sulphat. . . . . ℥ i
Ac. sulphur. dil. . . . . ℥ i.
Aq. dest. . . . . ℥ iv.

M. Sig. One tablespoonful three times a day.

ORIGINAL ARTICLES.

SOME PRACTICAL POINTS IN THE PHYSICS OF STEAM STERILIZATION.[1]

BY THEODORE DUNHAM, M.D.,
OF NEW YORK.

NOTHING that I shall present to-night is particularly new. I invite your attention not to newly found principles but to a property of steam which is too little appreciated by the manufacturers of our sterilizers, and by many of our profession. As a result, much of our apparatus of the most perfect workmanship fails to give the sterilization indicated by the gages and thermometers. I shall say nothing of the bacteriology of sterilization, but confine myself to the physical principles involved in getting an equal temperature throughout a steam sterilizer, the lamentable shortcomings of most sterilizers, owing to lack of recognition of these principles, and the very simple and practical means by which the errors can be avoided.

Let me first state a few facts, and then rehearse a few experiments which demonstrate them: Steam has a much lower specific gravity than air; air is a poor conductor of heat; air will not condense except at an extraordinarily low temperature and high pressure. Steam will condense at once on coming in contact with a cooler body, and give up its latent heat to that body. This makes it a perfect vehicle for conveying heat. The lack of this quality of condensation makes air an extremely poor vehicle for conveying heat.

When sterilization is about to begin in a sterilizer, the sterilizer contains, besides the objects to be sterilized, air. If the temperature in the sterilizer is to be made the same in every part of it, within a reasonable time, the air must be entirely got rid of and replaced by steam. Owing to the great difference in specific gravity between steam and air the air will be soonest got rid of if due regard is paid to this difference of specific gravity.

Let me now rehearse my experiments: For the first series of experiments I constructed a cylinder of tin two feet nine inches high and six inches in diameter. It had four openings for thermometers, placed one above the other at intervals of nine inches. These openings received thermometers through rubber stoppers. At the top and bottom were two more openings, provided with perforated stoppers carrying glass tubes. The apparatus was suspended vertically. The steam used was generated in a tin can over a gas flame. The same amount of flame was used in all the experiments. In describing the experiments the uppermost thermometers will be designated *a*, the others, in order from above down, *b*, *c*, and *d*. Readings were begun and time taken when any thermometer reached 40° Centigrade.

Experiment I.—Steam was introduced at the *top*, and the glass tube at the bottom served as the only vent. In 1 minute *a* rose from 40° to 82° C. In 1½ minutes *b* was at 40° and 30 seconds later had risen to 89° C. In 3¼ minutes *c* was at 40° and 30 seconds later had risen to 96° C. In 4¾ minutes *d* was at 40° and 30 seconds later had risen to 78° C. At the end of 9 minutes all four thermometers stood at 99° Centigrade and remained there. A moment later steam began to issue from the vent at the bottom.

Experiment II. — Steam was introduced at the *bottom*, and the tube at the top served as the only vent; *d* first indicated 40° C. and then, at very short intervals, *c*, *b*, and *a*. At the end of one minute all had reached 40° C. They all rose together, and at any given moment registered almost exactly the same temperature. As the temperature got higher the differences became less and less. At the end of 36 minutes all four thermometers stood at 99° C. and remained there.

Experiment III.—The upper opening was closed. A stopper with two holes was placed in the opening at the bottom. Steam was introduced through one opening, and the only vent was through the other. All four thermometers reached 40° C. within one minute of each other. They rose with almost perfect equality. At the end of 32 minutes all had reached 99° C. and remained there.

Experiment IV.—The opening at the bottom was closed. A stopper with two holes was placed in the upper opening. Steam was introduced through one opening and the only vent was through the other. Thermometer *a* was the first to reach 40° C. One minute later it had run up to 90° C. *B* stood at 40° C. and one minute later had run up to 90° C. In 6½ minutes *c* stood at 40° C. and went slowly up. In 20 minutes *d* stood at 40° C. and went very slowly up. At the end of an hour *a* and *b* both stood at 99¼° C.

[1] Read before the Harvard Medical Society of New York, January 7, 1899. For discussion, see page 285.

c at 99° C., and *d* at 73° C. With this arrangement of inlet and vent the replacement of air by steam was evidently extremely slow in the lower part.

The above four experiments show conclusively that the quicker the air is eliminated and replaced by steam the faster the temperature will reach the maximum for saturated steam at the given pressure (in this case, the atmospheric pressure), and that this will be quickest accomplished when gravity acts to the best advantage.

With the inlet above and outlet below the air could freely flow out and suffer the least possible dilution with the steam which entered above. The thermometers rose serially from above down, and with a sudden run of the mercury as the bulbs were left by the falling air and enveloped in the descending column of steam. Only air escaped below until the thermometers were all high. In 9 minutes they all registered 99° C.

In Experiment II. the steam entering below and the vent being above the steam swirled up through the cylinder and a mixture of steam and air escaped from the vent. The mixture of steam and air must have been nearly uniform throughout for the temperatures advanced almost simultaneously. The air was expelled by fractional dilution and only at the end of 36 minutes did all the thermometers stand at 99° C.—four times as long as it took in Experiment I.

In Experiment III. the inlet and vent were both below. The steam swirled up making a nearly uniform mixture with the air and the thermometers kept close together throughout. The air was expelled as in the last case by progressive dilution; but here, the vent being below, gravity assisted, and all thermometers registered 99° C. in 32 minutes — 4 minutes sooner than when the vent was at the top.

In Experiment IV., both inlet and vent being above, gravity had no influence whatever in expelling the air. Only the progressive dilution from diffusion and conversion was operative. The upper two thermometers rose quickly, but at the end of an hour the lowest thermometer stood at only 73° C.

The experiments show that in a sterilizer the steam should enter at the highest point, and the air find its exit at the lowest point.

A second set of experiments I made with a pressure-sterilizer at a pressure of 20 pounds. To take the temperature in the bottom of the sterilizer a hole was bored through the head of the sterilizer, and a thermometer so placed that its bulb, protected by a glass covering, was within the sterilizing-chamber very close to the bottom. The stem projected outside and could be read. Owing to conduction of heat by the metal casing, etc., this thermometer did not give the full temperature of the atmosphere about its bulb. The highest temperature it would record at 20 pounds was 122° C. But for this investigation the relative temperatures under various conditions were sufficiently striking to demonstrate the principles involved.

The sterilizer was of the Sprague pattern, made by the Kny-Scheerer Co. It consists of an inner cylinder for the materials to be sterilized and an outer cylinder enclosing the first. The space between the two serves as the boiler, and the steam can be let into the inner one by opening a valve. The apparatus was originally provided with an ejector, the vacuum pipe of which communicated with the top of the sterilizing-chamber. This was charged so as to draw from the bottom of the chamber.

Experiment I.—Steam at 20 pounds was let in and the pressure maintained at 20 pounds. At the end of 5 minutes the thermometer stood at 96½° C. At the end of 30 minutes it had reached only 104° C. I then opened an air-cock at the bottom of the sterilizer and let all the air out. In 3 minutes all the air had been expelled and the air-cock was closed. The pressure had fallen to 10 pounds and yet the mercury had risen from 7½° to 11½° C. The pressure was than allowed to rise to 20 pounds, which it did in 8 minutes. The mercury then stood at 122° C. I measured the air which was blown off through the cock, and it was much less than one-half the capacity of the sterilizer. Unless so much had escaped by leaks in the sterilizer the temperature would probably not have reached even 104° C. in the 30 minutes.

Experiment II.—The air was got rid of as quickly as possible. With the pressure at 20 pounds in the sterilizer the air-cock at the bottom was opened till all air was expelled. This took 5 minutes. The air-cock was then closed, and the pressure allowed to rise to 20 pounds, when the mercury stood at 122° C. The time occupied in the whole process of raising the temperature to 122° C. was 8½ minutes. In the last experiment with the air left in it took 30 minutes to reach 104° F.

Experiment III.—This was to test the efficiency of the ejector in getting rid of the air. With the steam at 20½ pounds the ejector was turned on and left till the pressure had sunk to below 20 pounds. This was repeated six times. It took 6 minutes. The steam was then let into the sterilizing-chamber and the pressure maintained at 20 pounds. At the end of 12 minutes from the beginning of the ejection the mercury stood at 10° C. At the end of 20 minutes it had reached only 104⅓° C. The air was let out and was found to be about 2½ liters.

The temperature quickly ran up as in the previous experiments as soon as the air was all expelled.

I used the following method for determining when the air was all out: To the air-cock I attached a tube and carried its end beneath water. As long as there was much air being expelled it would bubble up briskly. As the air became nearly exhausted the bubbles would shrink to a small size on leaving the tube, being mostly steam. When the air was practically out the bubbles became almost invisible, and a water-hammer was established, making a noise like the explosion of a bunch of firecrackers. This seems to me an exceedingly simple, striking, and accurate method of determining when the air is all out of a pressure-sterilizer.

My experiments with the pressure-sterilizer show that a pressure of 20 pounds above the 15 pounds of the atmosphere gives no assurance of a high temperature at the bottom of the sterilizer unless the air is expelled. The method of exhausting the air by an ejector before the steam is let in is doubly feeble, for, in the first place, it will take out only a portion of the air, and in the second place, as soon as a partial vacuum is produced more air will be sucked in through the leaks which always exist in such an apparatus. The methods which get rid of the air by progressive dilution are very slow. The quickest method is also the simplest—merely to let the steam enter at the very top, the air flow out at the very bottom and bubble up through water. As soon as a sharp water-hammer, with very minute bubbles, is established, the air is out for all practical purposes, and the temperature throughout the interior of the sterilizer corresponds to that of saturated steam at the pressure indicated by the gage.

THE MORE UNUSUAL FORMS OF PUERPERAL HEMORRHAGE.

By S. MARX, M.D.,
of New York;
Attending-Surgeon to the New York City Maternity.

The absolute safeguard against hemorrhage from an atonic uterus post-partum is perfect retraction and contraction of the muscular fibers of that organ. This condition can be brought about in nearly all cases by ordinary care and skill on the part of the accoucheur, and, in fact, is beautifully accomplished by unaided effort on the part of Nature in the largest number of instances. These ordinary cases of post-partum hemorrhage are entirely foreign to this paper; the attempt to be made is a recital of puerperal hemorrhages of rare origin, and in all of the cases reported the condition was a desperate one.

The history of the first case is certainly a very unique one, and was seen with the medical attendant, Dr. L. A young woman, a divorced one, found herself pregnant, and outside of her melancholic state because of her social position, enjoyed good health until five-months' pregnant. Without cause she then began to have labor pains, and was delivered in a natural manner of a fetus surrounded by an intact fruit-sac. The uterus contracted well, and the convalescence was apparently normal except for a rather profuse and prolonged bloody lochia. At the end of one week, much to the surprise of her physician and to her own chagrin, labor pains began again, and in a few hours a second fetus was expelled, and with it a macerated placenta. Her convalescence was apparently normal, except for some slight intermittent pain and a slight hemorrhage. Suddenly, *five weeks* after the birth of the second fetus, and accompanied by a very profuse hemorrhage which caused a marked anemia, *a third intact fetal sac* filled with liquor amnii was expelled. No trace of a fetus could be found. After a stormy convalescence the patient fully recovered her health. Before leaving her, a direct and thorough manual exploration was undertaken, with the idea in view of finding still another but possibly hidden fetus.

This case need not be commented upon, except that it is well to remember that pain and hemorrhage are *always* inconsistent with a normal puerperium, and when these two conditions are present a direct manual examination is always in order.

In the next case, the puerperal hemorrhage was a direct result of a traumatic insult offered an overdistended bladder eighteen hours after labor, the source of the hemorrhage being partially vesical and partially uterine.

The patient, a primipara, was seen in consultation after a normal labor. The placenta showed no disposition to expel itself, and after six hours the Credé manipulation was carried out at short intervals for twelve hours. There was constant but mild leakage of blood from the vulva. My assistance was asked for, and on my arrival a rather peculiar condition of affairs was found. The hand of the doctor was placed over a large boggy mass, the fundus of which was on a level with the umbilicus. This was the organ upon which the Credé method of expulsion had been practised, and which was soon proven to be the overdistended bladder. To the left of this tumor, its fundus reaching to the level of the ensiform cartilage, was the long-drawn-out uterus containing the placenta, which lay unaborted in its cavity. The bladder was quickly emptied of a large amount of deeply stained, bloody urine, and the placenta delivered with no trouble whatsoever. The uterus contracted well, and instantly took its position as soon as the bladder was emptied.

The lesson to be taught by this case is both instructive and valuable. A full bladder in the parturient woman can and is likely to cause as great a dystocia as a real pelvic contraction, and to my

mind it is as essential to prove the bladder empty by the catheter and not by questioning the patient or nurse, as it is essential to render the examining finger rigidly and scientifically aseptic. A woman may pass water regularly at short intervals, and yet carry a veritable reservoir in her abdomen. Note the cases of ischurie paradoxa, the incontinence of retention so characteristic of incarceration of a retroflexed, gravid uterus. To make this point even more emphatic, let me illustrate by the history of the following case actually seen by me in consultation:

A neurotic second multipara; had always menstruated regularly. Last menstruation in October; skipped her November period, and again had her flow, but yet very slight in December and January. There were present all the symptoms of pregnancy, and the patient considered herself in that condition. During the previous seven weeks she noted a rapid development of an abdominal tumor. She had had irregular temperature and rapid pulse, but otherwise had felt well. She, as well as her physician and the nurse, stated that she had been passing a large amount of urine regularly. On examining her abdomen, I saw that she had the appearance of being about seven-months' pregnant. The abdomen was filled by a tense, elastic, fluctuating mass, situated directly in the median line. No intermittent contractions so characteristic of pregnancy could be elicited. There were no fetal heart-sounds nor small parts to be noted. On vaginal examination it was difficult to introduce even one finger because of the enormous edema of the rectovaginal septum, the collateral edema evidently being due to the pressure from the tumor. The enlarged pregnant uterus was found pressed back in the hollow of the sacrum. Upon following out my invariable rule, never to fail to use the catheter, much to my astonishment the tumor slowly but surely disappeared in the form of *seven and one-half quarts* of urine. The previous diagnosis by the family doctor had been a malignant intra-abdominal growth.

Late secondary hemorrhage on the tenth day of the puerperium is a rare complication, yet in the following case an overdistended bladder, which evidently caused this bleeding, rendered the patient so exsanguinated that her life was despaired of for a number of hours.

The patient, a young primipara, was seen by me with Dr. Breitenfels of this city, after she had been in labor for a number of hours. Upon examining her I found a transverse impaction of the fetal head at the brim. Axis-traction delivery followed, and her convalescence was so uneventful that the doctor stopped his visits on the seventh day at the suggestion of the woman because she felt so well. On the tenth day so frightful a hemorrhage occurred as to give the classical picture of an acute, intense anemia. At the time of my seeing the patient with the doctor we found the fundus pulled up to a point two-fingers' breadth below the umbilicus, and drawn well to the right side of the abdomen. The bladder was found overdistended with urine, the result of a retention of thirty-six-hours' duration. This was the only abnormal condition found, and evidently caused this sudden uterine relaxation and the consequent terrific hemorrhage. When the catheter was passed the uterus was found to be small and fairly contracted, and after thoroughly washing it out the organ was packed with gauze, and measures taken to combat the desperate state of the patient. The convalescence was a very tedious one, but the woman finally recovered.

Partial retention of urine in the recently confined woman I have so very often met that certain physical signs are very characteristic. When one palpates the abdomen the uterus is always found dislocated to one side or other of the abdomen, usually the left. This dislocation is so closely associated in my experience with a partially distended bladder that notwithstanding the statements of all parties concerned, I invariably allow the use of the catheter, with the result that a considerable amount of residual urine is discovered, and upon its removal the fundus promptly moves into place behind the symphysis. On several occasions I have found the whole uterus retrodisplaced from an overdistended bladder. This position favors retention of lochia; with decomposition the condition called "lochia metra" is found with its concomitant symptoms of a true sapremia. The treatment is self-evident, being both prophylactic and curative.

The next case to report is one of very severe bleeding, occurring seventeen days after labor. This case has been reported in full in *The American Gynecological and Obstetrical Journal*, under the title of "Inversion of the Puerperal Uterus." The history is given direct from this report with the associated comments:

Attending physicians, Drs. J. McGillicuddy and Smith. A second multipara was delivered rapidly. The case ran an uneventful course except for a marked subinvolution of the uterus and a prolonged bloody lochia. The placenta and membranes had been expelled entire, and there had been no fever nor pulse-rise nor fetid lochia. When dismissed the woman still had a large uterus, the fundus of which rose well out of the pelvis. Seventeen days after labor, while at stool, the patient was seized with intense pain in the abdomen while attempting to discharge some very hard fecal masses. The passage of feces gave her severe pain, and she was compelled to use considerable expulsive effort. The pain was agonizing, of an expulsive character, situated in the lower abdomen. A very severe hemorrhage occurred, and this, with the increasing bearing-down pain, caused her to faint. She was put to bed, and her physician hurriedly summoned. The symptoms were those of a very severe anemia—

alarming pallor, and a very rapid pulse. Large clots of blood were continually expelled from the vagina.

Upon making an examination, I found the abdomen very tense, but there was a cupping of the fundus about two-fingers' breadth above the symphysis. A number of clots were found in the vagina, and high up in the canal there was a friable, soft mass, about the size of a closed fist, protruding through the os, and tightly embraced by the cervix. At first this mass appeared to be the fundus, partially inverted, but on more careful examination it was thought that there could be traced upward from the mass a very broad pedicle. Further and closer examination could not be made on account of the bad general condition of the patient, who now had a running, almost imperceptible pulse. Examination and operative treatment was postponed twelve hours with the hope that the patient might react. The entire vagina was tightly tamponed with gauze, and repeated enemata of salt water and strychnin were ordered. At the next examination it was found that the patient had reacted nicely. There was no further hemorrhage; the pulse was 110, and very good. Ether narcosis; tampon removed. The vaginal tumor proved to be an organized fibrous placental polyp, about the size of a goose-egg, attached by a long and broad pedicle to the right lateral uterine wall and fundus. In delivering itself it had partially inverted the fundus and corresponding lateral wall of the uterus. Its attachments were readily peeled off with the fingers, the growth delivered, and the uterus and vagina tamponed with gauze. The patient died some weeks after the operation, but the cause of death is unknown.

My remarks at the time the report of this case was made were pertinent, and I think timely, and will bear repetition now: "The cause of the tumor's formation was probably either from a placental rest, or, what is more probable, from a "placenta succenturiata." The only symptoms which should have made the physician suspicious were the subinvoluted uterus and the prolonged bloody lochia. Either one or the other of these symptoms is sufficient to warrant the medical man in insisting upon a physical exploration of the uterus, when the presence of secundines would have been discovered and removed. As a rule, when placental or membrane tissue remains behind, no trouble need be anticipated, providing we are reasonably sure of our asepsis. I cannot agree with those who will insist upon entering every peurperal uterus when there is a suspicion that a small piece of placenta or membrane remains behind, for it is known that in a majority of cases these are expelled spontaneously or can be washed away or otherwise artificially removed when the occasion demanding their removal arises. The indications for their removal need not be a fetid lochia nor a temperature nor a rapid pulse, which symptom-complex is usually associated with a sapremia, but a severe degree of after-pains, persistent especially when ergot is not given, *in a primipara*, after-pains being most suspicious. A subinvoluted uterus and a persistent bloody lochia is quite enough evidence to the careful observer to demand an exploration."

In the following we had to deal with an enormous vulvovaginal hematoma, one of colossal dimensions, the largest ever coming under my observation.

The patient was a young primipara, a typical scorbutic, but only so since becoming pregnant. Her body was covered with old and new ecchymotic areas, and the gums were swollen, reddened, and bleeding. She had a perfectly normal labor, and was delivered readily by means of the low forceps. There was no unusual bleeding, and it was hoped that no complication would occur. She was carefully watched by the house-surgeon, who noted a very gradual growing anemia. The patient complained of decided pressure symptoms in the lower vaginal tract. Tentative treatment being of no avail, I was notified.

The examination revealed the right labium majus, the external genitals, gluteal and perineal region to be the site of an enormous blue-red tumor the size of a fetal head, and evidently on the point of rupturing. This hemorrhagic condition extended around the rectum up the right vaginal wall into the corresponding broad ligament. There was no uterine rupture. The patient was in a condition of profound collapse, and was alarmingly white. Nevertheless, under a careful A. C. E. narcosis the vulva was laid completely open, and a large amount of clotted blood removed. The cavity exposed, which was an enormous one, was thoroughly irrigated. The size of the cavity can be best judged of when forty-two yards of two-inch gauze was required to pack it. While on the table the patient received one pint of salt-solution under each breast, which materially improved the volume of her pulse. During the same night she suddenly developed an acute edema of the lungs, for which 2½ grains of camphor in oil was given every twenty minutes under the skin, and this with inhalation of oxygen and cupping caused this very grave condition to disappear. The cause of this sudden pulmonary edema was evidently due to diffuse pulmonary emboli, because in forty-eight hours the patient developed disseminated areas of consolidation throughout both lungs, the so-called embolic pneumonia. She made a clean though slow convalescence, only to die some months after from an acute general tuberculosis.

The occurrence of a scorbutic condition during pregnancy was the only one of the numerous interesting features of this case to be discussed, and this because of its rarity. It seems hardly possible to account for its direct occurrence, since it is known that the coagulating properties of the blood are materially increased during pregnancy, the so-called

"hyperinosis of pregnancy." For this reason the impoverishment of the blood is certainly overbalanced by this hyperinotic condition, and the increased thickness of the whole vascular system due to its physiologic hypertrophy. An interesting question arising is the following: Are we justified in advising the induction of premature labor in patients of a hemorrhagic tendency? For this indication, pure and simple, I think not, for the only complication to be feared is hemorrhage, and this, uterine, and post-partum. This certainly is as readily controlled at term as at a much earlier period, since in the tampon we have a method for checking uterine hemorrhage that rarely fails us. But in certain of these cases I can readily see that the induction of premature labor is not only justifiable but sincerely to be wished for—cases in which there is associated a profound condition of anemia. This I have met with once, but my wish to induce labor was overruled by the patient and a prominent gynecologist whom the patient saw unknown to me. Yet to-day, in looking back at the case, I am happy that the patient proved disloyal to me and followed the wish and advice of the other practitioner, for four weeks later she died suddenly, probably from a cardiac thrombosis. Had I operated upon her under narcosis what would have been the result of the operation? I think death, for I believe it is Olshausen who says: "Do what you will medically or surgically, these malignant blood cases die whether delivered or not."

The next case to be reported belongs, I think, to the category of the cases just discussed, although we could elicit no history of hemophilia either before or during pregnancy, but the patient died from a general vulvo-vagino-uterine hemorrhage which was not to be checked by any means short of tying the uterine arteries, and this even was problematic.

An eight multipara, seen with Drs. L. L. Bradshaw and Palmer. Because of a partial placenta previa the attending physicians performed a careful manual dilatation of the uterus and succeeded in a few minutes. Then the trouble began, for the patient began to bleed in a furious fashion and in a short time was profoundly anemic. It was impossible to determine where the bleeding came from, for it did seem that all parts of that woman's genital tract leaked blood. The uterus was firmly packed with gauze to the fullest degree; then the cervix bled profusely. It was completely closed over the tampon, the whole canal being occluded. The vagina now bled furiously. Firm tamponade, pressure, hot and cold water, styptics, iron, alum, etc., did no good. Large circular sutures were now passed, including all the parts of the vagina. This stopped the bleeding which we hoped to control, but the needle-punctures bled worse than the original points. Over these again the firm tampon was used, which we found evidently checked the hemorrhage. But the bleeding ceased because the patient had no more blood to lose; she was deeply and profoundly collapsed. Intravenous transfusion was now practised, but the increased vascular pressure brought about by the infusion started the vagina to bleeding again and in a short time the patient was dead. The attempt to tie the uterine arteries was thought of, but the fear of additional shock to the patient stayed our hands from attempting it. Pressure on the aorta was not used since its pulsation could hardly be felt, and further, because the hemorrhage was as much venous as arterial. Everything that mortal being could do was done; and yet we felt that the patient was slowly but surely slipping away from us. I shall never forget the impression made on my mind by this case, for it was the most desperate and sorrowful one I hope ever to meet. This patient was placed in a modified Trendelenburg position (inverted chair) and I think this was a mistake. True, it relieved temporarily the acute anemia of the brain, but while we thought we had the hemorrhage controlled we did so because we did not see the blood. Because of the position none appeared to escape from the vulva; it simply followed the law of gravity and gravitated into the cul-de-sac until it was too full to hold any more and then it percolated through the gauze and escaped from the vagina.

The next and last case to be reported in this paper is one of fatal secondary hemorrhage from a lacerated cervix.

Multipara: three children. Family and personal history, present and past, good. History of previous pregnancies, labors, and puerperia normal. Went into labor at the end of pregnancy. Examination at beginning of labor revealed a deeply lacerated cervix with a breech presenting. Child born practically spontaneously, the whole labor lasting ten hours. After the birth of the child there was considerable hemorrhage from the uterus, for which the whole uterovaginal tract was tamponed with sterilized gauze. There was noted at the time a laceration of the cervix, but the source of hemorrhage was thought to be due to an atonic uterus. The packing perfectly controlled the bleeding. The patient was very much weakened but rallied nicely and began to improve. As is our custom at the hospital, the gauze was removed on the third day. At once, following this, came a very profuse arterial hemorrhage. The whole canal was instantly repacked, but in spite of all measures the patient was dead in one hour from the time the packing was removed. This alone would show how profuse was the bleeding, but the autopsy, performed the following day, threw some light and much interesting information on the case. It showed the futility and danger of packing in cases of cervical hemorrhage. The right side of the cervix was torn past the internal os and into the broad ligament. The whole cellular tissue was infiltrated and suffused by the enormous concealed hemorrhage, stripping up

the cellular tissue, retroperitoneally, right up to the right kidney region, and touching the lower border of that organ. There is no doubt in my mind that the firm vaginal packing simply concealed the hemorrhage, which had been going on quietly during the three days following the labor. Having no external escape the blood was dammed back into the retroperitoneal tissue, and thus was diffused where the autopsy revealed it. The liberation of the gauze simply started up the severe external, visible hemorrhage, and this, combined with the concealed hemorrhage, was sufficient to cause so rapid a lethal result.

The lessons taught by this case are certainly pointed ones, showing the harmfulness and futility of uterovaginal tamponade in cases other than atony of the uterus. In cases of atony, there is no firmer and stancher believer in the regularly applied uterine tamponade than I; I have never noted a failure from its use, and always use this means in every case of uterine hemorrhage when one hot intra-uterine douche fails, and for this purpose always have constantly in my obstetric satchel ten yards of sterilized gauze five inches wide, tightly packed in a very small tube. Otherwise is it in cases of hemorrhage from the cervix. Here and here only do I find the legitimate indication for the use of suture and needle. I do not understand the utility of a primary cervical operation simply because of a cervical tear deep or otherwise so long as there be no hemorrhage. My reasons have been frequently stated, but in short they are these: If the accoucheur has been surgically clean all tears will as a rule heal without trouble. If sutures are applied, and asepsis has not been rigid, sepsis is likely to follow, and either the stitches must be removed, or, if not, union will not take place. Therefore, only in the presence of cervical hemorrhage is the primary operation countenanced.

A RESUME OF MY EXPERIENCE IN INTERNAL ANTERIOR URETHROTOMY.

By G. FRANK LYDSTON, M.D.,
OF CHICAGO, ILL.;
PROFESSOR OF SURGICAL DISEASES OF THE GENITO-URINARY ORGANS AND SYPHILOLOGY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF ILLINOIS (CHICAGO COLLEGE OF PHYSICIANS AND SURGEONS).

During my term of service as resident surgeon in the New York Charity Hospital many years ago, I had the then unappreciated good fortune to serve under Dr. Fessenden N. Otis, whose original work in genito-urinary surgery has put the practice of American surgeons in that branch of surgical science far in advance of that of any other country in the world. My hospital opportunities for the study of genito-urinary disease, particularly in the direction of operative surgery upon the urethra, were excellent, but being prejudiced not only by the established traditions of the medical profession, but also by the opinions and teachings of my lamented friend, the late Henry B. Sands, who, as is well known, was opposed to Otis and his methods, I did not accept Otis' views until some time after entering private practice. Increasing experience then demonstated to me not only the inefficacy of all the time-honored methods of treatment of chronic urethral disease, but the soundness of Otis' views and the scientific accuracy of his technic, and I began practising the Otis method. Further and extensive experience has demonstrated to me its value and has convinced me that Otis' views as originally presented were in the main sound and that his ideas upon the relation of stricture, particularly of large caliber, to chronic inflammation of the urethral mucous membrane and to various reflex disturbances in different portions of the genito-urinary tract, or even remote nervous disturbances, were correct.

My internal urethrotomies of all degrees of importance have numbered something over 1500, and it is with a firm conviction of the value of the operation, born of this moderately extensive experience, that I present the conclusions embraced in this short paper.

The Value of the Operation of Internal Urethrotomy in Chronic Urethral Discharges.—There are several conditions of the urethral mucous membrane and sub-lying tissues incidental to localized chronic inflammation which, in my opinion, cannot be successfully treated except by the radical operation of dilating urethrotomy. I will state in this connection that I do not advocate urethrotomy in any case save those in which a thorough trial has proved the inefficacy of such methods of treatment as gradual dilatation, or local applications of various kinds by means of the endoscope and deep urethral syringe, or in cases in which a distinct coarctation of the canal is present of a character which experience has demonstrated to be incurable by any other method of treatment than division with the urethrotome.

There is a general impression to the effect that urethrotomy is never indicated save in cases of extreme urethral contraction. In cases of this kind my experience has shown that when it is possible to do so, it is best to begin treatment by dilatation and to continue it to the end, providing the coarctations show a disposition to yield. Urethrotomy is attended by best results when the necessary incisions are shallow. In cases in which there is extensive contraction of the urethra, however, the wound necessitated by thorough division of the coarctation is necessarily extensive. Subsequent cicatricial contraction is proportionately great; the interference with the circulation and possibly interference with

the functional capacity of the organ involved is also proportionately great. There are many instances in which endoscopic applications, deep injections, and dilatation by means of sounds or other contrivances absolutely fail to relieve chronic urethral discharges, and careful examination shows that while the entire circumference of the urethra is not involved in stricture, there exists at one or more points in the pendulous portion of the canal thickened, infiltrated, and hyperplastic areas that limit the distensibility and impair the elasticity of that portion of the canal.

These parts are sensitive to the contact of the passing urine and instruments, and induce at the point of the canal in which they are situated more or less spasmodic obstruction, with consequent friction. The involved part of the canal is never at rest, and in a large proportion of cases, I know of no means of putting it at rest and bringing about resolution and cure other than division of the stricture and inelastic area. The alterative effect, if you please, or better perhaps, the local depletion or improvement in the process of healing incidental to the incision has much to do with the cure of the localized inflammation, and with the cure of the localized inflammation the discharge usually ceases. Strictures of large caliber, involving the entire circumference of the canal, are in my opinion rarely cured, even though the symptoms dependent upon them apparently disappear, by any other method of treatment than internal urethrotomy. I am well aware that something of a reaction is in progress against the views of Otis with reference to this particular type of stricture. This reaction is not to be wondered at, considering the erroneous teachings of some of our text-book authors who dwell upon this subject. The non-surgical surgeons, who, while enacting the more fitting rôle of dermatologists, at the same time affect genito-urinary surgery have imparted some erroneous ideas to the profession on this subject. I have in mind two recent text-books, in one of which the assertion is made that any urethra that will admit a No. 26, French, sound cannot possibly be open to impeachment on the ground of stricture, much less should it be operated upon, a caliber of 26 being amply sufficient. In the other it is stated that the extreme capacity of the urethra is 30 or possibly 31, French. That these estimates are inaccurate and are not the result of personal observation in the performance of urethrotomy I am firmly convinced. I firmly believe that in a hundred individuals, taken at random—providing they have had no urethral disease whatever—the caliber of the urethra will average 35, French. The range of caliber between this average and 26, or even 30, is considerable, and anywhere between these limits a stricture of large caliber is perfectly capable of producing urethral discharge and other symptoms characteristic of chronic urethral inflammation, which will not yield until the diseased area is divided by the urethrotome. I have myself operated in cases in which the caliber of the stricture was 35 and upwards, and in two cases I restored the urethra to a size that permanently admitted a 45 bulb.

Prognosis of the Operation as Regards Cure.—I know of no disease demanding surgical methods of relief which has been judged so unfairly as stricture of the urethra in its relations to chronic urethral discharges. It is apparently demanded by non-surgical genito-urinary surgeons that internal urethrotomy should be successful in every case of chronic urethral discharge in order that its value may be proven. I do not know of any other disease susceptible of surgical interference in which so arbitrary and unreasonable a demand is made. A few uncured gleets out of a large number of cases in which urethrotomy is practised for their cure is apparently sufficient to excite a vociferous howl on the part of the anti-urethrotomists. It is not claimed by intelligent urethrotomists that the operation cures in every instance, nor is proof of such a claim necessary to establish its value. As far as my own experience goes I have found that in quite a large proportion of cases of stricture of large caliber, with associated and dependent gleet, a cure is accomplished by urethrotomy. I have found, furthermore, that cure without urethrotomy, while perhaps not impossible in all cases, appears to be impracticable in very many of them. In cases in which strictures of large caliber exist there is danger of deep seated urinary infection in portions of the canal more important and vital than that primarily affected by the stricture. This danger may be removed in many cases by urethrotomy, even though the gleet dependent upon the stricture is not cured. Chronic inflammation of the urethra involves infection and chronic inflammation of the urethral glands and follicles; they are not always accessible, and chronic inflammation, with a discharge dependent upon urethral catarrh, may exist indefinitely even after the original cause—stricture of greater or less caliber—has been removed. Recurrent attacks of inflammation of the prostate and bladder, with marked perturbation of the function of micturition, are often dependent upon strictures of large caliber in which there is little or no apparent obstruction although evident continuous infection exists. This condition of affairs may exist even though there may be no external discharge from the urethra. Such conditions are, however, frequently relieved with astonishing rapidity by the operation of urethrotomy. Frequent

diurnal and nocturnal micturition of a purely reflex character, incidental to strictures of large caliber, is quite frequent. Many such patients coming under my observation have been treated for a prolonged period under the supposition that the disturbance of the function of micturition depended upon inflammation of the prostate and bladder, despite the fact that the urine showed no evidences of inflammation of the mucous membrane of the genito-urinary tract, and no urethral discharge existed. In many such cases the relief afforded by an internal urethrotomy has been surprisingly prompt and permanent. Many cases have come under my observation in which recurrent attacks of epididymitis dependent upon strictures of large caliber in the pendulous portion of the urethra occurred from time to time, and proved absolutely resistant to treatment until internal urethrotomy had been performed. In such cases there is obstruction of the pendulous urethra with coincidental imperfect drainage and constant infection that can only be relieved by operation.

Prognosis as Regards Untoward Results.—A great deal has been said by the opponents of internal urethrotomy regarding the evil results supposed to accrue from the operation. With respect to this point, it is a difficult matter to estimate the true status of the operation. The operation of internal urethrotomy performed by one surgeon may be as different from the same operation performed by another as an operation of a totally different character would be. I know of no field in surgery that requires more careful discrimination of cases, nor riper judgment born of experience as to indications for and limitations of the operation than internal urethrotomy. My experience has demonstrated to my own satisfaction that this operation is rarely followed by untoward results when properly performed. The proportion of disagreeable results is so small as to have very little weight in the balance with the beneficial effects of the procedure. Dribbling of urine as a consequence of interference with the continuous wave of contraction of the accelerator urinæ muscle characterizing the finale of micturition is, it must be confessed, an occasional result of the urethrotomy cicatrix. This is sometimes productive of considerable inconvenience, rarely more so, however, than is the stricture for which the operation was practised.

Continuance of urethral discharge is by no means unusual even after a skilful operation for stricture. It must be remembered that this continuance of discharge may be dependent upon the fact that the operation of internal urethrotomy has been so long deferred that secondary conditions of an incurable character have developed, which continue after the removal of the original source of the difficulty. Again, the urethrotomy might not have been properly performed, and one or more bands may still remain in the urethra and perpetuate a chronic inflammation behind them, with coincident gleety discharge.

Pseudo-impotency, although rare, is met with sufficiently often after internal urethrotomy to demand consideration. When it does occur the patient usually believes that some nerve, as he expresses it, has been divided, with resultant loss of the function of the organ. Obviously a proper urethrotomy incision can in no possible manner by interference with the nerve-supply of the organ produce such a result. That extensive cicatricial contraction, adhesion, and inflammatory deposit at the site of the urethrotomy and about it may produce interference with the circulation to such an extent as to impair its erectile function, is admitted. This, however, is rare, and if all obstructions and sources of irritation have been removed resolution usually occurs in time. Impotency following urethrotomy under ordinary circumstances is of the pseudo type and due to psychic perturbation, being, therefore, susceptible only to remedies producing a psychic counter impression.

Permanent chordee following internal urethrotomy is occasionally met with. It is due to extensive cicatricial contraction following more or less diffuse inflammation in the vicinity of the urethrotomy wound. The mechanical condition upon which it depends is a glueing together, so to speak, of the planes of areolar tissue underlying the mucous membrane upon the roof of the urethra, because of which they do not glide upon one another as they should do during the variations of the size of the organ, incidental to a fluctuating blood-supply in the erection. I have not seen more than two or three cases of permanent curvature of the penis as a result of internal urethrotomy, and even in these apparently permanent cases I have been somewhat in doubt as to the final outcome, having lost track of them after a variable length of time. My experience goes to show that the curvature yields more rapidly in cases in which the patient indulges in sexual intercourse within a reasonable period after the performance of the operation. The active performance of the erectile function of the urethra seems to break up adhesions and promote a return to the normal circulation of the parts. As already intimated, a few permanently disagreeable results should not be permitted to be weighed in the balance with the multitudinous cases in which the operation is followed by successful results without disagreeable sequelæ or complications.

Immediate Results of the Operation.—The condition most likely to give the surgeon annoyance is, in my experience, urethral hemorrhage. Occasionally this is quite severe, rarely dangerous. In cases of hemophilia the danger would, of course, be especially marked, but such cases are very rare. I have found that careful, firm bandaging of the penis from the meatus to the root of the organ is usually effective in checking hemorrhage. By the time the patient is called upon to urinate permanent hemostasis has usually occurred. In cases of annoying hemorrhage following internal urethrotomy I have found emulsion of turpentine, ten minims to the dram, administered every two or three hours, to act moderately well. Turpentine is much more efficacious and reliable than ergot and its congeners. This much may be said with reference to the question of hemorrhage, that there is no danger of serious hemorrhage when once a firm bandage has been properly applied to the penis. Severe hemorrrhage occasionally occurs after an internal urethrotomy at a time when the operation-wound might naturally be supposed to be firmly healed. Thus, I have met with one case in which severe hemorrhage came on two weeks after the operation, a week having elapsed since there was even oozing of blood from the meatus. The hemorrhage came on following a prolonged and violent erection. Experience goes to show that, as might be expected, the greater the sexual repose of the patient the less the liability to hemorrhage.

Urinary fever, so-called, has been of late years the rarest of occurrences in my urethral surgical work. I attribute this to as nearly perfect asepsis as is compatible with the nature and function of the urethra, and to the asepsis of the urine maintained by the administration of oil of eucalyptus internally. Even a slight chill is a very rare phenomenon in my urethral cases at the present time. Other remedies are efficacious, none so much so, however, as the oil of eucalyptus. In a general way, I am prepared to state that the danger of urethral fever is directly proportionate to the frequency and roughness with which the urethra is tampered with by instrumentation after the operation. In by far the larger proportion of cases the introduction of sounds following the operation is begun too soon. The prevalent notion seems to be that unless the urethra is speedily and frequently dilated after the operation its possible benefits will be lost. This, however, is a fallacy. I presume that in the majority of cases it is perfectly safe to defer sounding after urethrotomy for a week. It is rarely my practice to dilate sooner than the fourth or fifth day, save in the case of the meatus, which should be dilated every second day.

Prognosis as Regards Danger to Life.—It is my pleasure to state that I have thus far experienced no fatal results from the operation of internal urethrotomy. I say this simply as a fact which must be accepted upon its merits. I realize perfectly that fatal results have occurred at the hands of very competent operators, and further, that it is by no means impossible that I may at any moment have a like experience. I simply state that such a result has not as yet occurred in my experience. Proper aseptic and antiseptic precautions at the time of the operation, with careful attention to the urine, involving particularly the internal administration of remedies that have a special antiseptic effect upon that fluid, constitute the best means of avoiding serious results. That cases occasionally occur in which even this means of prevention will fail to obviate a fatal result is possible. I do not, however, think it probable. Doubtless in many of the fatal cases that have been reported the urethrotomy *per se* cannot be justly held responsible for the fatal result. It should have been properly attributed to disease of the kidneys. Like all other operations upon the genito-urinary tract involving shock, internal urethrotomy in the presence of more or less serious impairment of the kidneys, as a consequence of long-standing obstruction and urethral infection, may give rise reflexly to hyperemia of the kidney, with complete inhibition of the renal functions, which have already been seriously impaired.

Prognosis as to Permanency of Cure.—I believe that internal urethrotomy in by far the larger proportion of cases of penile stricture of the urethra effects a permanent cure. I have examined cases at intervals after operation varying from one to fifteen years in so many instances that I am convinced that my statement is correct. In a very large proportion of cases of apparent recurrence, the lack of permanency is due either to a fresh attack of the infectious inflammation or to the fact that one or more bands of stricture tissue have escaped division during the original operation.

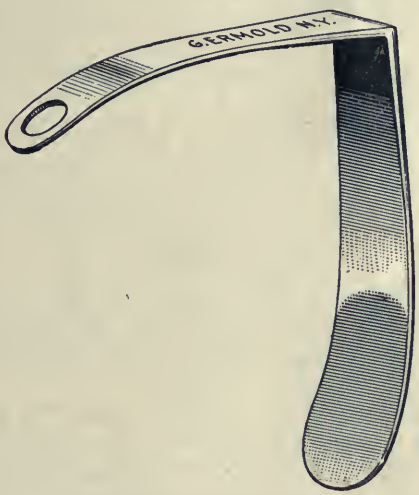
In conclusion, I will state that despite adverse criticism and the endeavor on the part of enthusiasts in endoscopy to cry down the operation of internal urethrotomy, it still remains one of our most valuable surgical procedures, and in a large number of cases of urethral disease is the only practical method of effecting a permanent cure.

Dr. Roux a Member of the French Academy of Sciences.—Dr. Roux, well known for his work on diphtheria serum, and the Assistant Director of the Pasteur Institute of Paris, has recently been elected a member of the Academie Francaise des Sciences of Paris. He succeeds to the chair left vacant some time ago by the death of M. Aimé Girard.

PHARYNGITIS AND TONSILLITIS IN INFANTS.[1]

BY HENRY DWIGHT CHAPIN, M.D.,
OF NEW YORK.

IT has seemed to the writer that many attacks of fever and illness in infants are due to a catarrhal inflammation of the throat, and that such attacks are not infrequently attributed to some other cause. The principal reason for such a possible error lies in the difficulty in getting a satisfactory view of the fauces. This is especially true in very young infants. The tongue is high and the soft palate and pillars of the fauces low down, so that it is extremely difficult to get a clear view of the parts. Unless a satisfactory view is obtained at the first attempt it becomes increasingly difficult, if not impossible, to see clearly at all. The opening is so small that a little mucus produced by the irritation of a second or third examination completely obstructs the view. In addition to this some milk is apt to be regurgitated from



Author's new tongue depressor.

the stomach and then it is absolutely impossible to see the real condition of the mucous membrane.

The writer has had such difficulty at times in satisfactorily examining the throat in young infants that he has devised a tongue depressor for this purpose (see Fig.). Most of the tongue depressors in use are not only too large but do not have the proper slant for the infant's tongue. As a result, the back of the tongue, not being properly held, arches up and obstructs the view of the fauces. The depressor here presented is small enough for the youngest infant's mouth, and is intended to curve over the tongue to the base of the epiglottis. By exercising a little pressure downward and forward the parts will come into clear view. Of course the infant should be properly held and placed before a good light. When everything is in readiness the left hand is used to steady the head while the right hand manipulates the depressor. These details will naturally suggest themselves to the careful physician but are often overlooked, with the result of unduly fretting the infant and failing in the examination.

In infants tonsillitis, as distinct from pharyngitis, is rare. The whole mucous membrane of the pharynx and tonsils is involved in the catarrhal inflammation. The tonsils may be somewhat enlarged and are covered with very fine pin-head points of a whitish exudation. These points can be recognized only when the fauces are well exposed in a good light. In rare instances the uvula is swelled and infiltrated. The secondary forms of pharyngitis seen in most infective diseases will not be here considered. The primary form is apt to be overlooked from the absence of symptoms referable to the throat, and the inability of the infant to call attention to the affected part. The swelling of the lymph-glands of the neck so often noted in diphtheria and scarlatina is not usually present in primary pharyngitis. The two most common predisposing causes of primary throat inflammation in infants are (1) disordered stomach and (2) exposure to cold. The frequent mistakes in the feeding of infants, especially overfeeding, produce an acid fermentation in the stomach. By direct continuity the mucous membrane of the pharynx and mouth may become irritated and inflamed. When the latter happens the temperature keeps up instead of subsiding when the stomach is relieved of its contents by vomiting or by their passage into the bowel. Exposure to cold is likewise a common predisposing cause. Many infants, especially among the poor, are too warmly clad, especially about the neck and chest. As a result the skin is constantly moist. Such infants live and sleep in overheated rooms. In these cases an ordinary exposure to the cold air of draughts will induce throat inflammation.

It will be noticed that the causes here given are mentioned as *predisposing*. Most, if not all, forms of tonsillar and pharyngeal inflammation are due to the presence of microbes. In health and under good hygienic conditions the mucous membrane of the throat may not be unfavorably affected by microbes, but under depressing conditions, particularly when the digestive tract is in an irritated condition, the throats of infants are vulnerable. It is quite possible that many impurities may likewise find their way to the mouth and throat by means of dirty fingers, or objects which are given to infants as toys, and which quickly find their way to the mouth.

The treatment consists in removing the cause, whether it be a deranged stomach, defective action

[1] Read before the Section on Laryngology and Rhinology of the New York Academy of Medicine, January 25, 1899.

of the skin, or faulty hygienic surroundings. The recurrence of attacks of pharyngitis in infants is the most common cause of post-nasal catarrh in children. The repeated irritation induced by these attacks causes hypertrophy of the adenoid tissue at the vault of the pharynx which is the invariable accompaniment of catarrh in the later years of childhood. Frequent irrigation of the nostrils with normal salt solution, or boracic-acid solution, should be employed in all cases in which there is a tendency toward pharyngitis in infants.

To sum up, in order to successfully examine the throat of an infant the parts must be satisfactorily seen at the first examination. By means of the tongue depressor here presented the base of the epiglottis is firmly held at the first attempt and the fauces exposed to view. Pharyngitis and tonsillitis are more common in infants than has been supposed, and are a fruitful cause not only of present discomfort but of post-nasal catarrh in children. Repeated attacks will surely cause enlargement of the adenoid tissue at the vault of the pharynx as well as of the faucial tonsils.

CLINICAL MEMORANDUM.

A CASE OF ŒSTRUS HOMINIS.

By MAXIMILIAN HERZOG, M.D.,
OF CHICAGO, ILL.;
PROFESSOR OF PATHOLOGY IN THE CHICAGO POLYCLINIC.

LARVÆ of the insect order *Diptera* (flies) play quite a prominent rôle as parasites of several of our domesticated animals. On the other hand, it is quite rare, at least among civilized nations, that species of the genus *Œstrus* or *Hypoderma*, which so commonly deposit their eggs for development in the skin of cattle, sheep, and horses, select the human race as the unwilling host for their fertilized ova. A case of this kind is reported in this short communication.

Cobbold,[1] in his extensive monograph on parasites, reports a few œstrus hominis cases, some of which he has seen himself, while the others are collected from literature. Among Cobbold's list of cases we find that of the celebrated African traveler, Livingston, from whose leg a maggot, the larva of an œstrus, had been removed. This specimen is still to be found in the Hunterian Collection in London. Other cases cited by Cobbold were observed in Brazil, and other parts of South America; two cases occurred in the persons of traveling entomologists; one case in a young boy in Texas, etc. Voelkel[2] observed a case in Germany, in a young boy. The larvæ, as Leukart and Bauer thought, were those of *Hypoderma Diana*. Shimoneck[3] saw a case in an infant two weeks old. The child had been born prematurely at seven months, and when about ten days old developed swellings all over the body. These contained, as was soon discovered, the larvæ of *œstrus bovis*.

The case herein reported was observed in Duncan, Indian Territory, by Dr. D. Long, who forwarded to me, with a request for diagnosis the larvæ found, and the following history:

"December 26, 1898, a girl, four years old, had been restless and sick for several weeks with a low fever of an intermittent type, and nervous symptoms. The discharges from the bowels occasionally contained a good deal of mucus and some blood; her appetite, however, as a rule, was good. Within the last week there had developed a tenderness of the abdomen, and a slight enlargement over the right lobe of the liver. Two days ago there appeared on the right side, between the ninth and tenth rib, a small, red spot, which developed into a vesicle or pustule. On opening the later a living parasite was found protruding from the skin. The maggot was carefully removed with a pair of small forceps, and placed in a preserving fluid."

Since I was myself unable to fully indentify the insect larva I referred it to the United States Department of Agriculture, Bureau of Animal Industry, at Washington, whose chief, Dr. D. E. Salmon, obliged me with the following report:

"A careful examination of the specimen shows it to be very closely related to the genus *Hypoderma*. As it is a very young form I hesitate to attempt its specific determination, but it is very similar to the larvæ of *Hypoderma lineata* at this stage of growth."

A request to Dr. Long to furnish some more of the larvæ could not be complied with, since no more were found upon the person of the little patient, who, after the removal of the one, very soon improved and completely recovered from her troubles.

Hypoderma lineata, the species to which the parasite found, as it appears, belongs, is known also under the name of *Œstrus hominis*, or *O. humanus*, or *Dermatobia noxialis;* in common English as the gad- or bot-fly.

SPECIAL ARTICLE.

THE GARRISONING OF OUR TROPICAL POSSESSIONS.

No. 5.

DUTIES OF SANITARY AND ENGINEER OFFICERS.

By SENECA EGBERT, M.D.,
OF PHILADELPHIA;
PROFESSOR OF HYGIENE AND DEAN OF THE MEDICAL FACULTY IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

HAVING indicated in former articles the dangers that beset our troops in Cuba, it is fitting that the means of guarding against these should now be positively and emphatically declared. Some may, perhaps, feel that I have drawn a picture too somber in tone and magnified the perils that are so full of menace, but all who have read Mr. Hill's paper in the January *Forum*, entitled "Colonel Waring on the Sanitation of Havana," must have been impressed by this paragraph:

"If Havana in its present condition were suddenly peopled with men from our Northern and Western States, the results would probably be as follows: The general death-rate would be very much higher than at present; the proportion of deaths from dysentery would decrease somewhat because of our cleanliness and better dietetic habits; the proportion of deaths from typhoid fever would increase considerably; while malaria and yellow fever would claim scores of victims for every one they gain now."

And though it is encouraging and reassuring to learn that, under General Ludlow's administration, the death-rate of Havana for the past month shows a marked decrease, we must all realize that it is still excessively high, that the fatal conditions and causes still prevail, that many of our soldiers are now in Cuba, and that within three months the seasonal changes will almost surely tend to verify the above prediction.

What, then, may be done to protect our men? At this distance we cannot presume to know or to dictate as to the military or administrative exigencies, but we are firmly of the opinion that in so far as possible the troops should be kept out of the large cities, and, especially, that their camps and barracks should not be located therein. Police work will be distasteful to them, and there seems no reason why such duties should not be performed by trustworthy natives. The Spanish soldiers have departed, and that source of irritation to the public peace has been removed. The population accept our presence not only with toleration but with real friendliness. Any disorders, therefore, will likely be not much in excess of what is normal to large cities, and will not be due to popular distrust nor to a general uprising. Any immediate need for our soldiers could promptly be supplied from camps without the city walls; but, above all, they should *not* occupy the forts and barracks so lately vacated by the enemy, for there is every probability that these are so thoroughly impregnated and infected with the seeds of disease that the most careful disinfection and sanitation could not ensure safety to unacclimatized occupants for a long time to come.

In fact, if the statements are true which Colonel Waring had undoubtedly prepared for his report to the Government, every day that a soldier spends in Havana increases his risk of infection, and this particularly as the wet and warm weather approaches. The selection of the camp-sites must be made with care. They should be as elevated as possible, and far removed both from marshes and lowlands, which are the breeding-place of the various malarial organisms, and from all filth-deposits and drainage-outlets of the city.

The soil should be porous and free from rank vegetation. Artificial should supplement natural drainage whenever necessary, and the level of the subsoil water should be lowered as much as possible. Moreover, this soil-water should not be the drainage from higher elevations, nor should barracks be located in or too near ravines, as it is known that malaria is often carried up the latter by the wind. Some shade-trees about the buildings may not be objectionable, but too many will interfere with the free movement of air and access of sunlight necessary for health.

Of course, these camp-sites must be such as may have a plentiful supply of good water, and every precaution must be taken to prevent this from being contaminated at any point from its source until it reaches the camp and its consumers. Though yellow fever is not often transmitted thereby, we must never forget that water is the customary carrier of the germs of typhoid fever and dysentery, and not rarely of malaria, all three of which are only to be less feared in this country than the first mentioned.

Fortunately, Havana has an excellent and abundant water-supply, and so, I believe, have most of the other larger Cuban cities. Camps in their vicinity should not, therefore, be at a loss to secure a sufficiency for every need.

Should it be necessary or be deemed wise to locate even a small garrison within the city limits, the location of its quarters should be made with forethought and judgment. Any existing buildings would better be completely torn down, all accumulations of filth and sewage thoroughly disinfected and removed, and the soil well under-drained. Barracks and other necessary buildings can then be erected and occupied with far less risk than will be had in any preexisting structures.

In the construction of the various buildings necessary for a garrison or camp of occupation, circumstances must govern many things and features. However, much may be learned from the experience that Great Britain has had in her various colonies, and we may adopt some of her lessons without hesitation or question.

She has found that it never pays to overcrowd, that there must be no interference with the free access of sunlight and air, and also that the buildings should be detached from one another, and best of not more than two stories in height. To this I would add that in Cuba it will probably always be well to have them considerably elevated above the ground to allow a free circulation of air beneath them, aiming in this way to promote dryness of both floor and soil, and to thus prevent the development and transmission of malarial diseases. A height of eight or ten feet above the ground will not be too much, and there should always be room enough, at least, to allow of thorough cleaning. All construction work of this kind must be done with thoroughness and with an idea of permanence, for it is in this way only that the best sanitary results can be obtained.

It will be noticed that it is assumed that barracks will be constructed at each camp-site. It is true that the exigencies of the situation may necessitate for a time and at certain places encampment under canvas, but this should be avoided wherever and whenever possible on account of the increased liability to malaria induced by sleeping so near the ground.

Again, as has been stated, no one now knows how long it may be necessary to maintain the garrisons in this island, and that which may seem expensive at first sight may be truly economical in the long run. Any saving of health and life in this or any other way will be repaid tenfold

financially in the reduction of the pension-list of the future. Great Britain has learned much from experience, but in spite of this the sick-rate of her Indian army, exclusive of native troops, for 1896 is by no means encouraging. From a total enrolment of officers and men numbering 70,484, there were 97,738 admissions to hospitals, or a rate of 1387.7 admissions per 1000, while the average number constantly sick per regiment was over 93, and the average sick time for each soldier exceeded one month. Can we expect to do better in Cuba? It will be only by the strictest observance and enforcement of every sanitary rule and precaution, and by increasing vigilance and care. And if we do not do better, who can measure the increase in the payment of pensions that will be demanded from the Government within the next ten years? The cost of the sanitary reformation and rehabilitation of the whole of Cuba will scarcely exceed it.

The construction of the barracks, hospitals, and other necessary buildings need present no very serious problems. As Notter says:[1] "Barracks have been in our (the British) army, and in many armies of Europe still are, a fertile source of illness and loss of service." The buildings should not be over two stories in height, and should not be designed to accommodate more than a single company of men in each. In fact, not more than one-fourth of this number, say twenty-four or twenty-five at the most, should be quartered in any one room, and each man should have ample floor- and cubic-air space. That is from fifty to sixty square feet of the former, and not less than 600 cubic feet of the latter. This means a ceiling height of at least twelve feet. The rooms should be narrow—twenty feet is wide enough—and with plenty of windows. Broad unenclosed verandas on at least one side of the house will furnish shade and give extra space and protection to the men in wet weather.

Nor should ventilation be dependent simply upon that which may be had through doors and windows. Notwithstanding the mild and equable climate of Cuba, there are times when it is quite cold, and when it is desirable to shut out the draughts and winds, and even to warm the incoming air. Special inlet and outlet flues and openings should be provided in every instance. These should not be larger than one square foot in section individually, but there should be at least one square inch for each 50 or 60 cubic feet of space, or from 10 to 12 square inches per man. This is exclusive of the chimney, which, of course, is adapted to the heating apparatus, but which should remove almost as much air per hour as the outlet flues. For heating apparatus, if any be required, it may be necessary to use stoves, but the so-called Galton or patent ventilating grates are preferable, inasmuch as they not only facilitate ventilation but warm the air before it enters the room.

These houses must not be located so near together that one will keep the sunlight from another, or that the free circulation of air will be prevented. Generally they should be built so as to expose the sides rather than ends to the prevalent winds, which, however, should not come from marshy or polluted localities.

[1] "Treatise on Hygiene," p. 918, P. Blakiston, Sons & Co.

Ample wash-rooms should be provided for each house and in connection therewith, and for these there should be a full supply of water that will allow of frequent and generous baths by all the men. To remove this water after use, a proper drainage system must be provided, whether water-closets are used for the latrines or not, in order that the soil under and about the barracks may be kept dry. But such drains should not be the same, nor should they be connected with those which are employed to drain the soil proper and to lower the level of the ground-water. Wherever possible the drainage from the wash-houses, water-closets, kitchens, and sinks should be carried to the leeward of the camp for at least three or four hundred yards, and had best be disposed of by sub-irrigation or intermittent filtration.

Whether the latrines would better be supplied with water- or with earth-closets is a matter of judgment depending upon several circumstances. The latter are often preferable and safer, provided proper supervision and good service in caring for them can be had. This means that the contents must be removed daily, and covered in trenches sufficiently deep with clean, dry, and absorbent earth. The latrines must be located in buildings separate from the barracks, but may be connected therewith by covered and well-ventilated passage-ways. They must always be kept scrupulously clean. For permanent barracks such as described the ordinary latrines of temporary camps are, of course, not to be considered.

Should the term of our military occupation prove a long one, the advisability of increasing the proportion of married men in the garrisons must be considered. Any such increase with the consequent presence of their families will demand the construction of separate quarters for them, the best type of the latter being low, one- or two-storied buildings, having suites of two or three rooms for each family. It goes without saying that the ventilation, water-supply, drainage, etc., of these must be as complete and satisfactory as the same features in the ordinary barracks.

So also with relation to all the other buildings belonging to the camp or site, such as officers' quarters, guard-house, storerooms, quartermasters' and commissary department, etc. In fact, the whole constitutes a community in which the sanitary provisions, apparatus, and regulations should be as complete and as carefully guarded and observed as in the most Utopian of settlements.

Involved in this must be the instruction of every individual not only in the observance of such regulations, but in the reasons for them, and his education in these matters should continue until he is convinced that his safety is absolutely dependent upon them.

The kitchen and mess-halls should not be in connection with any of the barracks or other quarters directly, but should be located conveniently to them. Here, also, thorough cleanliness and good ventilation should be had, and special precautions taken to prevent any infection or deterioration of any article of the food-supply. The best and safest disposal of the garbage will be by burning, and special cremation-apparatus for this purpose should be provided and used.

As in every model community, the hospitals and adjunct buildings must be located at a safe distance from the rest of the camp, and all unnecessary intercourse with the former must be prohibited. This is especially imperative in times of epidemics, for, besides the increased risk of infection, there is always the danger that the knowledge of many cases in camp may produce, on the one hand, reckless agnosticism and carelessness as to sanitary precautions, and, on the other, panic in the minds of the men. Likewise, the same rules of construction are to be observed here as elsewhere, though a larger amount than usual of cubic space per patient should be provided in the wards, inasmuch as Cuba is tropical in climate. Fifteen hundred or 1600 cubic feet per capita is by no means too great an allowance for ordinary circumstances. The wards should be designed to accommodate ordinarily not more than twenty-four men, but the whole hospital system should be capable of considerable expansion in times of emergency. The three essentials—perfect ventilation, plenty of sunlight, and convenience and efficiency of administration—should be kept foremost in mind in the building. Elevation above the ground is even more essential here than in the case of the barracks. Moreover, the arrangement of wards should permit of the total separation of patients having different infectious diseases, and isolated wards or barracks should also be provided for the detention of suspected cases. Another necessity is a complete disinfection-plant for the treatment of clothing and bedding.

The foregoing is an attempt to indicate the requirements of a model garrison-camp in tropical Cuba. Can we say that the establishment of such a camp would ensure the safety of all or most of its occupants, and protect them from the maladies which otherwise seem almost certain to affect them?

Undoubtedly, it would guard them in a large measure, and especially from such infection, as they most probably cannot escape by their own individual foresight and care. But, after all, a man's own safety is a matter even more intimately connected with his observance of the laws of personal hygiene, and is related to his diet, his clothing, his habits and idiosyncrasies and temperament. It is through the control of these that we can best hope to fend off the dangers that threaten so alarmingly, and it is these that we shall, therefore, next consider.

MEDICAL PROGRESS.

Sudden Death after Child-Birth.—Porak and Durante (*Gaz. heb. de Med. et de Chir.*, December 22, 1898) report the sudden death of a woman who was delivered after an apparently normal labor. There was only a slight loss of blood. On the fifth day there was an elevation of temperature of two degrees. The next day it was normal. There were no other symptoms. On the ninth day while taking her breakfast the patient fell from the bed, and was picked up dead. The autopsy revealed the fact of a double uterus (which had been recognized during life), and a single kidney. The cause of death was found to be a large embolus in one of the chief divisions of the pulmonary artery. This embolus had come from the right hypogastric vein, where there was a slight endophlebitis and a little thrombus. In the thrombus there were numerous colonies of the colon bacillus, and it was thought that this germ was responsible for the endophlebitis and the death of the patient. Infections run a different course according to the agent which produces them. That due to the streptococcus is marked by an elevated temperature, while the colon bacillus gives a latent infection, with little or no rise of temperature.

Position and Size of the Adult Stomach.—Rosenfeld (*Centralbl. f. Inner. Med.*, Jan. 7, 1899) asserts that the adult stomach when empty occupies an almost vertical position, and with the exception of its pyloric portion lies wholly to the left of the vertebral column. Its shape is that of a large reversed C. When it fills with food it swings more to the front. When the stomach becomes dilated it may retain this same position, simply lengthening, or it may assume a more horizontal position, still chiefly to the left of the vertebral column, or it may dilate, especially in its pyloric portion, in which case more of it will appear on the right side than in the other forms of dilatation. Blowing the stomach up with CO_2, or with air by means of a stomach-tube, is a most misleading procedure, as the part of the stomach which is evidently distended under such circumstances is the pyloric portion, the major portion of the organ being concealed by the ribs. Percussion and palpation are better means of investigation in certain cases. Far more exact, however, are the results obtained by the introduction of a soft catheter filled with shot. This sinks with certainty to the lowest margin of the stomach, and if the organ be then dilated with air and radiographed, a picture of the shape and position of the stomach is obtained which is absolutely reliable.

Apparatus for Exstrophy of the Female Bladder.—Bailey (*The Clinique*, Jan. 15, 1899) mentions a case of exstrophy of the bladder which caused the patient considerable suffering as well as constant annoyance up to her thirtieth year. An operation at the ninth year had been a complete failure. Many forms of apparatus had been tried and rejected. The urine which constantly flowed from twenty-eight minute openings in the everted bladder was caught in thick underclothing which had to be changed several times a day. Still the patient pursued her occupation as a teacher. The apparatus which Bailey devised, and which proved very successful, consisted of a receptacle made of aluminum and extremely light in weight; it was forged in one piece, and made to fit tightly at the fourchette and inner part of the thighs. It was ground out to permit a space just over the multi-openings of the bladder. The top part was not allowed to touch the body, thus allowing ventilation, a fault, the patient says, which existed in every other form of apparatus that she had ever tried. The bladder itself did not at any point come in contact with the aluminum. This metal withstands the corroding and oxidation of foul urines. From the most dependent part of the receptacle a tube collected the urine in a cheap thin rubber or oiled silk or paper bag which could be thrown away after use, and

outside of this for protection was a larger rubber bag reaching nearly to the knees. The whole device was held in place by rubber tubing about the thighs and waist.

Metrorrhagia of Puberty.—CASTAN (*Centralbl. f. Gyn.*, January 14, 1899) says that in the metrorrhagia of puberty, which occurs from the thirteenth to the sixteenth years, the bleeding continues almost without interruption from one period to the next. The blood is usually bright red and flows away without pain or leucorrhea. Examination shows that the pelvic organs are normal and not tender. The bleeding is the only symptom. The author attributes it to a dyscrasia due to an intoxication, and his treatment is directed to the strengthening of the whole organism by gymnastics, baths, etc., while arsenic and remedies to overcome the constipation are administered internally.

Vaginal Cysts.—GODART (*Centralbl. f. Gyn.*, January 14, 1899) describes two cases of vaginal cyst, one of supposed embyronic origin, which at the age of twenty-one years was found reaching from the right vaginal vault to the sacro-uterine ligaments. The other patient had borne a child eleven months before she applied for treatment, and the cyst as big as a hen's egg, which protruded from the vagina like a prolapse of the cervix was thought to have its origin in a thrombus which had undergone cystic degeneration after the birth of the child.

Effect of Castration upon Women.—PFISTER (*Centralbl. f. Gyn.*, January 14, 1899) has made an extended investigation into the results of castration upon women, examining and questioning 179 patients upon whom a complete operation had been performed for diseases of the tubes and ovaries, or, in one-third of the cases, for myoma or aggravated retroversion of the uterus. The results were in accord in great measure with those of other investigators, but Pfister worked out the subject so carefully that his conclusions are well worth repeating. Menopause followed in 94.8 per cent. of all cases. It did not follow in two cases of uterus unicornis, and the conclusion seems well founded that in these instances there must have been ovarian tissue in some unusual situation which was overlooked at the operation. Irregular hemorrhage followed in twelve cases. Leaving the operations for myoma out of the question castration had a favorable influence upon leucorrhea in eighty per cent. of the patients. In a large part of the patients the desire for intercourse and the sensuous feeling remained. This he explains on the ground that the desire only is due to the distention of the Graafian follicle in the ovary while the sensuous feelings are excited by the body contact. Both of these causes exert reflex action through the lumbar cord, but it is evident that in a married woman, especially in youth, the recollection of past gratification together with the cutaneous sensation may suffice to make the sexual act practically normal for a long period after the removal of both ovaries. This is not usually the case with unmarried women, or those whose vitality has been somewhat reduced by age or long illness. These facts show that the relations of the vagina and external genitals with the uterus and ovaries are not so close as is usually supposed. In the majority of patients castration was followed by an increase in weight. This was not like the portliness which accompanies the natural cessation of the menopause, but was a rounded, more girlish plumpness. In most of the cases the relief of pain and shrinking of the tumors was satisfactory. Hysteria was rarely benefited. Ventral hernia developed in nineteen patients.

THERAPEUTIC NOTES.

Operation for the Radical Cure of Hemorrhoids.—SCHIFF (*Med. Record*, December 31, 1898) advocates the treatment of hemorrhoids in the same manner that one would treat any other pedicled tumor, that is to incise the mucous membrane around the base of each hemorrhoid, to ligate and cut short the vessels, and then to suture over their stump the edges of the mucous membrane. If the masses of hemorrhoids are too large to remove individually, they are removed in four sections, and some mucous membrane must be left between each of the portions cut away, otherwise there is nothing left to suture. In cases in which there is danger of a stricture, it is advisable to suture transversely, so that the suture line shall be parallel to the sphincter. In ordinary cases, the anterior and posterior wounds may be sutured parallel with the bowel while the lateral wounds are sutured across it. The advantages claimed for this method of operation are: (1) The patient is well in from three to five days. (2) There is less pain during convalescence than follows any of the other operations. (3) By the fourth or fifth day the patient is able to attend to his business, which is a desideratum in these cases. (4) The only difference in time in performing this operation and the clamp and cautery operation is the time consumed in suturing. (5) There is less danger of secondary hemorrhage in this operation than in Allingham's or the cautery operation.

Action of Amyl Nitrite.—WINKLER (*Centrabl. f. Inn. Med.*, December 17, 1898) learned from experiments that the inspiration of amyl nitrite in many instances is followed by a lowering of the blood pressure in the arteries, due to their dilatation, and without any insufficiency of the left ventricle. Under such circumstances the effect of the drug upon the circulation may be favorable by reducing the work of the heart. Unfortunately, this stage of its action is usually of short duration, and is soon followed by an increase of pressure in the left auricle, showing insufficiency of the left ventricle. This condition soon results in swelling and stiffness of the lungs, and edema. From these results Winkler draws the conclusion that we must look upon amyl nitrite not merely as an agent for dilating the blood-vessels, but as one which if given in large amounts acts energetically upon the heart, and often in an unfavorable way. Hence the uncertain action of the remedy in angina pectoris. In the beginning of pneumonia the drug must be employed with the greatest caution.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the Medical News will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SATURDAY, MARCH 4, 1899.

KIPLING'S ILLNESS.

For days the English-speaking people of two continents have awaited in almost breathless suspense the issue of the struggle between life and death made by the most popular genius of the end of the century. In the prime of manhood, with all his well-deserved honors falling thick upon him and the promise of a future difficult to fully appeciate, it was sad to think of him stricken down just as he had passed the threshold of his great career. The world has learned to appreciate genius in these days. It is no longer permitted that one should do the great work that is to be honored of posterity in a garret, to express its inspired message amid discouragement and then starve. The thrill of utterest sympathy that has vibrated through Humanity's great heart in two worlds at the prostration of the great young writer whose words have been a revelation to so many is a hopeful sign of the better understanding among men that these latter years are surely bringing with them.

In the midst of it all the silent unfailing forces of Nature have seemed so heartless and cruel. At a given moment it happens that the material with which is bound up the existence of the beautiful spirit whose emanations have stirred men so deeply becomes a favorable culture-ground for a little plant whose whole sphere of existence is bounded by an infinitesimal portion of almost undifferentiated protoplasm. Implantation takes place, and straightway natural forces foster the growth of the microorganism as if it were a favorite child, heartlessly, cruelly, regardless of the fact that that growth is at the expense of material that is informed by one of the brightest spirits to which the world has ever had the privilege of ministering.

Let us hope that the Purpose that runs through all the scheme has ordained the conservation to us poor mortals, for the present at least, of the poetic, truly creative spirit whose subtle magic has cast a spell over us all. We have all admired the magnificent fight he has made for life. As medical men we have been especially touched by the fact that the forces of Nature in him unmarred by wanton misuse have reacted for self-preservation in marvelous ways; that a past of pure clean living has been the basis on which good hopes of recovery could be founded when disease seemed almost inevitably about to triumph. Let us hope that the encouraging reports of Mr. Kipling's condition will be followed by others and still more favorable ones, and that he shall be spared to us and to another generation to which in the fulness of his power his words will be even more an inspiration and an illumination than they have been to us. *Ad multos annos.*

THE JENNER INSTITUTE—A CORRECTION.

Our London contemporary, the *British Medical Journal*, after the charmingly complimentary expression that "the Medical News is beyond question one of the best edited medical journals in the United States," calls our attention to an error of our London correspondent in associating the name of the late Sir William Jenner with the Jenner Institute of Preventive Medicine. We blushingly make the correction after such a compliment, and feel a little bit as if our correspondent's slip might, under the circumstances, be considered a *felix culpa* since it has afforded the opportunity for such flattering words from our distinguished contemporary.

HONOR TO WHOM HONOR IS DUE.

A few weeks ago in chronicling the death of Sir William Jenner, the distinguished English physician,

we copied from our English contemporaries the supposed fact that Sir William had first convinced the English-speaking world of the essential difference between typhoid and typhus fever. After reading Professor Osler's address on "The Problem of Typhoid Fever in the United States," which we published last week, we feel called upon to correct this misstatement. The enviable distinction of having clearly pointed out the differential diagnostic points in these two important diseases belongs to young American physicians whose studies under their great master Louis at Paris had prepared them for clinical work of a high order. This achievement alone should make their names precious to a grateful medical posterity.

Sir William Jenner himself was only too ready to acknowledge how much he owed on the subject to such men as Gerhard, Shattuck, and Bartlett, and to recognize the fact that he was about to attempt the accomplishment among the profession in England of what these men had already done in America. When he was battling for the acceptance of the advance that had already come in American medicine, a committee had been appointed by the New York State Medical Society to still further elucidate the subject of fevers and note any clinical entities apart from those already recognized. The outcome of the investigation of that committee was, as Professor Osler notes, Flint's classical work, "Clinical Reports on Continued Fever."

"There were giants in those days," and their memory must be ever fresh among us. For their painstaking investigations, so successfully conducted amid all the discouragements to exact clinical work at that time will be an inspiration to generations to come, when American genius shall claim her place in the forefront of medical advance as she has in all the other great movements in which we have become seriously interested.

A DIAGNOSTIC TRIFLE.

"TRIFLES make perfection, but perfection is no trifle" was an expression that occurred in Sir Henry Irving's lecture on "Acting," delivered at Harvard some years ago, and had quite a vogue at the time because of its applicability to so many arts. It would seem to be nowhere more true or more apt than in the science of diagnosis.

It is a well-worn theme that errors of diagnosis are oftener due to the missing of some important link in the diagnostic chain because of hurried or negligent examination, in which some seemingly trivial and insignificant detail escapes notice, than to any lack of knowledge. Exact diagnosis is the result of careful, painstaking application of well-known principles in their utmost detail. Every smallest circumstance may be of the greatest value in coming to a correct decision in the matter and it is the capability of catching the significance of trifles that makes the successful diagnostician.

The improvements in diagnosis in our day are not the applications of new principles but the discovery of the significance of hitherto unsuspected, perhaps unnoticed, conditions. Professor Lampadarios of the University of Athens seems to have hit upon one of these diagnostic trifles. It gives promise of much significance. He has noted in a number of cases of incipient phthisis at an early stage, before bacilli in the sputa are of pathognomonic import, that there is sometimes a râle to be heard at the apex of the lung when the patient is reclining which disappears when he assumes the erect posture. He attributes this to the fact that when standing the diaphragm is principally used for respiration and the lower portions of the lungs take more part in the act than the upper portions. Especially is this true in delicate patients whose muscular development is not great and whose general condition has deteriorated. As a consequence of this, while the patient is erect there is not enough movement of the lungs to properly bring out the râles. While lying down, however, there is not the same reason for the preponderating action of the diaphragm, and, moreover, certain accessory muscles of respiration not vigorously employed in the erect posture have better points of support while the patient is lying down.

These cases of suspected incipient tuberculosis are usually ambulatory. When they come to the doctor's notice the patients are ordinarily examined standing. Professor Lampadarios' experience seems to show that it is possible under these circumstances to miss the very early signs of pulmonary tuberculosis. As the success of therapeutics in the disease depends very largely on early diagnosis and every day is of importance in the matter the significance of the announcement becomes apparent. It has always been

recommended to examine patients suffering from pleurisy or heart disease in the recumbent position; it would seem now that patients with incipient phthisis will have to be treated in the same manner.

PHYSICIANS ON A STRIKE.

IN Germany last fall there was presented the unusual spectacle of a "strike" among physicians. That university graduates should resort to a means of maintaining their rights which has hitherto been the weapon of those who labor with their hands, has excited no little criticism. To understand the condition in which the doctors were placed it is necessary to remember that the poorer classes throughout Europe are banded together for medical purposes into lodges. In France it has been estimated that there are 200,000 of these lodges, and the medical journals of that country are just now up in arms because the managers of these lodges have reduced the age at which a child may be admitted to membership from the sixteenth to the fourteenth year. In Germany it has been customary for the physicians of a given locality, or a part of them, to act as lodge doctors, receiving a stipulated fee for each visit made. The usual fee is one mark (25 cents), for a visit, and one-half that sum for an office consultation. The size of the fee was not, however, the cause of the quarrel between the management of the lodges and the physicians. Some of the most progressive lodges have been introducing what is known as Landmann's system. In accordance with this plan, the lodge engages one or more physicians as may be needed, at a stipulated price, and with the agreement on their part that they will not engage in other practice, while the members of the lodge promise in return that they will not consult any other physician either for themselves or for any member of their families. It was against the introduction of this system that the physicians in Barmen and Remscheid struck. In the latter place they lost their case as the management of the lodges held firm and imported seven young physicians to attend to the health of their members. In Barmen the local physicians were more successful, and with the help of a part of the members of the lodges who were loyal to them, they forced the management to abandon the plan for two years. The tendency seems to be toward the formation of larger combinations of lodges under one management, and on the other hand, in Berlin there is a society of lodge physicians whose object is to look after their common interest.

Perhaps no activity in a community is so wastefully carried on as that of looking after the wants of the sick. Many a physician spends more time in getting about from place to place than he does in doing the actual work for which he is called; while patients travel half way across the continent at great expense to consult some man who may or may not be better fitted to advise them than some one much nearer home. The application of the same methods which have made business and manufacturing concerns grow larger and larger, may one day result in the formation of a medical trust. The preliminary problems are being worked out in Germany at the present time.

The same conditions prevail in England to a less extent, and the *British Medical Journal* of December 10th, laments that any physician in Skipton should be willing to look after the health of the members of a "club" at the rate per year per member of only three shillings. Some of the Skipton physicians held the same opinion and gently whispered "four shillings, please," but the managers of the club said "If you do not like three shillings, we shall get some one from out of town," and the local doctors said no more. The *British Medical Journal* counsels "a little more professional union, which will replace such rates as three shillings or four shillings per member per annum, by those of six shillings to eight shillings. It is often a wise step for the local profession to form a dispensary for their poorer patients in opposition to any medical institute organized by the friendly societies." Dispensaries have been used for all sorts of objects, but here is certainly a novel plan—to start a free dispensary in order to compel a charitable organization to pay higher wages.

MAGNIFICENT ENDOWMENT FOR RESEARCH IN INDIA.—A LESSON.

THE English newspapers have recently announced that Jamsetji Tata, a wealthy native Indian, has given £250,000 ($1,250,000) for the establishment of a teaching university and research institute in India. The scheme of studies and investigation provides for a triple division of the subjects to be

worked at. (1) Scientific and technological, (2) medical and sanitary, (3) educational and philosophical. The new institution is to do post-graduate work entirely, and is not supposed to interfere at all with existing universities in India. The medical and sanitary departments, it is expected, will be given special prominence, and it is hoped that the work done will go far toward making the Indian peninsula more inhabitable for its own sake and less of a danger to the outer world because of the contagious diseases it may foment.

The announcement is of special interest to us as Americans because, it is added, the new institution is to be modeled, in its general features, at least, after our own Johns Hopkins University at Baltimore. The compliment is a most flattering one, but not more than is deserved by the University, whose thorough scientific methods, whose advanced but conservative workers, whose adoption of what is best in the most practical modern pedagogic lines, and whose success in teaching and original investigation have added greatly in these last few years to America's reputation both in England and on the Continent.

To Johns Hopkins we say *Macte virtute.* To American institutions which would look abroad for models for their teaching methods and scientific departments we are tempted to repeat an old saw, *si vis examplar circumspice.* Let us hope that the modern prophet in scientific and educational matters will not be without honor save in his own country. We in America are seemingly just entering on an era of unexampled prosperity. Good times will see the foundation of many a scientific institution and the development of others. May we hope that foundations and endowments will be directed to as good a purpose, and the policies of the institutions they conserve be managed with an eye as single to true scientific progress in pedagogy and investigation as has been the case at Johns Hopkins, *ad majorem scientiæ gloriam.*

ECHOES AND NEWS.

The Wrong Tooth.—A medical practitioner in England was sued recently for £25 damages for extracting the wrong tooth. It seems there was a bony growth at the root of an aching molar which was either adherent to or projected beneath the neighboring tooth. When the bothersome tooth was extracted the other came with it. Judgment was for the defendant with costs.

An English Hospital in Rome.—The English colony in Rome has determined to found a hospital in that city for the benefit of English residents and visitors. The estimated cost for erection and equipment of the new institution is £7000. Nearly the whole of this sum has been already raised. It is confidently hoped that the hospital will be ready for the reception of patients at the beginning of next year.

State Aid for Deaf-Mutes.—Various institutions in New York State for the care of the deaf now receive from the State $223,226 a year. There is a new educational bill pending in the State Legislature which seeks to compel the State to pay for the maintenance of all the pupils in schools for the deaf and blind. This bill, if passed, would add $200,000 to the above-mentioned expenses now incurred by the State.

A Physician's Gold Fetters.—One of the earliest fees for medical treatment of which there is any record is mentioned by Herodotus, who says that Darius gave the slave Democedes two pairs of gold fetters. The usual fee at that time in Greece was very small, about sixteen cents in our money, yet there were notable exceptions, as when King Antiochus paid $150,000 for medical treatment, and later, when the Emperor Claudian paid his physician about $20,000 a year. The latter was twice the annual income of the eminent physicians of that time.

Alkaline Glassware.—A German chemist calls attention to the fact that certain test-tubes, beakers, and the like, made in Germany, are so alkaline in character that they impart some of this quality to liquids placed in them. The vessels are said to be well made and to be of very clear glass but it is evident that they might easily be the source of serious error. They would be especially liable to mislead medical men who have not the means at hand of making control observations and might in certain cases give data that would be the source of uneasiness.

The Swiney Prize.—This has just been awarded to Dr. J. Dixon Mann, Professor of Forensic Medicine and Toxicology in Owens College, Manchester, for his work on "Forensic Medicine and Toxicology." The prize is a very valuable one (almost $1000). It consists of a silver goblet of the value of £100 and money to the same amount. The prize is given each alternate five years for works in English on general jurisprudence and medical jurisprudence. The award is made by a committee from the Society of Arts and the Royal College of Physicians of London.

Deaths from Ether as an Anesthetic.—In a review of Dr. Bell's pamphlet on "The Safety of Chloroform as an Anesthetic," the London *Medical Press and Circular*, January 25, 1899, states that there have been no less than fifty-four deaths from ether used as an anesthetic during the year 1898 in England alone. This is a strikingly large number, and is certainly more than the advocates of ether anesthesia usually admit into their statistics of the subject. Can our contemporary give the facts that

substantiate its statistics? The subject is a most important one.

Obituary.—Dr. Robert Harris, a well-known figure in Philadelphia medical circles, died at his home in Philadelphia, February 21, 1899. He was the son of a physician, the brother of William Harris, formerly president of Princeton College, and the grandson of Robert Patterson, a former provost of the University of Pennsylvania. Dr. Harris was born in 1822, and was the author of a number of articles in medical journals, and the editor in this country of "Playfair's Midwifery." In recent years he has been known for patient statistical research on the subject of Cæsarian section, extending his enquiries to the after-health of the mother and the length of life of children thus delivered.

New York as Seen in Vienna.—The *Klinische therapeutische Wochenschrift* of Vienna begins the year with an article on the epidemic of grip in New York. The writer says that owing to the undiminished spread of the disease the Board of Health was compelled to take extreme measures for its control. Among others he mentions the following: The fumigation of the street-cars, and the disinfection of all the mats and carpets in them; the closure of the Medical Department of Columbia University on account of the sickness of eight professors and numerous students; the closure of the Wallack Theater, and finally, the prohibition of kissing, though whether with or without a penalty was unknown to the writer.

Prevention of Tuberculosis Discussed.—A committee representing the International Congress for the Prevention of Tuberculosis, which will sit in Berlin from May 24 to May 27, 1899, under the patronage of Empress Augusta Victoria and the Honorary Presidency of the Imperial Chancellor, Prince Von Hohenlohe called recently at the United States Embassy to enlist American interest and cooperation in the undertaking. Dr. C. W. Stiles, scientific attaché to the United States Embassy, is preparing a report for the medical press on the scope and purpose of the congress, whose main object is to devise ways and means of combatting tuberculosis, especially as a popular scourge. Emperor William will entertain the members of the congress.

A Princely Surgeon Honored.—The far-famed ophthalmologist, Duke Carl of Bavaria, has recently been honored by an election to honorary membership in the Academy of Medicine of St. Petersburg. He has just passed his sixtieth birthday, and during the present winter has given a large share of his time to the conduct of his eye-clinic in Munich. His brother, Prince Ludwig Ferdinand, who is also a medical graduate, has lately been promoted to the rank of general of cavalry. He, however, only saw active service in the rank of lieutenant, while his brother, Duke Carl, commanded his wing of a cavalry regiment as major. Prince Ludwig receives patients in his palace in Munich, and is a visiting physician of the University clinic. On account of one of his children being ill with an infectious disease, he has refrained from all attendance upon social functions for a month or more.

An Unpardonable Fault and Its Punishment.—A telegram in the *Morning Leader* of London announces, according to the *Medical Press and Circular* (London), that Professor Wiggin of the College of Physicians of Chicago has been suspended from his professional chair because in one of his lectures on pathology he described woman as a "two-legged dyspeptic owl," and said that the "female form divine" is the climax of Nature's irony. One London contemporary remarks that "of course the women's clubs are up in arms at such an insult." It does not state the nature of the clubs the women have taken in their arms, but they should at least be studded with nails to avenge so dire an insult properly. It was somebody in the "wild and woolly" West who inflicted that other definition of woman on a long-suffering world "a constipated biped without feathers." Of course these ungallant remarks deserve condign punishment. We are glad our London contemporary takes the whole affair so seriously for, of course, it is for peccadilloes like this that we hire and discharge our medical professors in America, not for any supposititious scientific talents or attainments that they possess.

A Physician's Rare Good Fortune.—A decision in a Surrogate's Court at Kingston, N. Y., settles a dispute as to an inheritance of a quarter of a million dollars. It arose out of a will in which the testator left his entire fortune to his physician. It was disputed by the testator's half-sister who claimed it as being the nearest relative. The evidence showed that the testator was taken ill while spending a few days at a hotel at Kingston. He sent for a physician, who, in spite of the fact that his patient was poor and unable to pay full fees, watched him through a serious illness and gave him the most devoted attention. The patient after his recovery remained at Kingston to be near his physician whose kindness had won his affection. Quite unexpectedly, an uncle, who during his life had taken no notice of the patient, died leaving him his entire fortune. He was anxious then to show his gratitude to the physician and upon his death, which occurred recently, the latter discovered that his friend had left him the amount mentioned above. The reason assigned for the bequest is that the physician befriended him when he was poor and when all his relatives neglected him. The decision of the Surrogate upholds the will.

A Hygienic Decalogue.—We clip the following from the *Lancet* for February 11th: Dr. Decornet of Ferté sur Aube, France, is announced as the winner of a prize offered by the extensive and well-known publishing house of Hachette & Co. for the ten best maxims for preserving the health, which were to be published in the "Annual Almanac" issued by the firm. These are the prize maxims: (1) General Hygiene: Rise early, go to bed early, and in the meantime keep yourself occupied. (2) Respiratory Hygiene: Water and bread sustain life, but pure air and sunlight are indispensable for health. (3) Gastro-Intestinal Hygiene: Frugality and sobriety are the best elixir vitæ for a long life. (4) Epidermal Hygiene: Cleanliness preserves from rust; the best kept machines last longest. (5) Hygiene of Sleep: A sufficiency of rest

repairs and strengthens; too much rest weakens and makes soft. (6) Hygiene of Clothing: He is well clothed who keeps his body sufficiently warm, safeguarding it from all abrupt changes of temperature, while at the same time maintaining perfect freedom of motion. (7) Dwelling Hygiene: A house that is clean and cheerful makes a happy home. (8) Moral Hygiene: The mind reposes and resumes its edge by means of relaxation and amusement, but excess opens the door to the passions, and these attract the vices. (9) Intellectual Hygiene: Gaiety conduces to love of life, and love of life is the half of health; on the other hand, sadness and gloom help on old age. (10) Professional Hygiene: Is it your brain that feeds you, don't allow your arms and legs to become anchylosed. Do you dig for a livelihood, don't omit to burnish your intellect and elevate your thoughts.

SPECIAL ARTICLE.

THE "LANCET" AND QUININ IN MALARIA.

THE London *Lancet* of February 4th, before it had seen our answer, we suspect, comments approvingly on Dr. Hare's criticism in the *Medical Record* of our position with regard to the use of quinin in malaria and especially as to its use in black-water fever, malarial hematuria or hemoglobinuria. The *Lancet* considers that Dr. Hare is very sensible in echoing the caution which Koch has lately given with regard to the use of quinin in malarial hematuria, "a caution, indeed, which had been given before by many writers in America and especially by many physicians in the States."

Our views on the subject have aroused a good deal more attention than we anticipated. We do not pretend to any profound knowledge of the subject gathered from our personal experience. We stated practical conclusions for the benefit of the general practitioner based on the opinions of thoroughly conservative experts in the treatment of malaria.

We shall now quote more fully the authorities substantiating our position and ask a candid judgment as to whether it is not the only position possible for an unprejudiced medical editor to hold: Osler in the last edition of his "Text-Book" adds to his article on malaria the following clearly expressive paragraph which was evidently penned after consideration of the articles called forth by Koch's declarations regarding his experience in South Africa. "An interesting question is much discussed whether quinin does not cause or at any rate aggravate the hemoglobinuria. We have not yet seen a case in which this condition has occurred as a result of the use of the drug. It seems localized in certain sections and Bastianelli states that it is not seen in the Roman malarial fevers. He recommends that in any case of hemoglobinuria if the blood shows parasites quinin should be administered freely. In the post-malarial forms quinin aggravates the attack. In the active malarial infection the patient runs less risk with the quinin."

In the *Lancet* for December 24th there is the discussion of a case of malarial hemoglobinuria before the Pathological Society of London. Dr. W. H. Crosse says of his patient: "In spite of his improving under quinin he had a slight relapse of the hemoglobinuria which disappeared while he was having still larger doses of quinin." Dr. Crosse was until recently the chief medical officer to the Royal Niger Company of Central Africa. He has had an extensive experience with malarial hemoglobinuria including a number of attacks of the disease himself. He discussed this subject at the opening of the medical session at Guy's Hospital last fall (see *Brit. Med. Jour.*) and completely disagreed with Koch. He attributed his own attacks of malaria to his failing to take quinin. He tells the story of a friend who foolishly decided against the use of quinin and suffered a very severe attack from which he was saved only by the free use of quinin. He insists that his friends going to Central and South Africa shall have no foolish notions with regard to any possible harm produced by quinin during the course of the affection.

Dr. Moffat, principal medical officer of the Uganda Principality, writes to the *British Medical Journal* of September 24th as follows: "Professor Koch may be right when he says that quinin poisoning causes hemoglobinuria. I do not possess sufficient knowledge to criticise that statement. This much I will say, that after seven years in Eastern Equatorial Africa, during which time I have treated many hundreds of cases of malaria, I have never seen a man die of fever when quinin was given properly and early in the case. The fatal cases whether complicated with hemoglobinuria or not have all been those in which for some reason quinin was not administered, or was given in very small doses or else resorted to only when the case was practically hopeless.

"Out of nine cases of black-water fever which I have had two were fatal; in both the administration of quinin was neglected until too late. All the cases which recovered were treated with heroic doses of quinin with one exception. In this one case 30 grains of quinin were given in the twenty-four hours and the attack lasted four days, the hemoglobinuria subsiding gradually. In the other cases 60 to 120 grains in the twenty-four hours were given and the hemoglobinuria only lasted from twenty-four to thirty-six hours, stopping quite abruptly."

Laveran in the last edition of his book on "Paludism" says: "It is *always* necessary to resort to quinin for the treatment of acute paludism when we wish to break up the fever and especially in grave cases." Further on he continues: "The rarity of quinin hemoglobinuria shows that an individual predisposition is necessary for it. Malaria is only an accessory (adjuvant) cause. Sulphate of cinchonidine does not give rise to hemoglobinuria according to Pampoukis, and ought to be substituted for quinin in patients liable to it." Laveran, it may be seen, does not feel able, even in patients with an idiosyncrasy, to advise a radical departure from cinchona-bark treatment in some form.

Next we came to the question of the influence of quinin on the kidneys. The *Lancet* quotes with approval Professor Hare as saying that according to writers of experience quinin in full doses has similar effects (nephritis,

fatal malarial hematuria, and glomerulitis have been mentioned just above, and to all, or at least to some of these, the reference is made). "These effects are brought about by quinin producing renal congestion and inflammation." We should like to know some reliable authorities for this startling statement of the *Lancet*. If full doses of quinin produced renal inflammation Italy would be overrun with nephritis. So would all the malarial countries. The fact is that nephritis is no more frequent in malarial countries where quinin is used freely than it is elsewhere. Hirsch, the medical geographer, made a special study of this subject years ago, and his conclusions have never been contradicted. The *Lancet*, unwarrantably it would seem, is lending the weight of its authority to an opinion liable to do a great deal of harm when it states that quinin in therapeutic doses ever produces nephritis except in the rare cases in which idiosyncrasy exists.

Laveran discusses in his book (before mentioned) the complications to which the use of the salts of quinin may give rise. He mentions toxic symptoms, hemoglobinuria, icterohematuria, cutaneous eruptions, visual and auditory phenomena, and oxytoxic properties, but says not a word of nephritis. Rem Picci, who made a study of nephritis complicating malaria in Rome, and who has collected the statistics of over 7000 cases of malaria that occurred in the Roman hospitals during the last four years said in *Il Policlinico* last year:

"The treatment of the kidney affection (of malaria) is the same as that of the malaria itself. Quinin, which according to some authors, causes albuminuria and hemoglobinuria is not contraindicated, but on the contrary is indispensable. These symptoms occur with or after the malarial paroxysm and before the employment of quinin, they get worse with every new attack and disappear with the malaria itself after the energetic use of quinin."

We sincerely hope then that the omniscient editor who sits up aloft in the *Lancet* offices and dictates, without quoting his authorities, *ex cathedra* conservative opinions to an inexperienced medical public, will let us share in the special illumination on this subject vouchsafed to him. The subject is an extremely interesting and important one. Let us have the facts and the figures to demonstrate why we should hesitate to use full therapeutic doses of quinin whenever there is active malaria despite the presence of nephritis, of albuminuria, or of hemoglobinuria. As far as our researches into the literature of the subject go the authorities, who speak from experience, are on the other side.

For Obstinate Constipation in Acute Meningitis the following mixture is recommended as suitable for administration to a child:

℞	Ol. tiglii	*m.* ii
	Mucilag. tragacanth.	q.s.
	Syr. zingiberis	ʒ i
	Aq. dest.	℥ ii.

M. Ft. emulsio. Sig. One to two tablespoonfuls every fifteen minutes until the bowels act.—*Barthez* and *Sanné*.

CORRESPONDENCE.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

A NOTE ON THE PRACTICAL USE OF HYPNOTISM—THE DIAGNOSIS OF ACUTE TUBERCULAR INFECTION FROM PNEUMONIA AND TYPHOID FEVER—SOME RECENT CHARITIES—HOSPITAL NOTES—PERSONAL NOTES—OBITUARY—HEALTH STATISTICS.

PHILADELPHIA, February 28, 1899.

AT a meeting of the Philadelphia County Medical Society held Wednesday evening, February 22d, Dr. J. Madison Taylor read a paper, entitled "A Note on the Practical Use of Hypnotism." Hypnotism is earning a place as an auxiliary to medicine and when its halo of humbug is removed it will be used more. The chance danger to be feared is that the physician using it will be branded as a charlatan—of danger to the patient there is practically none.

Dr. Taylor, after obtaining the consent of his patient, closes the eyes and finds that this is sufficient if he has the cooperation of the patient to the point of actual impulse. Among the successful cases he has treated were those of subjects suffering from alcoholism, the drug-habit, hysteria, insomnia, hysterical paralyses such as deafness and blindness, and from disorders due to disturbed functions. Several cases were detailed and in one patient Dr. Taylor said he had tried the effect of hypnotism upon the vasomotor system with the following result: He suggested to the hypnotized patient that one hand be cold, the other warm; this being successful he suggested that the cold hand be now warm and the warm hand cold, which he claimed was also successful. He then exhibited a girl, whom he called "the residuum of the gynecologic art," who was quickly put in a condition of apparent sleep and as easily wakened. Dr. Taylor said he would not pretend to give any explanation as to how the phenomenon occurred or why.

Dr. Charles K. Mills discussed the question and said that while he had brought the subject to the Society's notice some twenty years ago he had never had much success with it and while he could not say it was of *no* value, he thought its use limited and doubted if any permanent good follows its use in alcoholism- and drug-habits or if it is ever of value in melancholia.

Dr. Francis X. Dercum expressed views similar to Dr. Mills' and spoke also of the hypnotic-habit which those hypnotized frequently develop, a habit in which they bother the hypnotizer by continually wishing to be hypnotised. His explanation of the phenomena is that the neurons retract their processes, or means of connection, as they do in sleep, except those used for the sense of hearing. The neurons are made to retract these processes by fatigue on the part of the patient, induced either by staring at some object or by thinking intently on some one subject. He believes too that "conscious suggestion," when all the channels to the brain are open, should and does accomplish more than hypnotic suggestion when only one channel, that of hearing, is open.

Dr. Charles W. Burr then gave a history of mesmerism and hypnotism and quoted many clever tricks used by charlatans and others to deceive the public and as an example asked what evidence there was to show that Dr. Taylor's patient was not shamming. He did not deny hypnosis but agreed with Dr. Dercum and Dr. Mills in believing that very little if any good is accomplished by it.

The question was then discussed by Professor Newbold of the University of Pennsylvania, and Dr. Orville Horwitz, who said he had removed tuberculous glands of the groin from a professional hypnotizer's assistant without the aid of any anesthetic after the patient had been hypnotized by the professional. Dr. Hare related some observations made by himself and Dr. Martin when doing some experimental work with hypnotism on animals. Dr. Daland believes it should be against the law to practise hypnosis.

The Veterinary Department of the University of Pennsylvania has received a legacy of $5000 by the will of the late Josephine Lippincott and St. Agnes' Hospital and St. Mary's Hospital each $1000 by the will of the late John H. Mullin. Mrs. Elizabeth L. Devine has left an annuity of $1000 to the sisters of St. Joseph's Hospital, and the residue of her estate after other bequests are paid is to be divided among St. Mary's, St. Agnes', the Episcopal, and the German Hospitals.

An addition to the Easton Hospital, costing $12,000, increasing the total number of beds fifty-four, was opened on Washington's Birthday. There is also a childrens' ward containing twelve beds.

Professor William Libbey of Princeton on Washington's Birthday gave an illustrated lecture on the Peary Relief Expedition to the students of the Jefferson Medical College.

Dr. J. Chalmers DaCosta has been appointed surgeon to St. Joseph's Hospital in the place of Dr. John H. Packard who has resigned.

Dr. Matthews of Louisville, President of the American Medical Association and Dr. Long, Professor of Therapeutics at the University of Buffalo, were introduced last week by Dr. H. A. Hare to the senior class of Jefferson Medical College to whom Dr. Matthews made a brief address on the duties of the physician.

The number of typhoid-fever cases has again increased to an alarming figure, no less than 421 *new* cases having been reported this week against 287 the week before, an increase of 134. The total number of deaths occurring in Philadelphia during the week ending February 25th, as reported at the Health Office, was 618, an increase of 91 over the previous week and of 150 over the corresponding period of last year. The total number of new cases of contagious diseases was 506, reported as follows: diphtheria, 52 cases with 16 deaths; scarlet fever, 33 cases with 1 death; typhoid fever, 421 cases with 38 deaths.

Health Report, New York City.—For the week ending February 25th: Diphtheria, 184 cases, 24 deaths; scarlatina, 170 cases, 18 deaths; tuberculosis, 281 cases, 194 deaths; typhoid, 18 cases, 7 deaths.

MEDICAL MATTERS IN CHICAGO.

[From Our Special Correspondent.]

METHODS OF CHILD-TRAINING—CHARTER OF INDEPENDENT MEDICAL COLLEGE REVOKED—FILARIA SANGUINIS HOMINIS—SKELETON IN MEDICO-LEGAL ANATOMY.

CHICAGO, February 26, 1890.

THE Chicago Board of Education will be asked to take the initiative in new methods pertaining to child-training. A proposition has been made to ascertain the physical endurance of the children in the public schools by Dr. W. S. Christopher. It is based upon the theory that at certain ages children are more liable to fatigue than at others, and that during such periods the requisite is comparative rest. Investigations by Dr. W. O. Krohn of the Hospital for the Insane at Kankakee, conducted among 32,000 children, have indicated that at the age of eight years the fatigue period of a child is at its highest. From that age it decreases. Investigation also shows that the fatigue-period recurs in cycles during the day, generally in the morning between the hours of ten and eleven. If these results are substantiated by the tests which Dr. Christopher hopes to have introduced into the Chicago schools, some changes in the course of study will present themselves as necessary. It will seem advisable to have the studies of the third grade, which the child reaches at the age of eight years, made lighter, and to have the lighter instruction of the day come at the hours at which the fatigue is noted to be the greatest. The tests consist of measurements, weighing, and of the enduring power of the muscles.

Diplomas entitling their holders to practise medicine are no longer to be issued by the Independent Medical College of this city, unless the judgment recorded recently in Judge Baker's court is overruled by the Supreme Court. The court finds the defendant college guilty of issuing illegal diplomas, as charged in the quo warranto proceedings, and has revoked the charter of the institution. It is said that motions for a new trial and for arrest of judgment were overruled, but an appeal to the Supreme Court was allowed.

At a meeting of the Chicago Medical Society, held February 15th, Dr. J. O. Nelson read a paper on the subject of filaria sanguinis hominis, and presented two mounted specimens of the hematozoon which were in the chylous urine of the patient. The case is of peculiar interest inasmuch as the patient has always been a resident of the United States, having been as far South as Florida, but never having been in a foreign country. The history is as follows:

Mr. R., aged sixty-six years, a resident of Indiana for the past thirty years. Previous to this was a resident of Ohio. In the latter State he was afflicted with malarial fever of the intermittent type to a severe degree, and was only relieved by change of climate when he moved to Indiana. No date of infection can be discovered except mosquito-poisoning, malaria, or the fact that nearly ten years ago he drank from a well which contained dead organic material and which caused him to immediately vomit, showing its extremely poisonous character. Early

in 1898 the patient had a severe attack of catarrhal jaundice, which jaundice was very slow to disappear, and was attended with enlargement of the liver. Early in the fall of 1898 the patient was attacked with a violent impetigo, together with an extreme hyperesthesia of the skin. There also developed a peculiar form of darting pains which occurred in any part of the body, or extremities, only lasting a few seconds, but being knife-like in character.

The patient is a well-preserved man; has absolutely no specific history, and is of very temperate habits. Physical examination shows internal organs normal, except for a little tenderness over the gall-bladder. Lymphatic swellings exist on the ankles with a tendency to break down, and abscess. Periosteum over both tibiæ thickened, the ankles edematous. During the past summer the patient developed a tendency to drowsiness to such an extent that he has trouble to keep awake during the daytime, this being entirely unnatural as he is of an energetic and active disposition. Several times last summer he noticed that he had no desire to micturate from morning until night, and the edema of the ankles increased. About November 1st his first hematuria occurred in the evening, and the next day the urine was of a chylous character, but Dr. Nelson found no filaria in these specimens. The first specimen of urine he examined was milky, specific gravity 1020, alkaline, and in each drop of the precipitated specimen from one to three active worm-like bodies, in constant motion, from 1/100″ to 1/200″ in length, easily examined under the low power, and these worm-like bodies he pronounced to be the embryos of filaria sanguinis hominis. Up to the present time he has not succeeded in finding the female parent worm.

At a recent meeting of the Chicago Medico-Legal Society, the subject of the skeleton in medico-legal anatomy was discussed, and the most interesting feature of the discussion was the remarks of Dr. William T. Eckley, who, in part, said: (1) There is no difficulty in identifying human bones if the whole human skeleton be present, anthropoid to the contrary notwithstanding. (2) The smallest fragment of bone can be identified microscopically even in the absence of Haver's canals. (3) In case of fragmentary bones the medical expert should advance no opinion as to the precise origin, but content himself with stating whether or not said fragments are bone. (4) If there is firm bony union of all the epiphyses, if the greater number of the emissary foramina are closed, if the constant foramina are shown to exist, if the secondary foramina are demonstrable, if the bones are solid and their muscular attachments well marked, then our conclusion is, these bony remains are of an adult human being. (5) In the determination of sex the pelvis is the chief guide, but little or no evidence is furnished by the pelvis before puberty. After puberty, even when the entire pelvis is recovered, only a very guarded opinion should be given as to the sex of the individual. (6) The prognathous skull of the negro, the pyramidal skull of the Asiatic, and the oval skull of the Caucasian, wanting in marked prominences and undue compressions is everywhere conceded in determining racial generalizations.

Conclusions.—(1) Given a sexually known skeleton, certain minor differences are found in the majority of cases between male and female skeletons; but given a sexually unknown skeleton, these minor differences become probabilities only subject to such grave exceptions as to render testimony practically useless, bombastic and even dangerous in forensic medicine. (2) While the pelvis is the chief guide in determining sex, still evidence founded thereon can be no more than presumptive and circumstantial, a bad variety of the poorest class. (3) In identifying individual bones, at least some one well-marked characteristic point should be present to make good evidence. Each bone has characteristics. Fragments of bone possessing characteristic features of individual bone make reliable testimony. A femur may be identified by a fragment no bigger than a dime, providing the tereal impression is present. The lacrimal crest, the vidian canal, the facial canal will identify respectively the bones to which they belong. The absence of characteristic markings makes medical testimony more culpable and far more dangerous than the average homicide. (4) Transition from compact to cancellous bone is easy, logical and gradual. (5) Pneumatic cancellous bone has a demonstrable lining when recent. Its irregular smooth cells cannot be mistaken for cancellous non-pneumatic bone tissue. (6) The practicability of introducing bones in the identification of sex is questionable, since some females are skeletally male and vice versa; such testimony is pernicious since the bone offered in evidence may have been of this class. (7) If sex can be identified by a fragment of bone, why cannot the liver and stomach, the heart and appendix, the kidney and brain be introduced in evidence with even greater propriety? These are studied both microscopically and macroscopically much more exhaustively than bone. Still in all the annals of law and medicine no such precedent can be found. (8) Sesamoid bones are in shape, constancy and development the most variable bones of the skeleton. They owe their existence to heredity, their development to muscular action. The shape of the articular surface corresponds inversely to the shape of the articular surface of the bone with which it articulates. Sesamoids are found in the tendons of some muscles where transmission of power is needed with maximum mechanical advantage, *e. g.*, the patella or knee-pan, the two in the flexor brevis hallucis pedis, and in the flexor brevis hallucis manus, in the peroneus longus. They bear no definite proportion to the size of the individual, since an adult of 150 pounds, who has used the sesamoidal areas much, may have larger sesamoid bones than one of 300 pounds, who has used this area little. The articular surfaces are lubricated by synovia, and are frequently the seat of subacute inflammation. As a class they have a very limited blood-supply. Sesamoid bones lose much of their specific character when subjected to the cleaning process. Logically sesamoid bones of the foot are larger in people who wear no shoes, free action of the foot increasing the activity of the sesamoid area and consequently aiding the development of the bone, since growth is the correlation of function.

The much-used feet and hands of a relatively small woman may have larger sesamoids than the little-used feet of a large man, and conversely. The idea of determining sex by sesamoid bones for medico-legal purposes is preposterous, illogical, and unscientific. The blood-supply of sesamoid bones like the blood-supply of tendons to which they morphologically belong, and of which they form an integral part, when present, is limited; hence, growth-changes are slow in these bones of necessity. For practical purposes, *viz.*, identification of sex, tight trousers, tight shoes, tight gloves, introduced in evidence as having a bearing on the modification of sesamoids should disqualify the medical jurist. (9) The temporal bone. In the criminal case of the State of Illinois *vs.* L. A. Luetgert, the alleged temporal bone of the State was in his opinion neither a temporal bone nor any part of a temporal bone, because: (1) It had parts and appearances inconsistent with a temporal bone. (2) It had not a single characteristic of this bone. When one recalls the numerous markings by which this bone is easily identifiable, as the internal ear, the ossicles, the styloid, the auditory meatuses, the glenoid, the canalia muscula, tuberarius and carotid canal and remember their absence in the alleged temporal bone, it would seem like lunancy to call this a temporal bone. Just as well might one swear to the identity of a coat, when every intrinsic vestige of the garment had disappeared except a buttonhole. The alleged facial canal in the petrosa, containing the alleged facial nerve had neither the direction, size, shape, peculiar caliber nor environment of a facial canal. The medical jurists of the State saw no sexual marking in this canal. On microscopic examination this canal contained vegetable fiber, not a facial nerve with petrosal branches. (10) The alleged human femur was in his opinion not a femur, because evidence was clear, judging from the specimen, that the bone to which this specimen belonged was far shorter than any known or recorded hnman femur; the thickness of the wall was far below the average; the medullary canal did not take the proper direction and was withal much too small; everything by which to identfiy a human femur was absent except the medullary canal; nothing by which to identify the bone as human was present.

OUR LONDON LETTER.

[From Our Special Correspondent.]

CRITICISM OF THE GENERAL MEDICAL COUNCIL—ORGANIZED EFFORT AGAINST THE CONSCIENCE CLAUSE OF THE VACCINATION ACT—THE NEW LONDON POLYCLINIC—ORIGIN OF THE PLAGUE IN TURKESTAN.

LONDON, February 16, 1899.

THE echoes of the Hunter "apothecary-physician" suit are still reverberating. The journals are full of indignant letters from members of the profession, and it is talked of everywhere that doctors congregate, the general and unanimous verdict being that the Penal Committee would have been much better employed in disciplining some of the quacks and unqualified practitioners who swarm under their very noses. Their dulness of vision and supineness in the Nugent impersonation case are mos unfavorably contrasted with their petty officiousness and zeal in prosecuting poor Mr. Hunter for a mere error of medical etiquette.

On the other hand the L. S. A. is loudly demanding, if he is not permitted to term himself physician, upon what ground can the possessor of an M. B. or M. R. C. S. degree be allowed to term himself "doctor," and their reasoning is logically sound. The episode seems likely to do much good in ventilating the rank absurdities of the chaotic condition of English medical qualifications.

An organized movement has already been set on foot in the profession looking to the repeal of the new and infamous Vaccination Act of last year. The spectacle of 270,000 children granted exemption from vaccination already is certainly enough to damn the Conscience Clause without further trial and to raise the gravest apprehensions as to the mischief already done, and its effects upon the next smallpox epidemic. The Worcester Branch of the British Medical Association at its last meeting adopted formal resolutions demanding the repeal of the present act, the substitution of the old law, and an additional provision rendering revaccination between the ages of fourteen and sixteen compulsory. Copies of these have been sent to every other branch in the United Kingdom for their action. It will be remembered that the chief condition upon which the Government obtained the consent of Lord Lister and other prominent medical men to their late "experiment" was the promise of speedy legislation for promoting or enforcing revaccination. That promise ought to be promptly fulfilled, but we fear it will serve as a block to any more-radical action until full time has been given to the Government to make it good. Several of the boards of guardians, corresponding to our county supervisors, have become alarmed at the results of the Conscience Clause and actually forwarded petitions to Parliament for the repeal of the late Vaccination Act. The Kingston Board went further and voted that in future no applicant for employment in the workhouse or upon its staff should be appointed unless he could give satisfactory proof of successful vaccination.

It is reported that the authorities of the University of Cambridge are desirous of inducing Professor Adami of Mc Gill University to abjure his adopted country and return to Cambridge to take the Chair of Pathology made vacant by the death of Professor Kanthack.

A book was published a few weeks ago by one E. A. Heath, M.D., "Doctor of Medicine of the Hahnemann Medical College of Philadelphia (by Residence and Examination)" as he describes himself on the title-page, whose nationality can be readily judged by its title: "Vaccination or Blood-Poisoning with Animal Diseases." Copies were sent to the papers as usual most of which paid no attention to it, but the one great London daily which had been an ardent supporter of the Conscience Clause honored it with a pointed and most destructive review of nearly a column, pointing out a few of its most egregious misstatements and fallacies. One is worthy of mention as a sample, "Vaccination with cow-pox or grease is one of the first and foremost causes

of the increase of the various forms of consumption," which, in view of the marked *decrease* of nearly forty per cent. in the consumption death-rate suggests that if this is the kind of an "increase" caused by vaccination we can hardly have too much of it. We had no idea vaccination was such a panacea until Dr. Heath revealed it to us. To crown the climax of the rebuke and add insult to injury a curt editorial note was appended at the bottom of the column to the effect that the review had been written by a competent physician and expert, and the columns of the paper were not open for a further discussion of the subject! This, of course, brought a deluge of letters from furious "antis," accusing the paper of deserting its principles, to all of which the editor briefly replied that his principles were as sound as ever, but that he didn't propose to interfere with the freedom of reviewers whom he regarded as competent. So there is gruegruesome burbling in the antivaccination camp.

When John Bull once gets waked up and started to move the momentum of his own inertia carries him far and fast. The movement for the prevention of consumption is spreading steadily every day. Upon the medical side the latest development is the action of the Society of Health Officers in urging that tuberculosis should be a notifiable disease. But the Englishman's well-known tenacity of and jealousy for personal liberty and rights will pretty certainly prevent any such step for some time to come at least. On the side of the public a most sensible arrangement has been entered into between the farmers and butchers of one of the large market-towns in reference to tuberculous cattle. It was agreed that at every sale of a beef-animal both buyer and seller should pay a small sum into the hands of a joint committee and thus form a sinking fund out of which compensation should be paid for all beasts found to be diseased upon slaughtering.

The first formal meeting of the subscribers to the new London Polyclinic and Medical Graduates' College was held recently and was most successful. Nearly 300 medical men were present and the cordial support of the profession seems now assured for the new enterprise. Sir Wm. Broadbent was elected President of the Board of Governors and an Executive Council of twenty selected which contains some of the most prominent men in London. At a meeting of the council early this week it was decided to defer the opening of the college till April or early in May in order to give more time for the fitting up of the laboratories. This delay was urgently opposed by a strong minority of those who have done most to bring the enterprise to its present advancement and will be a great disappointment to many visiting American and other medical men now in London. But the allurements of a formal opening with solemn ceremonies and everything in apple-pie order for inspection by the world appealed too strongly to the majority of the council. It seems almost a pity in view of the fact that the scheme has been in process of incubation for nearly a year that a beginning could not have been made at once with the abundant clinical material at hand and the laboratory courses started one by one as their equipment was completed. The strength of the polyclinic is going to lie chiefly in its clinics and clinical consultations and lectures, and it will take months after these are actually started to get the full current of patients required properly flowing in their direction.

A most interesting story of how the plague came to Turkestan last autumn has just been told in the *Times of India* by a Russian baron. The outbreak was confined to a little mountain village but raged there with great fury, attacking no less than 381 of the 500 inhabitants and *killing all but three* of those attacked. This is a significant reply to those who claim that the disease has lost its virulence since the Middle Ages. Where it finds plenty of dirt it is as fatal as ever. Suddenly there appeared upon the scene a good angel in the shape of Dr. Lieven, an expert returning from Bombay with a supply of Haffkine's prophylactic serum and ordered to the smitten village by the Russian Government. All the survivors, about 120 in number, were promptly inoculated, and to the delight of all concerned the plague was stayed, no new cases developed, and the last death occurred on the fourth day after Dr. Lieven's arrival.

This was the part of science; what was that of religion? Upon careful investigation the whole frightful epidemic was traced to some sacred relics purporting to be the coverings of the tombs of saints brought back from a pilgrimage into Northern India by a holy man of the village, named Pir Isa. These rags had been handed over to a widow in the village to be cut up and made into amulets for the faithful, and this poor woman was the first victim of the plague. Shortly after the woman who had nursed her died, and then in rapid succession seven of her relatives. But the dangers of holiness were not over yet. Pir Isa was, of course, consulted in the matter, and he gave judgment that the relatives had been smitten because the widow had not been buried in the proper position enjoined by sacred law, and the only thing to be done was to dig her up and plant her properly, which was accordingly done, with the cheerful result that every one who assisted in the operation was smitten and died. If they had planted the old fakir and his filthy rags "in the prescribed position" it would have been more to the point.

A melancholy instance of the descent from the sublime to the ridiculous has been afforded by the death of one of the Lancers who took part in the celebrated cavalry charge at the battle of Omdurman. He was wounded and on the return of the regiment to England was sent to the Army Hospital at Netley. Last Thursday afternoon he was discharged as cured and sent home on furlough, and on Friday morning was found dead in one of the compartments of a railway carriage with an empty whisky-bottle by his side. Two other soldiers were with him, also unconscious, but only dead drunk. The finding of the post-mortem was, "Cause of death, acute alcoholism with partial asphyxia." There seemed little question that death had occurred in a debauch after long-enforced abstinence, partly from the effect of large amounts of alcohol upon his weakened constitution and partly from getting

raw spirit into the air-passages while drinking it out of a bottle with a drunken-man's recklessness.

TRANSACTIONS OF FOREIGN SOCIETIES.

German.

THE THERAPEUTIC VALUE OF CATHETERIZATION OF THE URETERS—DISCUSSION OF THE PAPER BY ISRAEL, LANDAU, KUTNER, POSNER, RICHTER, MAINZER, WOSSIDLO, AND OTHERS—PHLEBITIS AND THROMBOSIS.

THE closing meetings of the year of the Berlin Medical Society were largely taken up with a discussion of the therapeutic value of catheterization of the ureters. CASPER read the first paper upon this subject, including in it a description of three cases which had been cured by means of ureteral catheterization. Two of the patients suffered from a unilateral pyelitis, which was cured by repeated irrigation of the pelvis of the kidney with 1 to 1000 nitrate-of-silver solution by means of a catheter in the ureter. The other patient had a ureteral stone, which caused absolute cessation of urinary secretion for thirty-four hours. A catheter was passed into the ureter, and 1.5 ounces of oil were injected into the ureter with considerable force. Within an hour the patient passed twelve ounces of urine, and within the next fifteen hours more than six quarts. The stone was also passed into the bladder, and crushed and washed out. Such a fortunate result was not to be anticipated in every case, but at least the passage of the catheter gave the operator the knowledge of the exact situation of the stone. In cases of pyonephrosis a cure is most likely to take place if the interior of the kidney is so disposed that every part of the affected surface is accessible to the silver solution. This is more apt to be the case if the diagnosis of pyelitis is made in the early stages, and this is best done by separating the urine from the two kidneys before examination. It is a well-recognized principle that one kidney should not be removed until the functional capacity of the other has been determined. From one-fourth to one-third of the patients upon whom nephrectomy has been performed have died with symptoms of anuria or uremia. Several fatal cases have been reported in which the extirpated kidney secreted all the urine, the other being absent or functionally dead. Much has been said of the danger of ureteral catheterization. This point has surely been exaggerated. Albarran, Pasteau, and the writer have together made over 1500 ureteral catheterizations without setting up infection in a single instance. Still the procedure is a delicate one, and should be carried out with the greatest precaution.

ISRAEL thought that the views held by Casper were far too sanguine. He cited cases in which infection had followed close upon a catheterization of the ureters, and others to show that the examination of small quantities of urine obtained by means of the ureteral catheter is no sure guide to the functional capacity of the kidney. Moreover, if dependence were placed upon such examinations the golden period for the extirpation of a badly diseased kidney would sometimes pass by. He had removed a tuberculous kidney from a patient whose other kidney was also affected, and had thereby given an eight-months' lease of life to an individual who, unless the source of pyemic infection had been thus promptly removed, had scarce a week to live. The records of autopsies were also quoted to show the unreliability of conclusions drawn as to the permeability of the ureter, and the character of the kidney disease, as well as the hopelessness of trying to effect a cure by irrigation in most cases of renal pyelitis. One-third of his cases of pyelitis, for example, were associated with renal calculus.

LANDAU spoke of the catheterization of the ureters in connection with gynecologic practice. After testing the methods of Simon, Pawling, Kelly, and Casper he was convinced of the superiority of sight over touch in the passage of a catheter into the ureter, as time was thereby saved and damage to the mucous membrane avoided. The catheter is of the greatest value to the gynecologist, as by it the site of the ureter can be marked out during an operation for removal of the uterus or adnexa, or it may be passed at the end of such an operation in order to prove that the ureters have not been included in the ligature, or its presence in a fistulous ureter may reestablish the continuity of the canal, or its occasional passage may relieve a stricture of the ureter.

KUTNER said that it is not surprising that infection sometimes follows the use of ureteral instruments, as it is impossible to sterilize them. They cannot be subjected to heat without injury, and chemicals work to a great disadvantage in such slender tubes; and even if perfect sterilization could be obtained, there still remain the chances of carrying upward gonorrheal or other infection from the bladder or urethra.

POSNER spoke of the difficulty in determining the condition of the "other" kidney. He objected to the use of the phrase "normal average excretion" of urea, citing the case of a woman, one of whose kidneys was removed thirteen years before. Examination of her urine showed the amount of area secreted, within a short period of time, to vary from 15 to 29 grams. The variation was due to changes in the diet. It is necessary to estimate the amount of albumen ingested and excreted in urine, and in the stools before one can say with propriety that a kidney is or is not doing a normal amount of work.

RICHTER said that the variation in the excretion of urea is especially marked in the case of a nephritic kidney, such as the "other" kidney is apt to be. He thought it impossible to determine by either chemical or microscopical examination of the urine whether a kidney has the required amount of functional capacity. This can, however, be told by the examination of the blood according to the method of Koranyi. The method is a simple one, consisting in determining the variation in the freezing-point of the blood, the variation from the normal showing the amount of retained products of metabolism. In order to learn how much of the work is done by each kidney, it is only necessary to collect and examine the urine from each kidney for twenty or thirty minutes, for tests have shown that normally the two kidneys excrete almost exactly the same amounts of urea, chlorids, etc., if the

urine be collected for not too short a time. By comparing the result for either kidney, within the twenty-four-hours' product of both, one can readily determine what part of the total functional activity is to be credited to either organ.

MAINZER called attention to the fact that the ureter is not easily infected, as shown by its freedom from disease when both the kidney and bladder are affected. The kidney, like the bladder, is easily infected. One ought, therefore, to be very careful not to pass a ureteral catheter into the pelvis of the kidney except for the purpose of irrigation. For diagnostic ends this should never be done, as nothing can be gained thereby, and the risk of infection is much increased.

WOSSIDLO thus summed up his views upon the catheterization of the ureter as a diagnostic measure: It surpasses all other means of diagnosis in certain difficult cases of stone in the ureter, and also in light cases of pyelitis, with only slight clouding of the urine. In all other renal troubles it gives no information which might not be obtained by other methods less severe. It is in such cases, therefore, unnecessary, and it may be dangerous. The proof that one kidney produces normal urine is no proof that it will do so after the other kidney has been removed, a statement which has been substantiated by several fatal cases of nephrectomy.

In conclusion, CASPER warned against the mistake of confounding *post hoc* and *propter hoc* in the matter of ureteral catheterization. He mentioned the case of a young man who had an elevation of temperature after catheterization, which was hastily set down to the passage of the instrument, although the information was later secured from his physician that he had had for some time slight symptoms of pyelitis. He had previously shown the same elevation of temperature after the passage of a catheter into the bladder. In respect to the uncertainty of the conclusions which one is able to draw from the examination of small quantities of urine drawn from the catheters, Casper said the variations in health are so slight that when in diseased conditions one finds one kidney doing more than the normal amount of work, while the other is doing only a third or a fifth of the normal, there should be no hesitation in saying that the results of examination showed something that could be depended upon as to the relative functional capacity of the two organs.

At the College of Doctors of Medicine of Vienna, January 13th, MANNABERG discussed phlebitis and thrombosis, regretting the fact that so little attention is given to these subjects in text-books and lectures at present, while formerly they formed an important chapter. How important they are is shown by the fact that six per cent. of all autopsies performed in the general hospital of Vienna revealed the presence of thrombi. Of these 96 cases, 39 occurred in the course of an infectious disease, 30 in diseases of the heart or blood-vessels, 19 in neoplasms, 6 in senile marasmus, and one each in chlorosis and nephritis. A failure to make a correct diagnosis may lead the physician to recommend massage for the pain or swelling, thereby perhaps costing the patient his life. Thrombosis occurs most often in typhoid, influenza, tuberculosis, dysentery, diphtheria malaria, and cholera among the infectious diseases, less often in acute rheumatism, gonorrheal arthritis, scarlatina, smallpox, or measles. Virchow's theory that thrombosis occurs in infectious diseases on account of the failure of the strength of the patient has been much disputed, but as yet no one has proved the presence of bacilli in the thrombi. Another point for his theory is the occurrence of the thrombosis in most instances at the end of the disease, when the heart's power is much reduced. Bacteria are not found in the thrombi which arise in connection with valvular diseases of the heart and in fatty heart. The edema which is so common in connection with carcinoma is usually attributed to marasmus. It is really often due to the presence of thrombi. The pathology of thrombosis of chlorosis and leucemia is not clear. In these diseases the danger of a mistaken diagnosis and treatment is particularly great. Thrombosis after operations was also mentioned.

SOCIETY PROCEEDINGS.

HARVARD MEDICAL SOCIETY OF NEW YORK.

Stated Meeting, Held January 7, 1899.

THE President, P. C. COLE, M.D., in the Chair.

DR. THEODORE DUNHAM read the paper of the evening, entitled

SOME PRACTICAL POINTS IN THE PHYSICS OF STEAM-STERILIZATION.

(See page 257.)

DISCUSSION.

DR. E. M. FOOTE expressed himself as much interested in the paper and wished to know what were the best sterilizers on the market.

In order that the merits of the two principal sterilizers, the Kny-Sprague and the Bramhall-Deane, might be presented, representatives of both were asked to speak.

MR. BRANDT described the Kny-Sprague "Perfection" Sterilizer. The principle upon which it is constructed is the combination of a high temperature dry-air chamber with a high-pressure steam disinfecting-chamber. In other words, all material to be sterilized in this apparatus is subjected to dry heat at 250° F. (120° C.), and then to a current of steam of one atmosphere (fifteen pounds). This is accomplished by means of the annular jacket which surrounds the sterilizing-chamber. Steam is generated in this jacket, the safety-valve is set at fifteen pounds pressure, and a uniform temperature of 250° F. is maintained in the chamber. The temperature may be raised or lowered by adjusting the safety-valves. The air in the sterilizing-chamber is partly expelled by the high temperature, but, to make the sterilization more thorough and reliable, a vacuum is formed in the chamber by means of an air-ejector, which is worked by the steam-pressure contained in the jacket, or by the high-pressure steam of the house-plant if the apparatus be connected with the latter. A vacuum of from 20″ to 25″ can thus

be formed before steam is turned into the material to be sterilized, and in this way all dead spaces which may have formed are eliminated. The steam entering the sterilizing-chamber is then eagerly absorbed by the fabric which it penetrates rapidly and thoroughly. The temperature within the chamber being as high as that of the inflowing steam, no condensation takes place and therefore there is no wetting of the material in spite of the fact that the latter is thoroughly saturated by steam. If, however, it is desired that the dressings be absolutely free from dampness, drying can be accomplished by continuing the sterilization for about ten minutes longer in a dry vacuum-chamber as previously described. An apparatus which will sterilize by means of both steam and dry heat possesses a distinct advantage for animal suture material such as catgut and kangaroo tendon, which would be ruined by steam, may safely be placed in the dry chamber and subjected to a temperature sufficiently high to ensure complete sterilization.

MR. MAY described the Bramhall-Deane Sterilizer as consisting of a globe of copper or brass with a substantial circular door of cast bronze ground true against a flange of the same metal. The door is without a fastening or catch of any kind. It is absolutely steam- and air-tight from the pressure within and acts as a vacuum-valve to prevent possible collapse. It is a triumph of genius—economical and simple. The steam is supplied from a small generator or boiler placed a little below the globe, and entering from above drives the air out through the air-cock in the bottom of the globe, or through the open safety-valve at the top. This generator is furnished with a steam-coil, or burner for gas or petroleum heating, and has the advantage that should the fire be continued after the water has evaporated, the sterilizer itself will not be injured, merely the boiler, which may be repaired at a trifling cost. There is no cast iron in the whole apparatus. It is handsome, durable, and especially quick in operation where gas or petroleum is used for generating the pressure. It is furnished with a combination steam-gage and thermometer and safety-valve regulated to blow off at the proper temperature. It sterilizes perfectly and absolutely.

DR. COLE said he had examined both sterilizers and preferred the Kny-Sprague because it is possible to employ either steam or dry heat at will, because it has an air-ejector which creates a vacuum in the sterilizing-chamber before the steam is introduced, and because the sterilizing process occupies a much shorter time and there is a consequent large saving in heat.

DR. WHITMAN asked if it is absolutely necessary to have a vacuum in order to obtain complete sterilization.

MR. SPRAGUE replied that experiments have been made in which it was shown that steam will penetrate to the center of a mass of towels or gauze dressings much more rapidly and completely in a sterilizer from which the air has previously been expelled by the vacuum process. In one of these experiments a cake of ice had been wrapped in a blanket and placed in a sterilizer. After subjecting it to a temperature of 240° F. it was found that the ice was still unmelted. The same experiment was made with the vacuum process with the result that the steam penetrated the blanket and melted the ice. In another instance several eggs were wrapped inside of a lot of dressings and placed in the sterilizer. After subjecting them to a high temperature without the vacuum it was found that the eggs were still uncooked. The eggs were most thoroughly baked after being introduced into a sterilizer with the vacuum attachment.

DR. WALKER called attention to the fact that experimenters both in Germany and France have come to the same conclusions that Dr. Dunha n has reached, *viz.*, that it is necessary that the steam inlet be placed at the top of the apparatus and that sterilizers which are not constructed upon this principle must be inferior to those which are. He believed that Dr. Dunham was the first in this country to call attention to this important fact, and referred to the fact that among steamfitters it is well known that in setting up radiators the steam is always admitted at the top and the cold-air outlet placed at the bottom.

DR. BREWER stated that the most extensive and elaborate experiments have been made by Dr. Rowe at the Boston City Hospital in regard to sterilizers and as a result the Kny-Sprague has been adopted as the most satisfactory.

REVIEWS.

A TEXT-BOOK OF OBSTETRICS. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania. Philadelphia: W. B. Saunders. 1898.

THE reader of this scholarly work on midwifery will be inclined to ask Dr. Hirst to revise his preface in the next edition; he need make no apology for having written the book. It is a fresh, live contribution to the subject, written in a broad and catholic spirit, as with a learned pen, and gains by contrast to the various systems so much in vogue at the present day. Dr. Hirst has the experience, the facility of pen, and the knack of teaching; he knows how to separate the chaff from the wheat; the consequence is an admirable text-book of obstetrics, modern, scientific, convincing.

The subdivision of the work is much like that in most of the familiar text-books; but this cannot be avoided, nor is it uttered in criticism, for no man can create subjects. The views of the author are, after all, the interesting points. He prefers the Porro operation, for instance, to a Cæsarian section, where the latter operation is usually considered necessary. He induces abortion with metal dilators, premature labor with bougies. The immediate repair of the perineum is advocated, but not that of the torn cervix for the reasons of usual ignorance and aseptic unpreparedness. The chapter on puerperal sepsis is superb, and could accomplish immense good if it were universally studied, not merely read. It contains, by the way, for the first time in an obstetric work that we remember, a quotation from Holmes' immortal essay on "The Contagiousness of Puerperal Fever." It would be supererogation to speak of the scientific attitude of the

author in this chapter, for it is marked by the same breadth of conception and touch of scholarly genius which characterize the other parts of the book.

It is safe to say that if physicians took to heart the lessons imparted in this work the accusation could no longer be made that they, like the supposedly murderous midwife, are responsible for many puerperal deaths. For student and physician alike, this is one of the most satisfactorily written and clearly illustrated works on obstetrics, stamped with the authority of a man broadly grounded and trained, which has as yet been published. It will see many editions, for it deserves that distinction.

Traumatic Separation of the Epiphyses. By John Poland, F.R.C.S. With 337 illustrations and skiagrams. London: Smith, Elder & Co. New York: G. P. Putnam's Sons, 1898.

The author states that little note is made of epiphyseal separations in the standard books on surgery, consequently these accidents are continually mistaken for fractures and dislocations. He hopes that this work may call attention to the subject and induce surgeons to publish reports of cases of epiphyseal separations that may fall under their notice in the future.

Epiphyseal separations following the classification of Foucher and Bruns are divided into three groups: (1) Through the conjugal cartilage uniting the epiphysis with the diaphysis. (2) At the epiphyseal line, the conjugal cartilage adhering to the displaced epiphysis. (3) Juxta-epiphyseal separation, or fracture through the osteoid tissue or newly formed bone of the diaphysis. The first and second varieties are rare, and occur most often in young children; the third is the more common form. The author is in accord with previous writers and experimenters that epiphyseal separations are rare as compared with fractures, and that the liability to the accident is greater when ossification is well advanced in both the epiphysis and diaphysis, leaving a weak point at the cartilage itself: thus it is more common in the second decade of life and after puberty.

The cause of the separation is usually a twist or strain, particularly over-extension at a joint, by which the protecting periosteum is ruptured; and those epiphyses are most liable to the accident which are of large area, and to which unyielding ligaments are attached at or about the junction with the diaphysis. Thus, of the cases in which the nature of the injury was established by anatomic specimens or by autopsy, or when the separation was compound, or when operation was performed, as in 321 of the 693 cases recorded, the statistics are as follows: The lower epiphysis of the femur, 84, or about 26 per cent.; the lower epiphysis of the radius, 50, or about 15 per cent.; the upper epiphysis of the humerus, 49, or about 15 per cent.; the lower epiphysis of the tibia, 22, or about 7 per cent. The reports of unverified or "simple" cases number 372, and it may be doubted if they repay the author for the years of labor spent in collecting and transcribing them. For example, but four verified cases of separation of the head of the femur are recorded, and one of these (Kocher) was really a fracture, yet the total number reported is thirty-one. Many of the cases are ancient, and serve rather to illustrate the character of the evidence on which the diagnosis was made than to convince one that it was correct.

The especial interest in epiphyseal separations lies in the treatment, and in the possible effect of the injury on the subsequent growth of the limb. The difficulties in treatment are caused by the proximity to the joint, and by the fact that reposition of the fragments may be prevented by the torn and displaced periosteum. In such cases the open operation may be required. In rare instances, growth may be checked by the direct injury to the epiphyseal cartilage or by subsequent infection and disease, or by exuberant callus formation, but in nearly all cases asymmetry and deformity are due to displacement of the epiphysis. If accurate apposition of the fragments is attained the subsequent result will be precisely like that of a fracture.

The main purpose of the writer was, apparently, to produce a book of reference on epiphyseal separations, but it may be that the account of the anatomy and physiology of growing bones admirably illustrated by specimens and Röntgen pictures, the suggestions as to the possible effect of sprains and injuries at the epiphyseal region, and their influence in inducing secondary disease will be of even greater value to those who are interested in the surgical diseases of childhood.

The book is well written, well printed, and well illustrated, and the author and the publishers are to be congratulated on a work that is a distinct addition to surgical literature.

Manual of Chemistry: A Guide to Lectures and Laboratory Work for Beginners in Chemistry. By W. Simon, Ph.D., M.D., Professor of Chemistry and Toxicology in the College of Physicians and Surgeons, Baltimore; Professor of Chemistry in the Maryland College of Pharmacy. New (sixth) Edition. Illustrated. Philadelphia and New York: Lea Brothers & Co., 1898.

This work, now in its sixth edition, has become a classic in its particular line. Its numerous editions point to its excellence, which a careful examination verifies. Among the more recent discoveries we note with pleasure a sketch on argon and helium, the elements isolated from the air by Lord Rayleigh and Professor Ramsay.

Dr. Simon's vast experience as a teacher was no doubt made use of in the edition before us in following the classification he adopted in his former editions. The division of this vast science into seven heads is both logical and comprehensive, while the grouping of all strictly theoretical principles in a separate chapter, instead of being scattered throughout the work, is a most laudable feature. The section treatment of analytical chemistry, though brief, gives the student considerable acquaintance with this branch of chemistry, and both organic and physiological chemistry are presented in a manner most intelligible to the student or practitioner in search of a clear understanding of these subjects in a general way. The plates of color-tests enhance the value of the work,

which in its whole make-up as well, presents an inviting appearance, making it deserving of its reputation as a standard work on this subject.

A SYLLABUS OF MATERIA MEDICA. Compiled by WARREN COLEMAN, M.D., Instructor in Clinical Medicine and Materia Medica in Cornell University, Medical Department. New York: Wm. Wood & Co., 1899.

THIS is the handiest of the small materia-medica compends which has come to our notice. In addition to a complete list of the drugs, with their preparations, doses, actions, and uses, arranged alphabetically, the book contains a list of the more important preparations, and several regroupings of drugs according to physiological and special actions or effects. The book is complete in its way, yet condensed into a well-printed volume of almost vest-pocket size.

A PRIMER OF PSYCHOLOGY AND MENTAL DISEASE FOR USE IN TRAINING-SCHOOLS FOR ATTENDANTS AND NURSES AND IN MEDICAL CLASSES. By C. B. BURR, M.D., Medical Director of Oak Grove Hospital for Nervous and Mental Diseases, Flint, Mich.; formerly Medical Superintendent of the Eastern Michigan Asylum. Second edition. Philadelphia: The F. A. Davis Co., 1898.

THIS syllabus, arranged for the instruction of nurses in the outlines of mental diseases, with especial reference to the care of the insane, has found a sphere of usefulness as a hand-book for students. The text is brief, concise, and very elementary.

A LABORATORY GUIDE IN URINALYSIS AND TOXICOLOGY. By R. A. WITTHAUS, A.M., M.D., Professor of Chemistry, Physics, and Toxicology in the Medical Department of Cornell University; Professor of Chemistry and Toxicology in the Medical Department of the University of Vermont, etc. Fourth edition. New York: William Wood & Company, 1898.

THIS book is designed for the use of students working in college laboratories, but it can be used with profit by anybody engaged in chemical analysis. It is published in a very handy style and is printed on one side of the page only, so that a reference to any subject can easily be made. An elementary knowledge of chemistry is essential to those working with the book as the chemical formula is used in each instance instead of the full chemical name of the reagent. This, however, is of great advantage, as much space is gained, and the subject is condensed with profit. There are no unnecessary details given, simply a bare statement of facts throughout, consequently the beginner will require the assistance of his teacher until he understands the general manner in which the tests are made. After this the book alone will direct him sufficiently to enable him to carry out all the simpler procedures with accuracy.

The book fulfils the purpose for which it was intended and can be recommended as a safe guide to those engaged in this line of work.

THERAPEUTIC HINTS.

For Uremic Headache.—

℞	Potassii citratis	ʒ ii
	Spts. juniperi	ʒ vi
	Spts. etheris nitrosi	ʒ ii
	Inf. scoparis	℥ vi.

M. Sig. A wineglassful three times a day.

For Dyspepsia with Flatulence.—

℞	Tinct. gentianæ Tinct. valerianæ Tinct. nucis vomicæ	aa	ʒ i
	Chloroformi		gtt. xx–xl.

M. Sig. Ten to twenty drops in water before meals.

Care of Breasts before Confinement. — During the last month or six weeks of pregnancy the breast, especially at and near the nipple, should be prepared for functional activity in the following manner: At night inunctions with lanolin should be practised, and in the morning the parts should be washed for several minutes with soap and tepid water, a soft cloth being employed, and gentle friction. Then the entire breast should be washed with cold water and carefully dried.—*Mabbott.*

Orthoform with Calomel.—DANLOS has found it possible to make practically painless injections of calomel by means of the simultaneous use of orthoform. He employed the mixture in a case of syphilitic glossitis, and not only was analgesia obtained at the time of the injections, but on the fourth day when there is usually a painful reaction, only slight local discomfort was evidenced.

For Leucorrhea.—The following treatment is said to cause considerable improvement in the local symptoms, and in the general condition:

℞	Quininæ hydrobrom.	ʒ ss
	Ol. theobrom.	ʒ v.

M. Ft. suppos. No. X. Sig. One suppository is to be inserted into the vagina daily.—*Wright-Hardwicke.*

For Cholera Morbus.—During the early stage of active vomiting and diarrhea the following mixture will be found helpful:

℞	Ac. carbolici	gr. viii
	Glycerini	ʒ v
	Tinct. opii camph.	℥ ii
	Aq. cinnamomi	ʒ iii.

M. Sig. For an adult one teasponful after each paroxysm until they cease.

Ointment for Rheumatic Phlebitis.—

℞	Ac. salicylici	ʒ iv
	Morphinæ hydrochlorat.	gr. v
	Lanolini	℥ i.

M. Ft. unguentum. Sig. External use.—*Hirts.*

For Chilblains.—

℞	Chloroformi	ʒ ii

PARACENTESIS PERICARDII; REPORT OF A CASE.[1]

BY JAMES HAWLEY BURTENSHAW, M.D.,
OF NEW YORK.

UP to the end of the year 1896 exactly 100 cases of paracentesis pericardii had been reported[2]. Since that date, so far as my investigation of the literature bearing upon the subject determines, but seven additional cases have been placed on record, although it is probable that the operation has been performed more frequently than these statistics would indicate.

The history of the operation is exceedingly interesting. It is said that Riolanus suggested the advisability of tapping the pericardial sac in the presence of effusion as long ago as 1649, and that exactly 100 years later Senac also advocated the procedure, but no document exists to prove that either had the courage of his convictions. In 1806 Corvisart expressed the opinion that the operation was absolutely unjustifiable on account of its danger, but in 1819 Romero of Barcelona, in spite of this opinion, performed it three times, twice successfully. These are the first cases of which we have record. In 1839 Schuh, in Germany, tapped the pericardial sac twice in the case of a patient in whom the condition was later discovered to be a mediastinal tumor. In 1854 Trousseau, in France, reported several successful cases of his own and of Aran, and in 1866 the operation was introduced into England by Clifford Allbutt. A portion of a rib was resected and the pericardial sac opened and drained for the first time by Rosenstein of Leiden in 1881.

Probably the most complete paper on the subject of paracentesis pericardii is that by Samuel West, read before the Royal Medical and Chirurgical Society of London in 1883 and published in the *Transactions* of that year. In this paper the author states that up to the year 1866 79 cases had been recorded, the greater number in France, Germany, and the United States. In 71 of the cases in which sex was specified 57 were in males and 14 in females. A majority occurred before the thirtieth year of age, but 2 between the fiftieth and sixtieth years, and 3 between the sixtieth and seventieth. In only 1 instance in these 79 cases, and, indeed, in the 100 cases reported up to the year 1897, was the operation immediately fatal, the trocar penetrating the right ventricle and giving rise to hemorrhage into the pericardium which caused death in a few minutes. Of the remainder of the 79 patients 1 was moribund at the time the operation was performed and died two hours later, 6 died within twenty-four hours, 12 lived one week, 8 about one month, 6 for a period longer than one month but less than ninety days, 3 for a little more than six months, and 12 very much longer, while in the remainder, 30, or 38.4 per cent., recovery apparently was complete. In 16 of these cases the pericardium was tapped twice, in 3 three times, in 1 six times, in 1 eight times, in 1 many times during a period covering four and one-half years, and in 2 after the sac had been tapped twice a portion of a rib was resected and the pericardium laid freely open and drained. In 30 cases the fifth left intercostal space was selected for the insertion of the trocar, in 20 the fourth interspace, in 3 the sixth, in 3 the third, in 1 the seventh, and in 1 the eighth, the last being a dry tap. In a majority of the cases a point was chosen as near as possible to the left edge of the sternum, but in 3 the puncture was made to the right of the sternum, once in the third interspace, and twice in the fifth.

As compared with the immediately fatal case from penetration of the right ventricle, a case reported by Sloan in the *Edinburgh Medical Journal* for February, 1895, is of interest. Paracentesis was performed on a nineteen-year-old girl for pericardial effusion following an attack of rheumatism. The trocar penetrated the right ventricle and nearly ten ounces of blood was removed before the error was discovered by the surgeon. The patient made a good recovery. In this instance the trocar was introduced through the fourth interspace half an inch to the left of the sternum.

Primary pericarditis is considered a very rare condition and when met with children are usually the subjects. According to most authorities as a secondary affection it occurs most frequently in connection with rheumatism; in pulmonary tuberculosis, especially as an extension of tuberculous pleurisy; and during the course of chronic Bright's disease. The statistics of the 79 cases collected by West show that 13 of the patients had phthisis as a complica-

[1] Read before the West End Medical Society of New York, February 4, 1899.
[2] Meldon, *Med. Press and Circ.*, London, December 16, 1896.

tion, 11 rheumatism, 9 scurvy, 6 pleurisy (whether tuberculous is not stated), 2 pneumonia, 1 a mediastinal tumor, and 6 general dropsy resulting from (*a*) "heart disease" (character not stated), 2; (*b*) nephritis, 2; (*c*) chronic bronchitis, 1. In 17 of the cases no complication or etiologic factor was assigned to the condition, in 3 the inflammation was due to trauma, and in 12 the effusion was purulent. From these figures it would appear, therefore, that other factors beside rheumatism and tuberculosis play a very important rôle in the production of pericarditis although it is probable that at the present day scurvy, on account of its comparative rarity, as an etiologic entity may be almost entirely eliminated.

The case which I am about to report is in many particulars, I think, unique; I have been unable to find a record of one in any way resembling it.

Mrs. R., sixty years of age, never pregnant, first came under my care in March, 1898, for periodic attacks of bronchial asthma. She was a well-preserved, fairly well-nourished woman, of equable temperament, weighing in the neighborhood of 130 pounds. At about the age of forty a fibroid growth of the uterus had developed and during the succeeding six years had so increased in size that her abdomen appeared like that of a woman at term. Flooding was frequent during these years, but she refused operation. At about this period change of life occurred, the bloody flow gradually ceased, and shortly thereafter the growth began to decrease in size. At the date of my first examination it was about as large as a child's head, was of stony hardness, irregular in outline, and firmly adherent. Its presence had not inconvenienced her in the slightest degree during the previous ten years, with the possible exception, perhaps, that urination had been somewhat more frequent than under normal conditions. Her bowels were inclined to be loose but this tendency had existed since childhood.

There was no history of tuberculosis in her family. Her lungs and kidneys were perfectly sound. She had a mitral regurgitant murmur of slight degree which, I was told, had first been detected some ten years before I first saw her. She had never been subject to rheumatism or to gout and had not had the ordinary diseases of childhood. The first of the asthmatic attacks had occurred in November, 1897, without warning, and though somewhat infrequent during the subsequent five months they then became of weekly occurrence. As a rule the seizures were during the early morning hours, the patient suddenly awakening from sleep with a feeling of constriction in the chest. Dyspnea immediately became intense, both inspiration and expiration being accompanied by a loud whistling sound, while the chest heaved, the face became cyanotic, and the surface of the body was covered with a cold sweat. Both lungs during one of these paroxysms were filled with coarse bubbling and whistling râles. Upon the subsidence of an attack expectoration was profuse and thick, although unaccompanied by severe cough, and the patient was left in a condition of complete exhaustion.

These attacks usually lasted from ten minutes to an hour, and within twenty minutes, as a rule, from the time of their ending the lungs were again perfectly clear and not a râle was to be heard. I was always able to cut a paroxysm short by causing the patient to inhale a few drops of amyl nitrite, followed at an interval of a couple of minutes by chloroform to the point of fleeting anesthesia. The hypodermatic use of morphin even in small doses at this time invariably caused nausea and had no appreciable effect in shortening the paroxysm. From March 17 to November 19, 1898, a general tonic treatment was followed, which, until October 23d included the administration of 10 drops, three times a day, of a saturated solution of potassium iodid during periods of two weeks at a time, and the diet was carefully regulated. So-called cigarettes of niter paper were frequently burned in the room near the patient but were of doubtful value. On October 23d the administration of potassium iodid was discontinued as it apparently was not doing good, and the patient's stomach with difficulty retained it even in small amount.

At no time during the course of the year, either at the height of a paroxysm or during the intervening periods, did the patient suggest the presence of pain in the region of the heart and at no time was the area of cardiac dulness increased or any symptom present which indicated involvement of the organ. Though somewhat weak the heart action was regular and there was no accentuation of the pulmonary sound.

On November 19, 1898, an exceptionally severe asthmatic attack occurred, which yielded but slowly to the usual remedies. From that date until November 27th the patient felt particularly well and was in excellent spirits, on several occasions venturing out of the house and walking a mile or more. During the morning of the 27th a dyspneic paroxysm developed which lasted three hours and was the most violent I have ever seen. Both lungs were filled with all varieties of râles and the heart-action was tumultuous and irregular. Two attacks occurred on the 28th, though less severe in character. During the afternoon of that day I again carefully examined her chest but with exactly similar results as on former occasions between attacks. With the exception of the slight degree of valvular involvement the heart appeared to be in a perfectly normal condition. The apex-beat, though weak, was to be felt in the fifth intercostal space about one inch within the mammary line. There was no pain on pressure over the precordial region and the normal area of cardiac dulness was not increased. A few moist râles were present in both lungs posteriorly.

Attacks of dyspnea occurred at intervals during the following night. Uncontrollable nausea and vomiting developed during the morning of November 29th, and the former continued almost without

intermission during the patient's waking hours for five days and nights in spite of every effort to control it. Dyspneic paroxysms lasting, as a rule, about twenty minutes, occurred at hourly intervals until the afternoon of the 30th, when the patient had three hours of refreshing sleep. When I visited her at four o'clock my attention was at once arrested by a marked change in the character of the radial pulse. Small doses of strychnin had been administered hypodermatically at intervals since the preceding morning, and although the pulse had become steadier and its volume had increased under the influence of that drug, it was now marked by a distinct intermission at regular intervals. This intermission, I presently noted, was synchronous with the act of inspiration. In order to verify this fact I twice directed the patient to inspire as slowly and as deeply as possible, and in each instance the length of time of the pulse intermission was nearly as long as that consumed in inspiration. The effort to breathe deeply brought on another severe attack of dyspnea which lasted nearly four hours with only occasionally a few minutes' cessation. This attack differed materially in character from those of the previous day as well as from those of the morning of the same day. Then the lungs were full of râles and expiration was loud and wheezy; at this time the lungs were almost entirely clear of râles and the breathing was devoid of the characteristic asthmatic wheeze. The pressure of a stethoscope over the cardiac region caused the patient intense pain, but this pain entirely disappeared upon removal of the instrument. She had not been conscious in any way of the presence of this painful area until this examination was made. Curiously enough only once during the subsequent course of her illness did she complain of pain in the region of the heart except when pressure was made in this locality.

An immediate examination of the heart demonstrated that fluid had already collected in the pericardial sac. There was an entire absence of pericardial friction-sounds, such as ordinarily would be noted in connection with inflamed pericardia before the advent of effusion. The cardiac impulse was absent from the fifth interspace. The action of the heart was irregular and labored and the first and second sounds were muffled and indistinct. The mitral regurgitant murmur could not be distinguished over the precordia. The area of cardiac dulness was considerably increased, its lower margin being distinctly crescentic. Even slight percussion in this region caused the patient severe pain; the exact area of dulness could not be satisfactorily determined.

Cloths wrung out in ice-water were applied over the precordia, but as this procedure merely aggravated the patient's discomfort, and as the dyspnea was growing more marked I determined that withdrawal of the accumulation in the sac was imperative. Dr. Walter Mendelson, who kindly responded to my call for assistance, agreed with me as to the condition present and as to the necessity for immediate operation, and at 8 P.M. the procedure was carried out.

The precordial region was washed as thoroughly as existing conditions would permit with a 1-to-500 solution of mercuric bichlorid followed by alcohol. Then, after Dr. Mendelson had administered a few whiffs of chloroform, the patient being supported in a sitting position by pillows, I introduced a medium-sized aseptic needle attached to an old-style antitoxin-syringe into the pericardial sac at a point about one inch from the sternum in the fourth intercostal space. The partial withdrawal of the piston was followed after a moment by the appearance in the tube of about half an ounce of blood-stained serum. The needle then became clogged and was withdrawn. The removal of such a small amount of fluid did not relieve the dyspnea and I therefore introduced a much larger needle, this time through the fifth interspace, the same distance from the sternum, and another ounce of fluid was removed. The second needle was inserted a distance of about two and one-half inches and during the manipulation at one time it scraped the heart, resulting in a slight spasm of that organ and decided pain to the patient, who was not anesthetized.

Marked relief as a result of the operation did not ensue until the expiration of an hour, when, under the influence of strychnin and whisky, hypodermatically, the heart action became more regular and strong, the breathing became normal, and, an opium suppository having been administered, the patient slept quietly during an hour. An analysis of the urine the same evening showed it to be of a specific gravity of 1018, dark in color, of an acid reaction, containing one and one-half per cent. of urea, earthy phosphates in small amount, and bile pigment. It did not contain albumin or casts.

The following morning (December 1st) the patient's breathing was normal, but her heart was very weak and irregular, the radial pulse being almost imperceptible. The heart responded quickly to the hypodermatic use of strychnin, followed after an interval by whisky, and these remedies were continued at two-hour intervals during the day. On account of the continued nausea attempts were made to administer high enemata of warm peptonized milk and whisky, but the patient was totally unable to retain them. Every known therapeutic measure was adopted in turn to check the nausea, but without favorable result. Considerable pain in the region of the heart was complained of (the only time during the course of her illness), and late in the afternoon an alarming sinking spell occurred. From this she soon rallied, under hypodermatic stimulation, but remained very weak. But four ounces of urine was voided from the early morning of this day until the evening of the following one, although five loose bowel movements occurred during the interval.

On December 3d the heart action was very rapid, irregular, and feeble. Five minims of tincture of digitalis and fifteen minims of whisky were administered hypodermatically every two hours, and one-sixtieth of a grain of strychnin every four hours throughout the day. Two high enemata of liquid peptonoids and milk were retained. On December

4th there was marked improvement. One minim of dilute hydrocyanic acid in a tablespoonful of hot water every two hours finally checked the nausea, and the patient was able to retain teaspoonful doses of liquid peptonoids and small quantities of orange juice, the first nourishment taken by the mouth in five days. The heart action was stronger and more regular. Twelve ounces of urine was passed. Under the influence of an opium suppository four hours of sleep was obtained. Another sinking spell occurred at four o'clock on the morning of December 4th, and another at 6 A.M. on December 6th. Nausea was again very pronounced on the last-named date and the collapse was so complete that dissolution appeared to be imminent several times during the day. She finally revived under the use of suppositories containing digitalis and stychnin and the heart action became stronger.

On December 7th almost complete aphonia developed and persisted two days. A urinary analysis on this day differed but little from those made previously. From this date until December 12th the patient held her own fairly well, although she did not gain in strength. She readily assimilated certain of the prepared foods and developed quite a healthy appetite. On December 12th cystitis of a peculiarly marked type suddenly made its appearance and persisted nearly three weeks, or until January 1st, in spite of every effort to control it. She had always voided urine naturally and a catheter had never been used. Urinalysis resulted as follows: Color, dark reddish; specific gravity, 1021; reaction, acid; solids, 48.93 grams to the liter; quantity in twenty-four hours, 28 ounces; urea, 1 per cent.; albumin, a slight trace; sugar, absent; indican, no reaction; bile pigment, present; casts, moderately numerous, hyalin only; epithelium, from bladder, and, possibly some from the kidney; pus, abundant; blood, an occasional corpuscle; bacteria, abundant. The diet was restricted to milk, and urotropin, first in 7½-grain-doses every three hours and later in 15-grain doses every four hours was administered, and the bladder was washed out at regular intervals. Warm water, followed by solutions of boric acid, permanganate of potash, and nitrate of silver were tried in turn, with but little effect in favorably influencing the inflammation. The urotropin, especially in the larger doses, undoubtedly cleared the urine markedly, but for fear of a recurrence of the nausea its use was finally discontinued. The sensitiveness of the bladder was so acute that it was necessary to introduce a two-per-cent. solution of cocain into the viscus previous to each irrigation. Except over the region of the bladder there was no abdominal tenderness present, and I doubt if the pelvic growth, to which I have referred, exerted any influence in the production of the cystitis. About one ounce of urine was voided every hour during this period, and it was possible to relieve the patient from pain only by the free use of suppositories containing opium and hyoscyamus.

On December 24th bronchitis developed, but after a few days it yielded to carbonate of creasote in 5-minim doses every four hours. On December 30th the pain in the bladder was so intense that the patient had to be kept under the influence of morphin almost continuously. The following day (January 1, 1899) I cocainized the bladder and irrigated it with a solution of mercurol, a new preparation forwarded to me through the courtesy of Parke, Davis & Company of Detroit. This preparation, I am told, is a true chemical compound of nucleinic acid with mercury, containing ten per cent. of the latter drug. Its properties in the treatment of inflammatory conditions accompanied by pus formation were first brought to my attention by Dr. Robert Winthrop Gillman of Detroit, and although I was somewhat sceptical as to its ability to bring about the favorable results claimed by him, it greatly exceeded my expectations As a result of the irrigation the patient experienced relief almost immediately. The irrigations with mercurol were repeated at intervals on January 2d and 3d, and by the evening of the 4th no semblance of pain was referable to the bladder, the urine was of a specific gravity of 1018, there was no pus present, and but a slight trace of albumin.

On January 5th a serious sinking spell occurred at six o'clock in the morning, and the patient did not react except under the influence of amyl nitrite, digitalis, and whisky. The breathing was short and labored, the face became cyanotic, the pulse was thready and irregular, and there was pronounced pain on pressure over the heart. Careful percussion failed to reveal an increased area of cardiac dulness, the first and second sounds were clear, not muffled, and the apex beat was practically normal. As the patient was voiding but twelve to sixteen ounces of urine during each twenty-four hours at this time infusion of digitalis was substituted for the tincture, with beneficial results, the quantity of urine increasing to about three pints daily. An analysis showed it to be free from albumin and casts.

Uncontrollable nausea set in on January 6th and continued until the evening of the following day. Two sinking spells occurred on January 9th but were successfully combated by the application of hot compresses over the cardiac region. In the evening of this day a marked friction-sound, synchronous with inspiration and expiration, was heard over the precordia just within the nipple line. Flatulency was complained of on January 12th. The bowels were greatly distended, but the condition was relieved by enemata of hot water containing a few drops of oil of peppermint. An attack of nausea occurred during the morning of January 14th, but was soon controlled, and the patient was in better spirits, and apparently was in better condition physically than at any time since the beginning of her illness. On January 16th an attack of nausea occurred at about noon, but was controlled. At 3 P.M. the patient complained of intense pain in the abdomen, especially at a point in the median line just below the umbilicus. Her breathing at this time was quiet, but her heart action since early morning had been weak and irregular in spite of considerable stimulation. She did not complain of pain in the region

of the heart. At 5.30, while in the act of speaking to her nurses, her head suddenly fell back on the pillow and she died instantly. Autopsy, much to my regret, was refused.

The features of interest in this case to which I would particularly call attention are: first, the age of the patient; second, the suddenness of the onset of the pericardial inflammation; third, the absence of an etiologic factor, such as trauma, tuberculosis, or rheumatism, in its production; fourth, the absence of pain in the region of the heart, except on one occasion and when pressure was made in this locality, during the entire course of the illness; and fifth, the fact that there was no recurrence of the typical asthmatic attacks after the development of the pericarditis.

From a superficial consideration of the case it would be natural to arrive at the conclusion that from the beginning the dyspneic paroxysms were in reality a manifestation of a pathologic condition of the heart or pericardium, or more properly, were due to a latent pericarditis which finally became acute. Allowing the supposition that in a majority of cases of pericarditis the inflammation is accompanied by effusion, in support of the theory it may be said that in the greater number of the cases tabulated by West the pericarditis had been of long duration, in some instances several months, before the necessity for paracentesis became manifest. In the case of one subject the effusion had been present more than four years. In but twenty-five cases was the duration short, and the attack, therefore, more or less acute. On the other hand, while certain authorities have said that it is probable that no one of the serious diseases is so frequently overlooked as pericarditis, and that the evidences found on post-mortem examination are the first intimation to the physician that the disease existed in his patient, it is to be remembered that in this instance careful examinations of the chest were made at frequent intervals and that symptoms of such a condition were wholly absent. At no time previous to the onset of the acute attack did the patient experience pain in the region of the heart; pericardial friction sounds were not present; and, as regards the possibility of the effusion having been of long standing, there was no prominence of the intercostal spaces of the left chest; the apex-beat was in its normal position; the heart-sounds were clear and distinct; the action of the organ was in no way hampered; and finally, the normal area of cardiac dulness was not increased. Coupled with these facts is the one that the dyspneic paroxysms previous to the discovery of the pericardial involvement were so distinctly typical of bronchial asthma, and were so markedly different in character from those which occurred later, that, to my mind, the heart cannot be regarded as having been a factor in their production. Again, it has been claimed that the occurrence of attacks of bronchial asthma are due to a neurosis of the vagus, and facts have been cited to substantiate the theory that the spasms in many instances are of reflex origin. One German clinician of wide experience, however, asserts that it is extremely doubtful if asthma of a purely bronchial type can originate from this cause.

The suddenness of onset of the attack and of the appearance of the effusion I am at a loss to account for, especially in the absence of a satisfactory hypothesis as to the origin of the inflammation. The dyspneic attacks of the morning of the day upon which the pericarditis was discovered did not differ from those from which the patient had suffered during the preceding year, while, as has been said, the subsequent attacks were entirely dissimilar.

The long-continued nausea, in the absence of a better explanation, would appear to have been due to reflex irritation along the course of the pneumogastric, or through the sympathetic, and the attack of aphonia to inflammation of or pressure on the recurrent laryngeal. The fact that the pelvic growth had not given rise to reflex symptoms during so many years would argue against attributing the nausea to this cause. Bright's disease, as a factor in the causation either of the asthma or the nausea, can also be eliminated.

The great relief following the withdrawal of so small an amount of fluid from the pericardial sac is not without precedent. A number of instances of like character have been recorded. In this connection it is interesting to note the surprising distensibility of the sac in the presence of effusion, as reported by several observers. Thus Kidd[1] withdrew thirty-three ounces at two tappings, closely following each other, and West, from another patient suffering from purulent pericarditis, removed two quarts.

I have no explanation to offer for the occurrence of the intense abdominal pain just before death. It did not appear to be referable in any way to the heart, neoplasm, or bladder. The question as to whether it was due to the passage of a stone, and whether an underlying uric-acid diathesis was the factor in the production of the pericarditis and the cystitis is an interesting one. The history of the patient, however, would argue against this supposition.

The intermittent pulse, or *pulsus paradoxus*, developed by this patient, although claimed to be practically an always-present symptom of pericarditis with effusion, is said by West to be an exceedingly

[1] *Lancet*, February 2, 1895.

rare phenomenon. "Pulses which vary with respiration are not at all uncommon in the minor degrees, especially in cases of heart disease; but the regularity is then nearly always cardiac in origin, that is to say, the irregularity of pulse is due to irregularity of the heart's action. The true *pulsus paradoxus* is essentially different. Here the heart continues to beat regularly, although the pulse intermits, and this intermission occurs during each inspiration, lasting as long as inspiration lasts." It perhaps will be remembered that at the time this character of pulse was noted in this patient the heart action was rapid and very irregular. A stethoscope applied over the heart at the same time that a finger compressed the radial pulse, however, left no room for doubt as to the stoppage of the latter during each inspiration independently of the regularity of the cardiac pulsation.

SOME STATISTICS UPON SERO-THERAPY IN TUBERCULOSIS.[1]

By J. EDWARD STUBBERT, M.D.,
of Liberty, N. Y.

As a result of some years of investigation by eminent men, such as Koch, Maragliano, de Schweinitz, Trudeau, and many others, there seems to be among the profession a growing belief that there will be found a specific or immunizing agency, either in the bodies of the tubercle bacilli or in the serum of animals which by repeated injections of virulent or attenuated cultures of the same have been rendered immune. Which one of these beliefs, if either, will prove correct is still to be determined. Unfortunately many failures have been recorded from the use of the crude tuberculin, old and new, of Koch, Kleb's modification, and other extracts of the bacilli. There has been created a rebound of feeling amounting to distrust of all tuberculins and sera which makes the profession exceedingly cautious in accepting data put forth as evidence of the value of serotherapy in tuberculosis.

History.—Among those inclined toward a specific mode of treatment the trend of opinion seems to be in the direction of antitubercle serum as derived from animals rendered partially immune by repeated injections of attenuated cultures of the tubercle bacilli. The history of antitubercle serum may be said to date back as far as 1890, although some unpublished work was done before that time. In that year Bernheim and Bertin both attempted the transfusion of goat's blood for tuberculosis. The next year Coupard and St. Hilaire used dog-serum in the form of intertracheal injections, and Haricourt treated human subjects with dog blood-serum. In 1894 de Schweinitz succeeded in producing partial immunization of guinea-pigs; Babes in 1895 made some experiments with dog serum; Maragliano has for the past three years treated tuberculosis with asses'-serum. Behring asserts that he has produced an antitubercle serum capable of arresting tuberculosis in small animals; Paquin has been engaged in experimentation along this line since 1894, and numerous excerpts have been published by different practitioners who have claimed excellent results from the use of this serum.

Theory of Action and Method of Preparation.—While tuberculin, antiphthisin, tuberculosidin, and other extracts composed of the toxin of the bacilli are supposed to act indirectly upon the germ when injected into man the antitubercle serum such as prepared by de Schweinitz and Maragliano is supposed, when introduced into the human body, to have an antitoxic effect. In manufacturing antitubercle serum, dogs, goats, asses, horses, and cows have all been used, but the horse seems to be the favorite animal in the hands of most experimenters. The methods of preparation of antitubercle serum employed by each of the aforesaid scientists differ.

Perhaps one fault is that we treat too much the effect rather than the cause of this disease. Acknowledging the claim that the injections of the serum of an animal rendered immune will reinforce Nature's own forces which are striving to correct a diathesis inherited, a soil already prepared for the nourishment of the bacilli, we find ourselves looking toward immunizing our patient; therefore the use of the antitubercle sera of Maragliano, de Schweinitz, and others. The tubercle bacilli are inhaled in all of our large cities by the majority of their populations, and we find that only five to eight per cent. contract the disease; therefore there are in Nature forces which, if properly reinforced, may battle successfully with these germs even if the odds are against them.

In 1894 de Schweinitz began treating animals for the purpose of providing possible immunity or resistance to tuberculosis by attenuated cultures. He says: "The production of this *partial immunity or artificial resistance* by attenuated cultures, already in 1894 suggested the advisability of this same method for the production of a serum that would have some effect in curing tuberculosis. Two cows and one heifer were first selected and treated with tuberculin or injected with the liquid culture-media in toto, including the germs just as obtained from the incubation without any other treatment. The first few injections caused slight reaction and occasionally local edema or abscess was produced; subsequently this decreased. Guinea-pigs were then injected with the

[1] Read at the Fifteenth Annual Meeting of the American Climatological Association, Bethlehem, N. H., September 1, 1898.

serum taken from these animals and subsequently were inoculated with virulent cultures. The checks died within four or five weeks." He says further: "Without giving the details of the experiment *we may say that the serum from the cows treated with tuberculin would cause, in pigs, slight resistance to the disease;* the serum of those treated with attenuated bacilli produced more resistance on the part of the animals, but not sufficient as compared with the quantity of the culture injected to make the use of cow-serum practical. The cow-serum, although sterile, frequently produced abscesses in guinea-pigs. While these experiments were in progress two horses were pressed into service and were injected with attenuated culture fluid and bacilli; after a time the abscess formation almost ceased." The effect of the serum he also tried in preventing the rise in temperature and in counteracting a fatal dose of tuberculin in tuberculous guinea pigs. There is one encouraging point to be noted in this connection—that these experiments have been made upon guinea-pigs which are well known to be very rapidly affected by tuberculosis. By noting that the immunizing is a gradual process it would seem that the resisting powers ought to be proportionately better in the human subject. De Schweinitz finally says: "*The experimental results obtained lead undoubtedly to the conclusion that the treatment with antitoxic serum is still in the experimental stage and should as yet be used only in sanatoriums and under the best conditions. We are on the road to success in the treatment of this disease, and nearer our goal than ever before.*"

Statistics at Large.—The favorable results reported so frequently from the use of different antitubercle sera by numerous physicians lead members of the profession to be suspicious, fearing that there might be a commercial side to the records presented, especially when our desks are loaded down with short résumés of five or six cases treated with one particular serum or another by men who have not been known among their professional brethren before the appearance of these reports. This mistrust is especially engendered when these same reports are published at the expense of and offered to us by the commercial houses controlling the output of the different sera. Still there have been among the many reported cures a sufficient number that seemed credible, and the names of a few of the investigators and reporters have stood so high in the profession as to make it obligatory upon us to investigate constantly and carefully along the line of serotherapy in the treatment of tuberculosis. Maragliano claims good results and other men of note have reported a few favorable cases from its use.

While we should strongly urge the need of still adhering to the climatic, hygienic, and dietetic treatment that long experience has established it would appear to be our duty to constantly search and investigate, by the records of accumulative cases, for further evidence as to the efficiency of serum treatment. Dr. de Schweinitz, Director of the Biochemic Laboratory of the Bureau of Industry, Washington, D. C., some two years ago proposed placing in the writer's hands, on non-commercial, purely scientific grounds, an antitubercle serum manufactured by the Government, to be used for purposes of experimentation. Having been impressed by the sincerity of this proposition the writer immediately began to treat patients under his care at the Loomis Sanitarium at Liberty, N. Y., and in private practice for the purpose of ascertaining if possible whether they could not only be cured but immunized by this treatment; and in following this line of investigation he has been led to use in a few cases incidentally, in addition to the de Schweinitz serum, Paquin's antitubercle serum, Fisch's serum, Hirschfelder's oxytuberculin, and Pasteur's antistreptococcic serum.

Remarks. — Dr. E. G. Janeway of New York tells me he has known but one favorable result from the use of antitubercle serum, and that was in a patient of Dr. Trudeau. Dr. S. S. Jones of New York City has used this serum in three cases, two in the incipient stage, and one far advanced. His observations in these cases lead him to believe that this serum is possessed of tonic qualities but no specific virtues. Dr. R. M. Meade of Brooklyn has used antitubercle serum in four cases, with very gratifying results. The writer has treated two patients living in New York City, one of whom did remarkably well, while in the other the results were unfavorable; the first case was in the incipient stage, the other one in the far-advanced stage.

The serum of Dr. Fisch was tried in six cases at the Sanitarium, but as every one of the patients showed bad results they were transferred to other serum or treatment. Some of the bad results encountered from the use of this serum were eruptions and severe reactions. Paul Paquin's serum was also used in about eight cases, but as the percentages of good results were lower than from the use of other serum its use was finally abandoned. Very severe reactions were encountered from the use of this serum. In one case the bacilli disappeared for a short time but subsequently reappeared. It is but just to these gentlemen to state that other observers have reported favorable results from the use of their sera.

Class in Which Indicated.—The use of antitubercle

serum would seem to be indicated only in incipient cases, and in those presenting a pure culture or simple infection. This of course refers to those patients whom we hope to be able to cure. In the writer's experience it has seemed in a few advanced cases to temporarily retard the progress of the disease; it reduced temperature and increased materially the strength of the patients. I remember one patient especially whose physical signs were as fol lows: Dulness over entire right lung; cracked-pot resonance to second interspace; large mucous râles right side to nipple; gurgles and subcrepitant râles second interspace; crepitant and creaking râles right side posteriorly; amphoric respiration over site of cavity; increased vocal resonance and bronchial respiration apex to nipple. This patient had become so ill as to be confined to one of the infirmary beds of the Sanitarium, and was unable to walk even across the room. Every possible effort had been made to ameliorate her condition but without success. To please her, against my judgment, simply as a placebo, I directed that she be given 1 c.c. of de Schweinitz's serum on alternate days. Within a short time her appetite returned, her temperature was slightly reduced, she was able to move around the room, and finally, to my astonishment, I met her one day walking around the Sanitarium grounds. The effect upon this patient was of course only temporary, and after a few months she died. Generally speaking, the use of antitubercle serum would seem to be *contraindicated* in the third stage of pulmonary tuberculosis, cases of marked softening or excavation, those of marked hereditary taint, in patients presenting a very rapid action with relative feebleness of arterial pressure, and in those in whom corpulence, vital capacity, and conformation of the chest are much below the normal standard; also, in cases of marked mixed infection. Maragliano does not, I believe, agree with this statement, claiming that the use of antitubercle serum is indicated in all cases and in all stages.

Accidents in Administration.—There seems to be but little if any danger attendant upon the administration of serum if the proper precautions in the way of antisepsis are observed in its use. Urticaria, erythema, and other forms of eruptions, sometimes swellings, in different joints, especially in patients presenting a rheumatic diathesis, painful swellings at the point of injection, stiffness, pain, enlargement of the axillary glands, and myalgia are met with in a small percentage of cases. These symptoms, however, are not dangerous, only annoying, and even in the small percentage of patients who present them are seldom repeated during subsequent treatment. The only really alarming symptom that has ever been observed by the writer has been sudden attacks of syncope lasting from one to two minutes. Some claim this is due to the serum being passed directly into a small vein, while others say it is caused by too frequent injections at a given point.

Clinical Symptoms in Successful Cases.—The advantages of serum treatment are: first, it does not tax the functions of digestion or produce gastritis, diarrhea, or loss of appetite; second, in subjects from whom the bacilli have disappeared, they have been lost while sputa were still present, whereas in creosote cases the last specimens of sputa contained bacilli; third, up to the present time *no relapses have occurred* among our patients apparently cured by serum treatment; relapses are not unfrequently met with in creosote cases. Some of our serum patients after leaving the Sanitarium have been subjected to rather serious climatic and hygienic tests without mishap.

The writer has lately examined between fifteen and twenty patients treated with serum, and has not found one who had redeveloped the disease; on the contrary, all have been enabled to remain in their homes and at their work. All these patients have been away from the Sanitarium for periods varying from six months to one year and a half. *There would seem to be established a certain immunity in subjects apparently cured by serum, but how lasting this may be is still to be determined.*

Length of Time of Administration.—The average length of time that antitubercle serum can be given advantageously in cases *improved* or *arrested*, but not cured, would seem to be about six or seven months, and thereafter appears not only non-utile but gives rise to unpleasant symptoms. In patients apparently *cured* under the administration of serum it has been my custom to continue its use for two or three months after the disappearance of tubercle bacilli. In these cases no unfavorable results have been noted from its long use.

Antistreptococcic Serum.—While, as seen above, the results from the use of antitubercle serum have been somewhat encouraging in cases showing a pure culture, the most alarming symptoms and trying complications with which the physician meets in tuberculosis are due not to the tubercle bacilli but to the cocci of mixed infection. The most virulent one of these seems to be the streptococcus, and the profession is watching with great interest the result of the use of Marmorek's antistreptococcic serum in the hope that in tuberculosis with mixed infection (the most common variety) the disease may be reduced to one of simple tuberculous infection that will more readily yield to antitubercle serum. This hope is a legitimate one in view of the results reported from

its use in erysipelas, active abscesses, pelvic inflammation, otitis media, and acute and chronic suppurative processes generally. Paquin claims to have obtained good results in almost all cases of mixed infection from the administration of antistreptococcic and antitubercle serum on alternate days. Knopf, in the *Medical Record* of February 13, 1897, recommends its use in early cases, remarking that generally good results are not to be looked for when the temperature is higher than 101° F. Weaver, in the *Journal of the American Medical Association*, reports a case in which one dose of this serum reduced the patient's temperature from 105° F. to nearly normal, but he fails to state whether it remained so. Cox, in the *Journal of the American Medical Association* for September 11, 1897, refers to three successful cases of Weaver, and beyond that deals in generalities and hopes.

The writer has been led to employ Pasteur's antistreptococcic serum in six cases of mixed infection (selecting, of course, only such cases as showed streptococci), believing that if the secondary infection could be neutralized a clear field would be left for the supposed action of the antitubercle serum. In the first case only one injection was employed; expectoration ceased immediately for a number of days, and then returned in diminished quantity; on examination the streptococci were found to be far less numerous. The next patient had suffered from chronic bronchitis for three or four years and developed tuberculosis a short time before entering the Sanitarium, about sixteen months ago. Tubercle bacilli disappeared under treatment but bronchitis remained. The sputa were mucopurulent in character and contained streptococci. One injection of the antistreptococcic serum was given, after which cough and expectoration increased materially. After a few weeks the patient began to improve and expectoration decreased somewhat in quantity, and became very markedly less purulent in character. This patient is now living in New York, and after five months the streptococci have reappeared. The next patient had a dry cavity at one apex. She had done very well at the Sanitarium. She was given four injections of the antistreptococcic serum, after which the streptococci disappeared. This patient is still an inmate of the Sanitarium, and her sputum still contains tubercle bacilli.

The next case was that of a young lady whom I have treated, first as a private patient then as an inmate of the Sanitarium for the past fifteen months. Tubercle bacilli disappeared from her sputum, the physical signs cleared up, and she was about to return home cured of tuberculosis. However, she also had a history of chronic bronchitis, but with scanty expectoration. About the time she was about to be discharged from the Sanitarium numerous and long chains of streptococci were discovered in her sputa, and she was immediately given an injection of 10 c.c. of antistreptococcic serum, and two days later a second injection of 10 c.c. After the first injection a slight increase of expectoration was observed, but a few days after the second injection no streptococci could be found nor could be for four months, at the end of which time they reappeared. In a fifth case three injections were given, but without any effect. The sixth patient was given two injections at intervals of ten days. After the first injection the streptococci were greatly reduced, and after the second injection they had disappeared entirely. This patient is still an inmate of the Sanitarium and at the end of six weeks the streptococci had not reappeared.

I cannot agree with the statement that it is advisable to administer this serum at such short intervals as forty-eight hours, as in the only two cases in which I have done so there have been marked systemic disturbances. It is certainly more comfortable to the patient, and the results have appeared to be equally good when from one to three weeks have been allowed to elapse between the injections. Generally, the sreptococci decrease very greatly or disappear entirely after the second administration of the serum, and in exceptional cases, one injection may be all that is necessary. The largest number of injections given by the writer to any one patient suffering from pulmonary infection has been four.

The results recorded above have led the writer to adopt the plan of using this serum regularly in conjunction with the antitubercle serum, but less often than recommended by some others. The question of the efficacy of this serum would still seem to be *sub judice*, but in all sanitariums and in private practice among specialists in this disease, where a sufficient number of cases of this mixed infection can be found, a careful investigation carried on during the coming year would be interesting.

A summary of the results of eighty-two cases of all classes treated at the Loomis Sanitarium is given below. These cases have been divided for convenience into three classes—incipient stage (slight localized involvement of lung, with little or no constitutional disturbances); moderately advanced (more general consolidation of lung, with constitutional disturbances and beginning of softening or single cavity), and far advanced (softening and excavation, with marked constitutional disturbances).

Number of patients treated, 82. Expectoration decreased in 82 per cent.; appetite improved in 81 per cent.; weight gained in 78 per cent.; physical

signs improved in 78 per cent.; temperature decreased in 49 per cent.; bacilli disappeared in 13 per cent.; apparent immunity established in 21 per cent.; bacilli decreased in 35 per cent.; cough decreased in 79 per cent.; generally improved 78 per cent.

NOTE.—The percentage of good results from the use of antitubercle serum, as regards temperature and tubercle bacilli, are less during the summer than winter months, and it is an interesting fact that this remark can be applied to all lines of treatment. Incidentally, I wish to state that I have been very much surprised during my two-winters' experience at Liberty to find that in patients in whom the average power of resistance was not very low high winds and exercise in unprotected places has not been detrimental. On the contrary, patients have improved far more rapidly than during the comparatively mild weather.

The treatment of cases of laryngeal tuberculosis has received special attention at the Sanitarium, and the results compare most favorably with reports from other health-resorts. The results in these cases have been as follows: Patients in whom the ulceration healed, 50 per cent.; in whom there was no ulceration, but in whom the disease was arrested, 46 per cent. In these laryngeal cases serum has been used in seven, and although no immediate results were apparent in the larynx it is possible that the serum contributed in some degree to the favorable percentages.

I wish to place myself distinctly on record as not being as yet a thorough convert to sero-therapy in the treatment of tuberculosis. I am simply an investigator of this subject. I believe that we are investigating along the right line; that the results of serum treatment are as a whole more satisfactory than treatment by any one drug, but as yet we have found no specific for this dread disease.

OPERATIVE GYNECOLOGY ON THE INSANE.

BY W. P. MANTON, M.D.,
OF DETROIT, MICH.;
PROFESSOR OF CLINICAL GYNECOLOGY AND ADJUNCT PROFESSOR OF OBSTETRICS IN THE DETROIT COLLEGE OF MEDICINE;
GYNECOLOGIST TO THE EASTERN AND NORTHERN MICHIGAN ASYLUMS FOR THE INSANE;
GYNECOLOGIST TO HARPER HOSPITAL.

THE forthcoming biennial report of the Superintendent of the Eastern Michigan Asylum, Dr. E. A. Christian, will contain a short summary of the gynecological operations which I have performed at this institution during the two years, July, 1896, to July, 1898. Twenty-eight operations, often several on the same patient, were performed on seventeen women, as follows: Vaginal hysterectomy, 3; abdominal hysterectomy, 1; celiotomy for intraligamentous cyst, 1; ventral fixation, 4; curettage and divulsion, 6; trachelorrhaphy, 4; perineorrhaphy, 3; anterior colporrhaphy, 1; posterior colporrhaphy, 1; occlusion of vagina, 1; removal of uterine polypus and submucous fibroids, 1; removal of hemorrhoids, 2. Subsequent to operation 4 patients were cured of mental disorder (23.52 per cent.), 3 improved mentally (17.64 per cent.), and 10 remained unimproved mentally. There was no mortality from operation. Of the 4 patients who recovered 1 had melancholia, the duration of the mental attack being unknown; 1 had melancholia which had existed nine months; 1 had acute mania of ten-weeks' duration, and 1 had had acute mania for one year and seven months.

The recovery of mental health in more than thirty-three per cent. of the cases treated is certainly very encouraging, and could this result be attributed solely to operative interference, the popular, and to some extent professional, idea that insanity in the female is largely due to disease of the pelvic organs, and consequently curable by the removal of this disorder, would be conclusively demonstrated. But, while my large experience in gynecology among the insane leads me to ascribe all due credit to operative measures in the treatment of this class of the sick, I have repeatedly asserted as my opinion that, while surgery for the cure of local disease in the insane is an important means to an end, other factors must also be included as fostering the ultimate result. Thus the quiet and methodical habits of asylum life, food, internal medication, and the regulation of bodily functions must all be looked upon as contributing to the general upbuilding of the patient's physical health and of equal importance in the re-establishing of mental integrity. The day, which never existed in this institution, when normal structures were removed for the cure of insanity is happily long since passed, its memory alone remaining as an ugly stain upon the fair page of enlightened, progressive surgery.

What I do believe, however, and have maintained for more than a decade, is that the insane woman suffering from pelvic disease is as much entitled to relief from her somatic ailment at the hands of the State or individual as she is to housing, the clothes she wears, or the food she eats. Morally or legally there exists no right to confine these patients within asylum walls and permit them to drag out a wretched existence hampered not only by the "blot on the brain," but also by physical suffering which can be relieved. If the combined results of asylum treatment and surgical procedures succeed in bringing about a cure of the mental malady there is great rea-

Form of Insanity.	Duration.	Condition Requiring Operation.	Nature of Operation.	Results of Operation.	Subsequent Course of Mental Disease.	Remarks.
1. Melancholia.	1 year 8 months.	Chronic metritis.	Vaginal hysterectomy.	Cure of local disorder.	No change; patient committed suicide 9 months later.	
2. Dementia, chronic.	20 years.	Uterine polypus, submucous fibroids.	Removal and enucleation.	Cure of local disorder.	No change mentally.	
3. Dementia monomania.	10 years.	Extreme recto-cystocele.	Occlusion of vagina.	Temporary relief.	No change mentally.	
4. Dementia, epileptic.	13 years.	Retrodisplacement of uterus.	Ventral fixation.	Cure of local disorder.	No change mentally.	
5. Periodic insanity.	13 years.	Procidentia, complete.	Vaginal hysterectomy, perineorrhaphy.	Cure of local disorder.	Improved mentally.	Now with friends.
6. Periodic insanity.	28 years.	Laceration of cervix, endometritis.	Divulsion, curettage, trachelorrhaphy.	Cure of local disorder.	Improved mentally.	Now with friends.
7. Melancholia.	(?) years.	Retrodisplacement of uterus, prolapse of one ovary.	Ventral fixation.	Cure of local disorder.	Recovered mentally.	
8. Paranoia.	6 years.	Retrodisplacement of uterus.	Ventral fixation.	Cure of local disorder.	Improved mentally.	Great physical improvement.
9. Melancholia.	9 months.	Laceration of cervix and perineum.	Divulsion, curettage, trachelorrhaphy, perineorrhaphy.	Cure of local disorder.	Recovered mentally.	
10. Dementia monomania.	5 years.	Laceration of cervix, endometritis.	Divulsion, curettage, trachelorrhaphy.	Cure of local disorder.	No change mentally.	More comfortable, neater.
11. Dementia, chronic.	18 years.	Procidentia, complete.	Vaginal hysterectomy.	Cure of local disorder.	No change mentally.	More comfortable.
12. Dementia monomania.	10 years.	Carcinoma uteri.	Abdominal hysterectomy.	Recurrence of disease in pelvic tissues.	No change mentally.	
13. Mania, acute.	10 weeks.	Laceration of cervix, endometritis.	Divulsion, curettage, trachelorrhaphy.	Cure of local disorder.	Recovered mentally.	
14. Periodic insanity.	9 years.	Intraligamentous cyst.	Abdominal section, removal of cyst, appendages, ventral fixation.	Cure of local disorder.	No change mentally.	
15. Dementia, chronic.	19 years.	Endometritis, hemorrhoids.	Divulsion, curettage, removal of hemorrhoids.	Cure of local disorder.	No change mentally.	Not as troublesome at menstrual periods.
16. Melancholia, chronic.	19 years.	Procidentia, partial.	Anterior, posterior colporrhaphy, perineorrhaphy.	Cure of local disorder.	No change mentally.	Not as complaining.
17. Mania, acute.	1 year 7 months.	Endometritis, hemorrhoids.	Divulsion, curettage, removal of hemorrhoids.	Cure of local disorder.	Recovered mentally.	

son for congratulation; but if, in spite of all, the disordered mind still remains disordered there is satisfaction in the knowledge that in bringing bodily relief to one of these unfortunates we have proffered the "cup of cold water," and in this have our reward.

The accompanying tables show the form of insanity, its duration, the local disorder, nature of the operation undertaken, and the results in the seventeen women upon whom operations were performed.

CLINICAL LECTURE.

TREATMENT OF FRACTURE OF THE PATELLA.

BY LEWIS A. STIMSON, M.D.,
OF NEW YORK;
PROFESSOR OF SURGERY IN THE CORNELL UNIVERSITY MEDICAL COLLEGE.

THE patient brought before you to-day is a man thirty-five years of age, who yesterday, while stooping and forcibly lifting with his hips and knees flexed, felt something give way at his right knee. He did not fall, but found himself unable to use the limb because of lack of power. On examination we find across the front of the right knee-cap a transverse gap, into which the finger can be slightly sunk; a gap which marks the separation between the upper and lower halves into which the patella has been broken. The line of fracture is transverse, and about at the middle of the bone. By pressing with the end of the finger on either side of the knee just beyond the border of the patella and in line with the fracture, the sense of diminished resistance in the capsule of the joint can be felt, an indication that the capsule is torn transversely at this point, the rent in the capsule extending on each side in line with the line of fracture. There is slight distention of the joint, due doubtless to blood and to increased synovia. The separation when the knee is fully extended and the patient making no effort, is rather more than half an inch.

The mode of production of the fracture is, as the history shows, indirect; that is, the bone has been broken by a strain exerted upon it on the one side through the ligamentum patellæ, on the other through the tendon of the quadriceps. This is the usual method of production of this fracture, and fractures thus produced present difficulties in treatment which are not usually found in fractures due to direct violence, those in which the blow has been received upon the front of the patella. The reason of this difference is that in fractures by direct violence, unless the blow is accompanied or followed by contraction of the attached muscle, the fragments are but slightly separated, and are held together by the fibro-periosteal layer which so thickly covers the front of the bone, while, on the other hand, in fractures by indirect violence this layer is completely ruptured transversely, and as its rupture habitually takes place, in part, at least, at a different level from that of the break in the bone, a portion of it remains as a fringe, which drops in between the fragments. This fringe may also be associated with long, shreddy strips of fascia torn loose at a lower level, remaining attached to the upper fragment and lodging between the two parts of the bone. Such strips of fascia and such a fringe are obstacles to close approximation of the fragments, and may prevent not only bony, but even close fibrous union between them.

If now I take the upper and the lower fragments between the thumb and finger of either hand, I can press them together, and can even get, on moving them sideways when thus held together, a little crepitus. This is not a proof that a fringe is not present in the case.

Diagnosis having been made, the question of treatment is next in order, and the first question to be determined is whether the treatment shall be by operative or non-operative methods. That question is one in which other things are to be considered than the probability, or, I might say certainty, of obtaining only fibrous union if non-operative methods are used; and, on the other hand, the probability that by operative methods bony union can be obtained. Close fibrous union, or even union by a bond half an inch long, is entirely compatible with good functional use of the limb, and such union can probably, as I have said, be obtained by non-operative methods. The chance of a failure of union, or of a union of a character that will lead to more or less disability, is not a great one. On the other hand, operative interference exposes to the risk of infection of the wound and subsequently of the joint, and of serious complications, including even amputation of the limb or the death of the patient. Under operations properly performed and with all the precautions which go to make up the proper performance of a surgical procedure, such a risk is very slight, but in my judgment an operation should not be undertaken except by those who are in the habit of operating, and who can have the aid of trained assistants. Although I have long habitually used operative methods in the treatment of this class of cases in hospital, and although my own experience, like that of many others, is free from disastrous results, yet I have never taught that operative treatment should be routine treatment, but that, on the contrary, the general practitioner, and even those who occasionally practise surgery, were not only justified in resorting to non-operative treatment of fracture of the patella, but even that it was their duty so to do, the reason being that the superiority of the results obtained by operative treatment over those of non-operative methods was not sufficient to warrant the incurring of risks which would accompany operation at the hands of those who could not bring to it the experience and the trained assistants I have spoken of.

The method which I habitually employ is one which I deem peculiarly safe, because the operation can be done without once touching the divided tissue with the fingers, and it is through the fingers that the principal risk of infection comes. The reasons for resorting to operation when the operation can be surrounded with all these precautions are: That the exposure of the seat of fracture enables the surgeon to remove those causes of failure of union which exist in a certain, but I think not large,

proportion of cases. Against those causes of failure non-operative methods are powerless. I refer especially to the long strips of fascia above mentioned, and to long, broad fringes of the fibroperiosteum.

Furthermore, when the joint is largely distended by blood and synovia, that distention in itself opposes and may prevent close approximation of the fragments. An open incision, by allowing the contents of the joint to be evacuated, removes this obstacle.

I shall say nothing now about non-operative methods, but speak only and briefly of the method of operation which will be done in your presence. The object of operation is to empty the joint, force the fragments together, and keep them together until repair is effected. The influence of the quadriceps in separating the fragments is not great. If the patient is recumbent, with the foot raised a few inches above the bed so that the knee is straight and the hip slightly flexed, the voluntary contraction of the quadriceps cannot separate the fragments more than one-quarter, or perhaps half an inch. In the absence of such contraction of the quadriceps the fragments remain quite close together and can easily be held together. For that reason, and also because of the more prolonged manipulations and the handling of the parts necessary to drilling holes in the bone for the insertion of silk or silver sutures, I do not employ that method of suture, but content myself with catgut or silk sutures placed only in the fibroperiosteum, or sometimes running across the front of the bone from the ligamentum patellæ to the tendon of the quadriceps. The rent in the capsule on each side is an important condition because of the lateral shortening of the capsule which may be effected by the cicatricial contraction following its repair. It is desirable, therefore, that the sides of those rents should be brought closely together in order that their reunion may take place with as little interposition of the cicatricial tissue as possible. The approximation of the fragments may be sufficient to effect this adjustment in most cases, but I like to insure it when practicable by one or two catgut sutures closing each rent. I habitually use a central longitudinal incision, extending the whole length of the patella. A transverse incision, straight or curving, more readily exposes the rent in the capsule, and permits the easier application of sutures to those rents, but it divides more and larger blood-vessels, and the scar is, I think, not quite so desirable as the straight central one.

The method of operating, then, is as follows: A straight incision is made from a little above the center of the upper border of the upper fragment to a point a little below the apex of the lower fragment, and is deepened until the gap between the fragments is reached. The fringe, if one is present, is then raised from the surface of the fracture, and such clotted blood as may be adhering to those surfaces is scraped off. Then two sharp retractors are passed into the gap between the fragments and hooked under them, and while the fragments are lifted by them the joint is thoroughly washed out with a hot, sterile salt solution. This is then removed with a sponge, and the fragments drawn together, usually by a tenaculum engaged above the upper fragment to draw it down. The fringe is spread out over the fragment from which it has been torn, and two or three catgut or silk sutures are passed from the periosteum of one to the periosteum of the other. I engage these sutures at a little distance from the edge of the fracture, say one-fourth inch, passing the needle transversely for one-fourth or one-half inch on each fragment, so as to give a better hold in the fibroperiosteum. Then with a sharp retractor one side of the incision is drawn firmly aside so as to expose the rent in the capsule, and a suture is placed across it close to the patella, and sometimes a second beyond it. Similar sutures are placed on the other side. The incision in the skin is then closed with silk sutures, and dressings applied. The limb is placed upon a Volkmann's splint, and at the end of about a week the skin sutures are removed. Two or three days later a plaster-of-Paris splint is applied and the patient allowed to get up, and even to go home, if he desires. At the end of a month the plaster splint is cut down longitudinally in front, and the patient is told to wear it during the day and leave it off at night. The reason for wearing it during the day is to prevent sudden accidental forcible flexion of the knee, for in such an event the upper fragment might easily be prevented, by loss of mobility of the capsule or by its temporary retraction, from swinging around the lower end of the femur, and thus the lower frament might be forcibly torn away from it and refracture produced. During the second month the joint should gain rapidly in freedom and range of motion, and by the end of that month flexion to a right angle will, in all probability, be present, and the splint may be discarded.

Discussion of the methods of non-operative treatment and the measures which may be indicated after failure of union, or after union with disability, must be left for another occasion.

MEDICAL PROGRESS.

A Rival of the Famous Crowbar Case. — Barritt (*Lancet*, January 7, 1899) gives the details of a case which fairly rivals the famous instance in which a Vermont quarryman, while tamping home a blast, exploded the same and lost one eye, by reason of the crowbar passing clear through his head, entering below his chin and passing out through the frontal bone. He recovered and lived some years in unimpaired vigor, and his skull now adorns the Warren museum in Boston. Barritt's patient was a lad, aged fourteen, who rammed a muzzle-loading gun with a thirty-inch iron rod. The gun was cocked and had a cap on. The jar brought down the hammer, and the ramrod, which measured $\frac{5}{8}$-inch in diameter at its big end, passed point foremost into the boy's forehead over his left eye, and out of his left parietal bone. He walked 200 yards to the house, and rode three miles to a hospital. In three weeks his wounds were so far healed that he went home. There was a discharge during convalescence of a thimbleful of bits of gray matter of the brain. The aphasia and partial paralysis of the right arm which followed the accident gradually disappeared.

Traumatic Rupture of the Heart.—NEWTON (*Medical Record*, January 21, 1899) was summoned to see a healthy man, aged twenty-eight years, who, while riding rapidly, was thrown to the ground by a break in the head of the bicycle. He apparently clung to the handles and struck his chest with great force against a portion of the tubing attached to them. He staggered a few feet and then fell. He died in about ninety minutes. The skin was not broken, but showed the imprint of the broken end of the tube. The sixth costal cartilage was broken and its outer fragment had been driven against the heart with sufficient force to make a triangular tear in the right ventricle near the apex. The pericardium was not ruptured. In the forty odd cases of traumatic rupture of the heart which have been reported, in almost every instance there has been disease of the heart. In such cases the force necessary to rupture the organ is very slight.

The Influence of Alcohol on Muscular Work.—DESTREE (*Quar. Jour. of Inebr.*, January, 1899) has made a number of experiments to determine whether more work can be accomplished with alcohol than without it. The results obtained were uniform, and clearly showed that:

1. Alcohol has a favorable effect on the work product whether the muscle is weary or not.

2. This favorable effect appears almost immediately, but is very transitory.

3. Immediately afterward alcohol has a very decided paralyzing effect. About a half-hour after taking alcohol the muscular power reaches a maximum that subsequent doses increases with difficulty.

4. The paralyzing effect of alcohol outweighs the momentary stimulation, so that the total work-product obtained with the use of alcohol is less than that obtained without it. In other words, alcohol is a deceptive means of dulling the sense of fatigue, but its action is momentary, and in the end injurious, the paralyzing effect upon the nervous system increasing rapidly, and with such force that any momentary good effect cannot counterbalance them. Similar experiments with tea, coffee, and kola showed that the stimulating effect of these drugs, while less marked than that of alcohol, is continued longer, and is not followed by a paralyzing effect, as is the case with alcohol.

Pulmonary Hemorrhages in Different Months.—GABRILOWISCH (*Berl. klin. Wochen.*, January, 1899) by keeping careful records of 380 patients during a period of five years, found that 213 of them, or 56 per cent., at some time had a pulmonary hemorrhage. In 30 per cent. there was only a single hemorrhage. An interesting feature of his records is the fact that nearly all the hemorrhages occurred in the spring or fall of the year. Sixty-four patients who had hemorrhages and were carefully observed for one year with reference to this point, passed April, May, June, and July, without a single hemorrhage. For August, September, and January, there were recorded in each 2 hemorrhages. The greatest number occurred in February, March, and October, the numbers for these months being 14, 18, and 16, respectively.

If further records substantiate these data, it will be of considerable importance to a patient; for he may then know at what time of the year he needs to be especially careful.

Fistula between Ileum and Bladder.—MARCY (*Annals of Surg.*, January, 1899) mentions the case of a woman, aged twenty-six years, married but childless, who, after an attack of peritonitis, felt something give way in the abdomen, and soon after passed thin yellowish matter from the urethra. Sometimes there were attacks of cystitis afterward, and the passage of brownish-water, containing occasionally the seeds of berries, convinced the patient that there was a connection between the intestine and bladder. At operation such a communication was found between the fundus of the bladder and the ileum, about eight inches above the ileocecal valve. The fistula was one-third of an inch in diameter. The parts were easily restored to their normal relations, but cystitis persisted. A similar case occurred in a child aged eighteen months, presumably due to an attack of appendicitis, but in that case the intestine and bladder both communicated with the outside world through a common fistula. There was no cystitis, and the recovery after operation was prompt and perfect. Fistulas of this character are rare, while those between the bladder and rectum are relatively common.

THERAPEUTIC NOTES.

Treatment of Eczema by Naphthalin.—AKHVLEDIANI (*Rev. de Therapeut.*, January 15, 1899) has treated forty-three cases of acute and chronic eczema with naphthalin. If the eczema was moist he first applied a powder composed of 2 grains of salicylic acid, and 1 ounce each of oxid of zinc and talcum. When the area had thoroughly dried, he applied an ointment of lard containing ten per cent. of naphthalin. The dressing was applied every morning after the parts had been cleansed with soap and hot water. Pains and pruritus disappeared in a week, and then the induration. After two or three weeks it was necessary to renew the bandages only every two or three days, and in three or four weeks the parts were entirely healed.

Nirvanin, a New Local Anesthetic.—LUXENBURGER (*Munchen. Med. Woch.*, January 3, 1899) has tested a newly discovered local anesthetic which is chemically related to orthoform and which bears the name, diathylglycocollamidooxybenzoesauremethylester, but which he calls nirvanin for short. He has found a two per-cent. solution to work best in practice. It produces in five to ten minutes an anesthesia which lasts for twenty minutes, and which is sometimes followed by an unpleasant burning and pricking, although the drug has no disturbing effect on the healing of the wound. It has the advantage over cocain of being slightly antiseptic, so that solutions even of the strength of one-half per cent. will keep sterile. If one prefers to sterilize it the solutions may be boiled without injury.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the Medical News will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

J. RIDDLE GOFFE, Ph.M., M.D., Editor,
No. 111 Fifth Avenue, New York.

SATURDAY, MARCH 11, 1899.

INFLUENZA COMPLICATIONS,—SOME RECENT DISCOVERIES.

The recent epidemic of contagious disease associated with affections of the mucous membranes and certain general symptoms we have come to call grippal, seems to have about run its course in this country. We are still reading about its continued spread in Europe. In Vienna at present it is adding seriously to the death-rate. The last English medical weeklies that have come bring accounts of its malign presence in various parts of England. Under these circumstances the last report of the investigations of the Chicago Board of Health, as reported in our Chicago letter of this week, have a special interest.

We expressed the opinion, when grip was said to be epidemic in New York City, that it was fatuous to call every epidemic involvement of mucous membranes grip. Influenza is an infectious disease due to an easily recognized bacillus, and the study of that bacillus and of its biology and pathogeneity in these cases would be much more important for medicine than the acritical grouping of a series of clinically varied affections under the convenient term grip. Our desideratum has been fulfilled by the Health Board of Chicago through careful investigations, in these cases, of the Canon-Pfeiffer bacillus, but with results exactly the opposite from what might have been anticipated. Instead of lessening the number of cases of influenza, careful bacteriological study has shown, as may be seen from the report, that when grip is rife it occurs as a complication in many diseases in which, although the symptoms are perhaps suspiciously atypical or irregular, there is nothing definite by which the presence of grip may be recognized clinically. As a matter of fact most of these cases escape even the suspicion of having in them an influenzal complication.

Not alone pneumonia, which has been known for some time to have tendencies to coquette with the bacillus of influenza, has been shown to be due in a number of cases to the Canon-Pfeiffer bacillus, but diphtheria has been found to be often complicated by it, and what seemed clinically to be diphtheria has proved on culture investigation to be due to a pure culture of the influenza bacillus. Still more striking is the fact contained in an additional memorandum from the Chicago Board of Health, and not embodied in its January report because the investigation was not yet completed. In a number of cases of what clinically seemed to be infectious parotitis, ordinary mumps, the influenza bacillus was found present in large numbers in the bronchial secretion.

These observations are extremely suggestive and do much to explain the atypical symptoms so often noted during supposed grip epidemics and the oft-noted tendency to the occurrence during such periods of other ordinary diseases and usually with more severity. The Chicago Board of Health is to be sincerely congratulated on the good and timely work it has done in the matter. We hope to hear more of it.

HEART WOUNDS AND THEIR PROGNOSIS.

It is interesting to note the change that has come over medical opinion in the last few years with regard to the fatality of wounds of the heart. The prognosis of even slight wounds of the organ was formerly considered absolutely unfavorable. When animals were encountered in whose hearts appearances were noticed (and they were not infrequent) that we now know to have been the result of

healed cardiac wounds, it was thought that these were due to congenital anomalies or acquired pathological changes, but not traumatic in origin. Penetrating wounds were set down as unfailingly mortal, but we have changed all that. Only the other day here in New York the coroner found a bullet in the pericardial sac which had plowed a way for itself through more than an inch of heart substance, yet the patient had lived for fourteen days after the shooting.

In the present issue of the MEDICAL NEWS Dr. Burtenshaw reviews the results of more than 100 cases of paracentesis pericardii, in only one of which was there any serious result, though the varying position of the heart in pericarditis makes it almost inevitable that it should have been more or less injured a number of times. There is, of course, no serious reason why a simple non-penetrating wound of the heart should ever cause death of itself, and even in cases of traumatic penetration Nature has shown that she has some marvelous resources at her command that make for conservation of the organism even under most unfavorable circumstances.

Laforgue's statistics of the results of heart wounds, all of which seem to have been substantiated by autopsy, are very striking. The reports of the cases in which cure occurred were collected from the post-mortem records years after the injury had been received, death having been caused by some other agency. In 56 cases of wounds of the heart, 18 were followed by immediate death, 21 patients survived for longer or shorter periods, and 17 completely recovered. Among the recoveries, in 4 cases the wound was inflicted by a pointed instrument, 6 times by a cutting instrument, 4 times by bullets, and in 3 cases by other forms of violence. It is clear that the manner of the violence does not influence the prognosis much. Even wounds of one coronary artery are not always fatal. Twice a healed lesion of the anterior coronary artery has been found at autopsy long years after the infliction of the heart wound.

A very important class of wounds of the heart, and much more fatal than might be imagined from the seeming insignificance of the injury and the instrument causing it, are those due to the voluntary or involuntary piercing of the heart by needles. Out of twenty-three such cases recorded by Terrier fourteen were fatal. The direction with regard to these cases is the immediate extraction of the needle, not the gradual removal that used to be advised. The wound of entrance is so small that loss of blood through it need not be feared, and delay in extraction has been the serious factor in these cases.

In the prognosis of heart wounds a good deal depends on the location of the lesion. Professor Rehn of Frankfort, whose report of a case in which he successfully sutured the heart after a penetrating wound turned attention generally to the possibilities of conservative surgery of the heart, gives his views as to the prognosis of any special wound of that viscus about as follows: It is not so much the clot that forms as the contraction of the heart-muscle itself that is the active agent in stopping hemorrhage. Where the muscle is thickest the danger of hemorrhage is least. Though the pressure of blood in the left ventricle is much higher than anywhere else, and this might suggest the conclusion that wounds here would be very easily fatal, the thick muscular wall usually serves as an excellent preventive of serious hemorrhage. Wounds of the right ventricle are not so favorable; of the auricles still less. Fortunately, the base of the heart where danger is greatest is protected by the bony sternum in front of it which turns aside many an otherwise fatal injury. In attempts at suicide the popular notion that the heart lies much lower in the thorax than it really does saves many a poor mortal from accomplishing his fatal purpose.

STEAM AS A THERAPEUTIC AGENT IN UTERINE HEMORRHAGE.

PROFESSOR DUHRSSEN of Berlin presented this subject and advocated the procedure at the last German Surgical Congress, giving due credit, however, to its inventor, Sneguireff. A condensation of his paper, with some later suggestions, appears in a recent number of the *Archiv für klinische Chirurgie*. As Professor Dührssen announces that he "can heartily recommend steam as a valuable addition to effective gynecological therapeutics," the subject seems quite worthy the attention of the profession in this country.

Professor Dührssen has found the intra-uterine steam douche of great service in all forms of uterine

hemorrhage, and especially (we quote his exact words) "in severe exhausting metrorrhagia in patients of forty and over, due to chronic metritis, with or without simultaneous hypertrophy of the uterine mucous membrane, and in obstinate uterine hemorrhage, due to abnormal friability of the uterine blood-vessels, or to the development of interstitial myomata." He has used it with extremely satisfactory results in cases in which the bleeding was so copious and uncontrollable that total extirpation of the uterus seemed the only alternative. He considers that his experience with it justifies him in saying that in this simple procedure every practitioner has a ready method at hand "without narcosis, without operative intervention, without causing the patient much pain (for the procedure is practically painless), of controlling uterine hemorrhage that threatens to be fatal, and in certain cases of saving patients from the serious operation of uterine extirpation which in their anemic condition would be extremely dangerous."

As Professor Dührssen is a well-known gynecological authority, not only skilled in operative work but placed in a favorable position for it whenever he deems it necessary, this expression of opinion must be considered sincere and should be allowed its fullest practical application. The technic is extremely simple: a spirit lamp is sufficient for heating water in any closed vessel to which a rubber tube may be attached for the conduction of steam. Even a domestic tea-kettle suffices if the top be tightly closed and the tubing attached to the spout. The rubber tube, as soon as a steady flow of steam is seen to be issuing from it, is slipped over a fenestrated catheter. This is inserted into the uterus, and the steam allowed to pass through. Two things must be carefully guarded against: the catheter where it touches cervical tissues must be thoroughly insulated by some non-heat-conducting material. Otherwise stenosis of the cervix is liable to result from cicatricial contraction induced by overheating. Professor Dührssen secures perfect insulation by slipping a rubber drainage-tube over the catheter at the point were it passes through the cervix. The second important precaution to be taken is that the steam must not be allowed to act too long, or the destruction of the entire mucosa will be followed by obliteration of the uterine cavity. Dührssen considers that, as a rule, one application of fifteen-seconds' duration is sufficient; this may be repeated later if necessary, and perhaps for a longer time. This intra-uterine steam douche has also been of life-saving service in cases of puerperal fever, especially those in which septic or putrid endometritis existed. Dührssen thinks it should form an excellent treatment for acute uterine gonorrhea. The gonococci may all be destroyed by a momentary application, and so all danger of the invasion of the tubes and ovaries precluded, a complication that none of the prevailing methods of treatment are able to prevent with any assurance, and the seriousness of which the whole of modern operative gynecology proclaims.

TYPHOID FEVER IN PHILADELPHIA.

WE print this week a protest from a Philadelphia physician against our arraignment of that city and its citizens for permitting the health of the inhabitants to be bartered away by a corrupt political ring; which ring holds the city councils in its grasp and absolutely refuses to allow the passage of any ordinance looking to the improvement of the city's water-supply with the accompanying assured prevention of typhoid fever. The best comment on that protest is the statistics of typhoid fever in Philadelphia during the very week that the protest was penned—FOUR HUNDRED AND TWENTY-ONE NEW CASES AND THIRTY-EIGHT DEATHS. We know these statistics show a much larger incidence of the disease and greater mortality than for the weeks immediately preceding and the reason is not far to seek. Following the severe wintry weather of the preceding weeks there was a thaw and contagious matter was washed into Philadelphia's water-supply, with the inevitable result. So it has been in the past; so it will be with every thaw this spring. Proofs are not needed, however, to convict Philadelphia's water-supply of being the cause of the prevalence of typhoid fever. There is no one whose opinion is worth considering who denies that.

It is sad to think that a Philadelphia physician should be found who practically defends this state of affairs. We cannot but think that our otherwise enterprising weekly medical contemporary in Philadelphia has been neglecting its duty in the matter of inculcating in the profession of the city proper sentiments on this subject. The patent-medicine abuse and the prescribing optician are deserving of atten-

tion but not to the exclusion of serious medical and sanitary questions like this. It is useless to deny the conditions that exist, it is almost criminal to attempt to palliate the evil that is so remorselessly carrying off its victims by the hundreds. What is needed is sincere, determined, united effort at reform.

Philadelphia's disgrace in this matter is known to the world and has been for years. The *New York Times* commenting editorially on our editorial on the subject said that no severer or more deserved censure of a city and its inhabitants was ever written. It especially insisted on our expression that "no Philadelphian should presume to raise his voice on any question of general interest and importance so long as this awful stigma attaches to the city."

It is a disgrace to every one who pretends to have any civic pride in the city in which he lives; a disgrace to all the intelligent voters, for it is a confession that they have sold their birthright to the politician's personal greed for plunder; a disgrace to the local clubs, founded for the purpose of instituting and maintaining clean politics and which now prostitute their influence to the lowest political purposes. After all, what matters it to them; they drink the sparkling bottled waters. But the poor who are unable to take this precaution, what of them? Great political clubs no longer have the mission they were supposed to have of guiding party action into proper channels; they have become the lounging places of those who fatten at the public crib.

Is there any one of ordinary intelligence in Philadelphia who does not feel acutely the awful disgrace of the present state of affairs? It is something that time will not remedy; it has grown worse not better during the last fifteen years. The extent to which the evil will spread during the next few years as more and more water is used for domestic purposes and the dangers of infection grow greater no one can foresee.

In two years the whole problem can be solved, the typhoid mortality annulled, the stigma of years wiped out. It has been done under much less favorable circumstances, in what we are pleased to call the Old World. It never will be done in Philadelphia until the too-conservative Philadelphians break from their disgraceful slavish submission to corrupt political parties and take into their own hands for the city's good and that of its citizens the management of municipal affairs.

A SUGGESTIVE DISCUSSION IN NEUROLOGY.

THE last meeting of the New York Neurological Society was of such general interest that we gladly give space in this number to an abstract of its proceedings. The discussion of Dr. Bailey's cases brings out clearly the modern view as to the lesion at work in most of the obscure cases of traumatic affections of the spinal cord in which the injury is not severe and bladder and rectum are not involved, yet the symptoms of actual lesion of the cord are clear, and the condition improves but slowly. Many of these cases come into the hands of the general practitioner, and it is well to know that while some years ago they were frequently considered as cases of intrameningeal hemorrhage, they are now generally thought to be cases of hemorrhage into the cord itself. Dr. George W. Jacoby's suggestion of the diagnostic and probable therapeutic value of lumbar puncture in these cases is a most welcome one, for, as a rule, the attendants' hands are absolutely tied and inaction in these cases is galling.

The most interesting phase of the meeting, however, was the discussion of two views that have been making important places for themselves in modern neurology. Dr. Hirsch's paper brought out the fact that the connection between infantile spinal paralysis in early life and spinal disease in later years is something more than incidental. The case he described is an apt illustration of the view, that is obtaining more and more adherents in these last few years, which postulates a relation of cause and effect, or at least of occasion and consequence, between the two spinal affections though separated from each other by a long period of years. Such latency for years, with subsequent pathogenic results, is not a new principle in pathology, but an exemplification of an old one which the history of tuberculous processes has made perfectly familiar.

The importance of this view as regards prophylaxis and the care that should be insisted on in the regulation of lives of subjects whose nervous systems have been crippled and rendered more liable to disease is evident, and makes a very practical contribution to neurology.

The further discussion of this case brought out another opinion not old in neurological circles as yet, that many of the so-called systemic diseases of the cord are really due to a diffuse progressive myelitis. There are those, we believe, whose opinions are of weight in neurological pathology, who hesitate to admit the existence of systemic or neuronic disease at all. Chronic inflammatory processes, with consequent overgrowth of connective tissue and progressive cirrhosis, are considered the real pathological condition underlying most diseases in the central nervous system. The new ideas are in the line of simplification, a not undersirable thing in neurology, and so deserve such thoroughly scientific discussion as was accorded them at the meeting.

ECHOES AND NEWS.

Serum-Cure for Pneumonia.—Professor Wasserman of Berlin, a pupil of Professor Koch, hopes that he has discovered a serum-cure for pneumonia.

Typhoid at Paterson, N. J.—There is an epidemic of typhoid fever at Paterson, N. J. Up to March 3d, twenty-eight cases had been reported. The epidemic is generally attributed to the Passaic River water.

A Hospital Closed.—The Staten Island Hospital closed its doors on March 2d after the last patient had been discharged. The managers announce that owing to lack of funds the maintenance of the hospital is to be temporarily suspended.

Lieutenant Wood Dies in Cuba.—First-Lieutenant James Wood, Assistant-Surgeon 202d New York Regiment, died on March 3d of pernicious malarial fever. Private Benjamin H. Davis of Company E., 1st Michigan, died of dengue fever.

The State Board of Charities.—Governor Roosevelt has nominated ex-Attorney-General Simon W. Rosendale (a Democrat) of Albany and Dennis McCarthy (a Republican) of Syracuse to be members of the New York State Board of Charities to fill vacancies.

Not a Pachyderm after All.—A school-teacher at Port Allegheny, N. Y., the other day received the following note: "My boy tells me that when I trink beer der overcoat vrom my stummack gets too thick. Please be so kind and don't interfere in my family affairs."

Hospital-Ship Sails for Manila.—The hospital-ship "Relief" with 200 hospital-stewards and nurses and a cargo of medical supplies has sailed from Norfolk for Manila. She will be used to carry sick and wounded soldiers from and to places in the Philippines.

To Fight Tuberculosis in Factories.—A section of the Central Federated Union of New York has endorsed resolutions calling for the appointment of a committee of labor men to cooperate with the Board of Health in preventing the spread of tuberculosis through neglect of sanitary laws in factories.

Bubonic Plague Raging at Bombay.—The Bombay correspondent of the London *Morning Post* states that the bubonic plague is raging in that city with unparalelled severity. During the week ending March 6th there were, according to the official returns, 972 deaths, but these quite underrate the mortality.

Military Surgeons to Meet.—Colonel Stark, secretary of the Association of Military Surgeons, has issued notice that the meeting, which had been postponed because of the war, will take place in Kansas City, May 24th to 26th, inclusive. All surgeons who served with volunteers now mustered out are invited to take part.

No Mercy for Mrs. Place.—At the monthly meeting of the Medico-Legal Society of New York, held on February 15th, a resolution was adopted to the effect that it was the sense of the society that the question of sex of the criminal convicted of homicide should be eliminated from the consideration of the executive in the exercise of the pardoning power.

To Elevate the Profession of Dentistry.—The American Academy of Dental Science of Boston and the New York Institute of Stomatology have combined in an effort to establish a higher professional plane for their department of medicine, to encourage journals independent of dental-supply houses, and to discourage the taking out of patents by professional men.

The Death of "Cavendish."—Henry Jones, who wrote treatises on whist under the *nom de plume* of "Cavendish," died on February 15th in London. He was by profession a surgeon, and was for twenty years engaged in active practice. In 1872, finding it impossible to do justice to both his literary and medical engagements, he decided to devote himself entirely to the former.

State Medical Examiners Reappointed.—Drs. George Ryerson Fowler of Brooklyn and A. Walter Suiter of Herkimer, representing the Medical Society of the State of New York, and Drs. Arthur R. Tiel of Matteawan and J. P. Nolan of New York, representing the Eclectic Medical Society, have been reappointed as their own successors on the State Board of Medical Examiners.

Age and Sleep.—Tesla says that negroes live to an advanced age because they sleep so much. He believes that a man has just so many hours to be awake and that the more of them he uses up in a day the shorter his life will be. A man might live to be two hundred if he could sleep most of the time. The proper way to economize time, therefore, is to sleep whenever there is nothing better to do.

Dr. Jenkins on the State Health Board.—Governor Roosevelt has appointed Dr. Wm. T. Jenkins of New York City a member of the State Board of Health to

fill a vacancy. Dr. Jenkins is Chairman of the Sanitary Committee of the New York City Board of Health, and it is provided that the member of the local Board of Health who holds that office shall be appointed a member of the State Board of Health.

A Member of the "Light Brigade" Dies —There recently died in Seattle, Washington, one of the "noble six hundred" who made the "Charge of the Light Brigade." He was Dr. Maguire. After receiving marks of honor for brilliant service in the Crimean War he resigned his service in the British Army to practice his profession in Australia, and afterward in San Francisco and Seattle. He was sixty-five years old when he died.

Medical Experts and Their Fees.—At the sixteenth annual meeting of the Society of Medical Jurisprudence, on the evening of February 18th. Justice William Rumsey made a speech in which he advocated the formation of public and professional opinion against the acceptance of fees by medical experts for testifying. The justice thought that experts should pass an opinion on facts brought out at the trial and that they should not help lawyers to bring out certain truths and withhold others.

Smallpox in Puerto Rico. — There are now about 1000 cases of smallpox in Puerto Rico, but there is little fear that the disease will spread beyond controllable limits. Dr. Azel Ames, Acting-Assistant Surgeon of the Hospital Corps, has begun the vaccination of the 1,000,000 inhabitants of the island in order to prevent an epidemic. A "United States Vaccine Corps" has been established at Cramo Springs. and it is expected the work of vaccinating will be completed before July 1st. The vaccine points are being prepared from cattle on the island.

Faith Healer Kills Himself.—Gottlieb Roehm, a faith-cure advocate, recently committed suicide in Brooklyn by taking rat-poison. It seems he could not live and endure the unbelief and the ridicule of his neighbors, one of whom had rheumatism and asked what he should do for it. "Tie a dog's tail to your leg," answered Roehm, "and if you have faith you shall be healed." The suicide left a note which read, "I have come to the conclusion that it is time for me to end my life. I have spoken to the Lord and it is with His consent that I do this."

Thick and Thin Lips.—Dr. A. Bloch, the French anthropologist, attacks the theory that thick lips denote sensuality, while thin and delicate lips denote spirituality, firmness, and elevated character. The scientist considers that the shape, size, and color of the lips are purely race characteristics, and that in the hybrid peoples of Europe and America, where there has been such an intermingling of races, a child may inherit from not very remote ancestors lip-forms that completely belie the actual character of the child, as indicated by the lip-theory. Dr. Bloch considers that really thick lips in the white races are always anomalies or freaks of Nature.

Another Christian-Science Manslaughter.—A man named Senior was recently convicted of manslaughter in England for allowing his child to die without medical aid. The case has been taken to a higher court and the conviction confirmed. The ground for the judgment was that the defendant had wilfully neglected his child. Seven of Senior's twelve children have died without medical aid being provided. This case shows clearly the difference between the death of a child and that of an adult. Harold Frederic being a grown person was supposed to be responsible for his own acts, and the charge against the Christian Scientists who treated him was therefore withdrawn.

Principles for Sale and—Sold.—Our Philadelphia contemporary is scarcely to be congratulated upon its early capitulation to commercialism as is evidenced in its issue of the 25th ultimo. The motto it early adopted "by the profession, of the profession and for the profession," sounded prettily and the austere code of advertising ethics announced in its opening issues possessed an alluring charm to those of the profession who feared the degenerating influence of commercial interests. How sadly potent is the sway of such influence may be measured by the brevity of the resistance offered by this champion of austere morals and its prompt surrender augers ill for the future of independent medical journalism.

New Yorkers Use Plenty of Water.—William Dalton, Esq.. Commissioner of Water-supply, in his annual report, states that the maximum daily supply of the system in Manhattan and the Bronx is 400,000,000 gallons. The reserve held in storage is 42,200,000,000, which, at the present rate of consumption, would be sufficient for the two boroughs for 182 days without the natural flow of the rivers from which the supply is drawn. During 1898 the draft on stored water for the old City of New York was 12,330,000,000 gallons. The minimum daily consumption in that year was 238,000,000 gallons in April, and the maximum 256,000,000 gallons in September. The average daily consumption was 243,000,000 gallons or 121 gallons per capita.

Artesian Wells in London.—A part of London suffered from a water famine last fall which caused people to inquire seriously as to what relief from present conditions can be obtained. It has been proposed to build an aqueduct from the Welsh hills. An easier solution of the problem seems to have been reached by some enterprising manufacturing establishments which have sunk artesian wells to a depth of more than 400 feet right in the city itself and have found an abundance of pure water. It is forced to the surface by means of compressed air. One concern pumps, in this manner, 840,000 gallons daily. A better idea may be gained of this enormous volume of water by saying that 117 such wells could keep the Croton aqueduct flowing at its full capacity.

Grip Increases Death-Rate.—There were 12,421 deaths reported to the New York State Board of Health during January, 1899. This was an average daily rate of 400. The number of deaths exceeds that of January, 1898, by 2800. From acute respiratory diseases nearly 3000 deaths were reported, 700 more than in December and

1200 more than in January, 1898. The increase was chiefly in pneumonia and acute bronchitis, which caused 23 per cent. of the total deaths. The most of this increase was due to the prevailing epidemic of grip, from which it was estimated that 1800 deaths occurred in December and 3000 in January. The mortality was relatively greatest in the rural parts of the State, the city of New York, with half the entire population, having but 600 of the 2800 increased mortality over January, 1898.

To Investigate Vaccination.—A bill has been introduced in the Assembly at Albany which provides for the appointment of a commission of five persons to be known as the "Commission on Prophylaxis of the State of New York," to investigate the nature and value of vaccination-serum, etc. The State Board of Health is to recommend to the Governor a physician who is in favor of the use of vaccination, antitoxin, and other serums as prophylactics, and the Brooklyn Anticompulsory Vaccination League of Kings County is to recommend a physician who is opposed to the administration of vaccine and serums. These physicians thus recommended will be appointed commissioners by the governor. The other three members of the Commission must be persons who have formed no fixed opinion upon the subjects to be investigated. The Commission is to hold office for two years.

The Weber-Parkes Prize.—The second award of the Weber-Parkes prize and medals by the Royal College of Physicians of London will be made in 1900. These awards are conferred triennially to the writers of the best essays upon some subject connected with the etiology, prevention, pathology, or treatment of tuberculosis, with special reference to pulmonary consumption in man. The subject selected by the adjudicators for the next award is: "The Etiology of Human Tuberculosis and the Assistance Which a Knowledge of the Etiology May Render to the Task of Prevention." The essay must be based on the original work and observations (experimental or other) of the author and must include a detailed exposition of the methods employed and their mode of application. The value of the prize is 150 guineas (over $760), and a silver medal is conferred as an enduring souvenir. A similar silver medal, distinguished as the second medal, will be awarded to the essayist who comes second in order of merit. The award will be made on some day previous to October 16th (St. Luke's Day) 1900.

The Greatest Achievement of 1898 —Perhaps the greatest advance in the medical world in the year 1898 was the very wide attention which was given to the prevention of tuberculosis. The medical papers were filled with articles upon the best method of treating the sick so that the well might be protected from contracting the disease. Not an association of medical men met without a discussion of this question in one form or another. Boards of health and legislative bodies passed measures and discussed plans for the special treatment of consumptives. In short, the public is awakening to the fact that it has been harboring in its midst, without thought, a parasite a hundred times more deadly to it than leprosy or cholera. Such an awakening may not be heralded with all the applause which follows the discovery of a new microbe or the X-ray, but the results which will follow will be of vastly greater importance to the community. In England, for instance, there was founded the "National Association for the Prevention of Consumption and Other Forms of Tuberculosis" with the Prince of Wales as its patron, and gifts amounting to £20,000 in its treasury.

CORRESPONDENCE.

THE HEALTH OF THE HAWAIIAN ISLANDS.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—It is conceded that inasmuch as this group of islands has become part of our national domain it is more than ever necessary that we know the truth concerning leprosy and diseases generally prevailing there; but no one with fair information on the subject can agree with the *Medical Record* (October 15, 1898) that "for many years the Sandwich Islands have been a hot-bed of disease, and until drastic remedial measures have been put into force are likely to remain so," etc. Dr. Morrow, a visitor in Hawaii, is quoted as saying: "The demographic effects of introduced disease in a virgin soil can nowhere be better studied, and they exhibit facts of most remarkable interest." The same writer then tells us of the ravages of measles and smallpox with the introduction of syphilis by Captain Cook's expedition.

It is the purpose of this paper to take the other side of the question, and in support of the views advanced I would cite as authority the Board of Health of Hawaii, the reports of the Government physicians (English and American), and those of the medical officers of the United States Navy, who have rendered statistical reports of disease from Honolulu for at least thirty year past; furthermore, the writer can claim a large and continual personal experience in the islands.

It has been said that the Commonwealth of Massachusetts is the best government in the world; in most respects, the Republican Government in Hawaii could challenge comparison. The Health Department of the Government was most ably conducted; the Board of Health represented the best intelligence of the community combining, as in Massachusetts, all the various interests in caring for the public health. Its earnestness, ability, and success is beyond cavil; utterly devoid of politics, its work was unhindered and to-day the money expended, the humanity shown by the Republic of Hawaii to the unfortunate natives will ever remain its greatest monument.

While the considerations here presented apply to Hawaii generally, in the matter of sanitation we will confine ourselves to Honolulu. The elevated portions and suburbs of Honolulu are, as a rule, in good sanitary condition; in the low and crowded old town, with its mixed population, there are undoubtedly bad conditions; the midden is in use, and there is no good system of sewer-

age; sewage is collected and carried to deep water. Another defect is the crowded harbor and the flats which surround it, which become covered with sewage. Furthermore, Honolulu needs more water. These conditions have all been recognized, a complete system of sewerage has been contracted for, and arrangements for storing and filtering water coming from the valleys back of the town has also been provided for. Indeed, when one compares these conditions with those prevailing in the United States in cities of similar population, Honolulu as to care and expenditure is infinitely superior.

Under the Board of Health are twenty-four Government physicians, who watch disease and disease-producing conditions, as is done in no rural district in the United States. This Board deals with details of public health in a far more careful manner than in large cities. The quarantine is as perfect as yet devised. The eradication of cholera in 1895 reflects the greatest credit on the Board of Health. The following is the death-rate in Honolulu during the nine months prior to December 31, 1894:

		Estimated Population.
All nationalities	21.14.	28,000.
Hawaiians	31.19.	10,500.
Asiatics	15.89.	9,506.
Portuguese	14.21.	3,800.
All others	16.66.	16,000.

In analyzing these figures, it will be seen that the general mortality is small despite the high native rate and that of the Asiatics, and that the European rate is about that of Newport, R. I.

Consumption, at one time unknown, is gaining daily. After perspiring freely, and then seeking to cool off in a fresh trade wind, all readily catch cold; almost all visitors have an introductory coryza, but among the natives this dread malady finds its greatest number of victims. Expressed briefly, it is mainly due to wearing foreign dress. Clothed in palm and pandanus leaf, the skin is in equable condition as to heat and moisture; in woolens and cottons the native takes cold, and succumbs more readily than the white. Beck claims that this is true in all the islands of the Pacific, when the missionaries insist on changing the primitive dress.

Fevers are common, very much like those of the Southern United States. Eight fatal cases of typhoid occurred in Honolulu in 1895. Tropical fevers are still much unstudied, both clinically and bacteriologically. The nomenclature is geographical; thus there is Syrian, Walchren, jungle fever, etc. Cadge calls jungle fever a remittent, but those who have had experience well know the difficulty of classification. The conclusion that all fevers are paludal is inaccurate; a wetting, undue solar exposure, too free use of alcohol and of food suited to cold climates play an important part. Most tropical fevers are continued; as a rule they are ushered in with diarrhea. Headache is unusually severe; many show no improvement under quinin; the microscope fails to find the plasmodium in many cases otherwise showing malarial symptoms. The writer has never seen an intermittent fever in the tropics. The term periodical is much less applicable than in the United States. Diarrhea is so early and persistent it may be considered the essential element in many cases, the fever being a septic symptom.

Diseases of the digestive tract, diarrhea and dysentery, prevail just as they do in the Southern States. Pneumonia and bronchial troubles are on the increase. Diphtheria is a *questio vexata*. Dr. Alvarez reports finding the Klebs-Loeffler bacillus in cases submitted to him. Rheumatism is very unusual. The exanthematous fevers are very rare, with the exception of measles. Scarlatina is not reported. The amount of venereal disease is greatly exaggerated (*vide* reports of Bureau of Medicine and Surgery, Navy Department). The cruiser "Baltimore" suffered less while at Honolulu in nine months than she did after one week at Hongkong from this class of disease. The following are the reports of venereal cases for Honolulu for 1896 and 1897.

1896.		1897.	
Number on register	116	Number on register	128
Hawaiians	32	Hawaiians	25
Half-castes	7	Half-castes	5
Japanese	74	Japanese	96
German	1	German	1
French	1	French	1
S. S. Island	1		

The question of greatest importance concerning leprosy seems to be, Is the disease being crushed out? Will our new political relations bring us great danger in this regard? The demographic statement of Dr. Morrow has been widened into a demographic law, and that is, "The black races perish and disappear in contact with the white." This is no new fact; our own country has worked the problem with the Indians; it is in process all over the Pacific under conditions as inevitable as that of coral formation. A race of weak vitality, like the indolent Hawaiians, has no power to resist the ills of Pandora's box let loose upon them.

The statement that leprosy is on the increase is borne out, if one relies only on a superficial investigation. Between the years 1866 and 1895 the number of inmates of the leprosy-station at Molokai increased from 165 to 1087. The explanation is simple. Under the Republic segregation was vigorously pursued, and a great rounding up resulted in having practically all the subjects at Molokai or at the observation-station at Kalihi. The opposition to segregation has in a great measure ceased; instead of secreting relatives and living secluded in the mountains, the natives now see the justice and even comfort at Molokai. Incipient subjects are carried there now, whereas under the monarchy only confirmed cases of long standing were taken in; thus the mortality has decreased, and the number steadily increased.

Of the twenty-four Government physicians, the majority state there is no leprosy in the district or note a few cases; one or two note no change; some admit that many cases brought to them are syphilitic. Cases found now are of a mild type, rarely tubercular, or with the facies leontine. As is well known, the disease rarely attacks the white population. During the biennial period ending December 1, 1897, there were 6 cases in the white race, *viz.*, Portuguese, 2; German, 2; American, 1; English, 1. Alluding to the venereal origin suggested by Morrow, is it not singular that in all the years the United States has kept a large naval force at Honolulu not a

seaman or marine has ever been reported as being leprous? As to the *Record's* idea of sending observers and scientific investigators to Hawaii, the fact remains that men of high scientific ability resident in Honolulu have for years studied this disease clinically and bacteriologically. Dr. Alvarez leads in this work in Hawaii, and was a recognized leader at the Berlin conference, being placed second on the general committee, and his method of diagnosis is recognized as the best. Our Government had an official representative at Honolulu last year, and he will readily admit his inability to do more than has been or is being done.

In view of our large commerce with the islands in the past without the introduction of Hawaiian leprosy into California (though it does come in from China), in view of the disappearance of the native race, which has fostered the disease, with a stringent quarantine against Asiatics, I submit that leprosy loses most of its significance as a cause of future trouble to the United States. If ordinary care as to health matters be exercised, and I claim that more than this is done, that most magnificent of ventilators, the trade wind will keep Hawaii salubrious and sweep away deleterious agencies that arise there. These winds blow from the mountains over the town to the sea. During the short period of reversal, or when the southwest wind occurs, all feel the change, and sickness is greater. The natives call this the *kona* or sick-wind, but its duration is short. Assuredly it cannot be assumed that the sickness among the United States troops at Honolulu is climatic; it is the same old story of large bodies of men congregated, the authorities among whom are either ignorant or oblivious of lessons learned long ago in camp sanitation and the health of armies.

JOHN C. WISE, M.D.,
Medical Inspector, U. S. N.

U. S. S. "BALTIMORE,"
CAVITÉ, PHILIPPINE ISLANDS,
January 20, 1899.

COMPARATIVE MORTALITY FROM TYPHOID FEVER IN PHILADELPHIA.

To the Editor of the MEDICAL NEWS.

DEAR SIR: — Philadelphians are so accustomed to the misrepresentations of the lay press of New York where their city is concerned that its deliverances have ceased to attract their attention, but expecting better things from the medical press on account of its pretention to science which exacts strict impartiality, I confess to surprise at the impassioned philippic against our city in your issue of February 18th.

While I do not intend to attempt a defense of the presence of typhoid fever in Philadelphia I wish to show by statistics that the deaths from that disease here are not so excessive when compared with those of some other cities which hold their heads very high hygienically as to justify the dreadful penalty that "no Philadelphian should presume to raise his voice in any question of general interest and importance."

Very little value is to be attached to inferences drawn from the record of the deaths of a single week, the real worth of statistics being in direct proportion to the number of facts collated; I have, therefore, in what is to follow made use of the annual death-rates for six years in different cities as compiled by Dr. John S. Billings in his reports of vital statistics for the last United States census. These reports were of course made up from those prepared by the registration officials of the several cities.

According to this authority in the six-years-period ending May 31, 1890, the following was the average annual death-rate per 100,000 persons living from the below-named diseases in four cities (Vit. stat. New York and Brooklyn, p. 33; vit. stat. Philadelphia and Boston, p. 26):

	NEW YORK.	BROOKLYN.	PHILA.	BOSTON.
Typhoid fever.....	24.37	23.13	69.35	39.02
Malarial fever.....	24.62	32.62	7.21	1.75
Diarrheal diseases....	316.85	282.58	70.31	102.54

Reading these figures literally it would appear that the deaths from typhoid fever in Philadelphia were proportionately nearly three times those in New York and Brooklyn, and not quite twice those in Boston. But what is the meaning of the excessive mortality from malarial fever in New York and Brooklyn as compared with that in Philadelphia and Boston? Is it possible that the first two cities, although situated farther north than Philadelphia, are more exposed to the malarial poison, or have the physicians in those localities not yet learned the antimalarial virtues of cinchona bark, notwithstanding that this knowledge has been the common property of the profession for more than two hundred years? Neither of these reasons is, of course, to be entertained and it seems to me most probable that nearly all the deaths reported as from malarial fever should be classed as from typhoid fever, or at least they would be so designated in Philadelphia. I know that formerly in the death reports of New York City "typhomalarial fever" was recognized as a special cause of death at a time when all deaths reported to the health authorities at Philadelphia from this cause were classed in that city under "typhoid fever."

Assuming that I am correct, if the deaths from typhoid and malarial fever be added together, the following figures will result:

	NEW YORK.	BROOKLYN.	PHILA.	BOSTON.
Typhoid and Malarial fever.....	48.99	55.75	76.56	40.77

This is quite a large mortality in each of the four cities from a malady which in your opinion is "an easily preventable disease."

To tax your patience a little longer, Mr. Editor, if we now consider the statistics which you quote in holy horror from your Philadelphia correspondent relating to the ravages of typhoid fever in Philadelphia, and which figures I believe to be correct, it would appear that in the last ten years there has been an average number of 500 deaths from the disease for each year. Taking the average population of Philadelphia during those years at 1,000,000, which is certainly below the mark since the population is now estimated at about 1,300,000, the typhoid death-rate during those years would have been 50 to the 100,000 persons living, or about the same as that in the six-years period quoted above for New York

from typhoid and malarial fever combined; less than that of Brooklyn from the same, and about twenty per cent. in excess of that of Boston. And yet I do not remember any such frantic appeals to those cities on account of such mortality or threats of putting them out of the pale of civilization for not correcting it.

Again dealing with the figures of Dr. Billings and of your correspondent I call your serious attention to the fact that the typhoid death-rate in Philadelphia for the six years ending May 31, 1890, was 69.35, while for the last ten years it was but 50, showing a decrease of nearly thirty per cent. Unless Philadelphia has had a wonderful streak of good luck in these years she appears to have been doing enough to escape at least your charge of "crime" in her negligence.

I have quoted the death rates from "diarrheal diseases" in the several cities—astounding in their excess in New York and Brooklyn over those in Philadelphia and Boston—simply as a hint that some typhoid cases may have unobserved crept under this caption in the death-lists of the first two cities. R. A. C.

PHILADELPHIA, February 23, 1899.

We can easily understand how the physician who sends us the above subscribes only his initials for publication. His letter boiled down and in plain English would read something like this: "Our death-rate from typhoid in Philadelphia in not so very bad. It is ever so much worse than that of any other large city in the civilized world we know, but that is our business not any one else's. Let us alone." Are there any physicians in Philadelphia who would care to sign that statement as it stands?

Then the awful attempt at defense! "Very little value," he says, "is to be attached to inferences drawn from the record of the deaths of a single week." Very little value to be attached to the fact that among a million of people 40 die in a week from typhoid, and over 400 are stricken with the disease? Human life must be of very little value in Philadelphia. Though these are the figures for a single week is there any pretense that they are much above the average for certain seasons of the year? Nearly as many deaths occurred in the week before that for which these statistics were quoted, practically as many (38) occurred the very week our correspondent wrote his letter.

Then comes the manipulation of statistics, and the statistics for what years? For the six years preceding 1890! Do they know in Philadelphia that the rest of the country claims to be in the year of grace 1899? We have heard that a P. R. R. brakeman, when asked by a traveling Englishman who had been told that he would have to put his watch back at each of our large cities on his way West, what was the difference in time between New York and Philadelphia, promptly replied, twenty years. We have thought that this was an impious exaggeration, or at least that the medical fraternity in what used to be the medical center of the United States did not share in the general backwardness, but here is a medical man who defends the present condition of Philadelphia in the matter of typhoid by statistics gathered more than fifteen years ago. We spoke of the last ten years, and we said the last of these ten years was the worst of them all, and we see no reason to change that expression.

The next point in the defense is a most curious one. It presumes that there is no malaria in the North at all, and adds to that the assumption that the medical men of other cities than Philadelphia (this is typically characteristic of a certain class of Philadelphians) were in the habit of mistakenly diagnosing about one-half of their typhoid cases as malaria. He wipes out Philadelphia's mortality from malaria by adding it to the typhoid column in order to be able to do the same thing for New York and Brooklyn. Does he not know perhaps that Philadelphia has some undoubted malaria in the low-lying districts near the Schuylkill, and that any such manipulation of her statistics is unwarranted? He must know absolutely nothing of the state of affairs around Brooklyn and New York or he would at least allow us the privilege of having *some* malaria. Believe us, dear, good sir, the medical profession are not all fools outside of Philadelphia.

Need we discuss these puerile manipulations of statistics further? We ask every Philadelphia physician to read once more our correspondent's defense of the present state of affairs with regard to typhoid in Philadelphia, and then to realize what the position is which he himself occupies. Let it not be said at least that the medical profession has stood idly by and seen this awful sacrifice consummated year after year unmoved and without loud and frequent protests. There may be a few old fogies, like our dear, good, doubtless well-meaning correspondent, in the medical profession in Philadelphia, men of other times who do not realize that typhoid has become an easily preventable disease. To those men no appeal can hope to penetrate; they are enwrapped in an armor of conservatism to which harveyized steel is as nothing in its power of resisting penetration. But Philadelphia's fair name is a precious heritage to the younger generation of Philadelphia physicians. Let it be no longer smirched as it has been. Unite every effort to make the city's sanitary condition a model to the world—not the awful example that it is. Philadelphia is situated not unlike Berlin as regards the room that it has in which to spread out. Read the wonderful municipal lessons of the model city that the Prussians have made out of their capital while it was growing as almost no other city in the world has ever grown.

MEDICAL MATTERS IN CHICAGO.

[From Our Special Correspondent.]

REPORT OF ORIGINAL WORK ON THE BACILLUS OF INFLUENZA.

CHICAGO, March 6, 1899.

DR. F. E. WYNEKOOP, First Assistant Bacteriologist of the Chicago Health Department, has made a preliminary report of original observations in which he has demonstrated that after one has become familiar with the appearance of the Canon-Pfeiffer bacillus under the microscope, it may be readily identified in the sputum and mucus of an influenza patient by direct examination, with-

out awaiting the process of incubation. In the course of examinations made in the laboratory of the health department for suspected cases of diphtheria prior to the appearance of influenza in this city early in December, 1898, a very small bacillus was occasionally found which, in its morphologic characters, corresponded to the organism described by Pfeiffer. With the increase of influenza these organisms were found more frequently, and in order that more extended observation might be made, physicians were asked to send specimens of the sputa and mucus of their influenza patients to the laboratory, and culture outfits were prepared for this purpose. These were put up in the same manner as those used in the diagnosis of diphtheria, except that the blood-serum contained more hemoglobin.

Human blood-serum was at first used, but finding that the serum of beef's blood containing hemoglobin answered every purpose it was finally used altogether since it was readily procured. Upon this medium cultures were made from the mucous membrane of the tonsils and pharynx and from the bronchial secretions of persons ill with influenza. In many of these cultures the small organism above referred to was found, and in a few instances in a state which was almost pure. From the cultures which were comparatively free from other bacteria transplantations were made to bouillon, a drop of which was immediately transferred to the surface of blood-serum. Three tubes or boxes of serum were usually inoculated from the same drop, and by this means isolated colonies were usually obtained in the second or third tube. The organism isolated in this manner was found in many cases of clinically typical influenza, and in its morphologic, biologic, and pathogenic characters it conforms to the one described in the works on bacteriology. The size and shape are the same and when examined in the sputum so also is the arrangement. Usually the bacilli were found solitary, sometimes in short chains. When a slide was made from a culture, however, they were more often seen in masses. Carbol-fuchsin seem to be the best stain. Other staining solutions were used but were not satisfactory. When an examination was made after a culture had been incubated eight or ten hours the organism stained quite evenly, but after thirty-six- or forty-eight-hours' incubation the characteristic uneven staining was noticed. When blood-serum was used exclusively as a culture-medium growths were obtained that were characteristic and beautiful. The colonies were clear and transparent and in a measure resembled minute drops of water or dew. The life cycle is exceedingly short and uncertain. The culture frequently dies within two days unless transferred to fresh media. In bouillon the development occurred very slowly and in some instances not at all unless a little blood or hemoglobin were added, which caused a more abundant growth. The culture-broth did not become cloudy but remained clear, and the colonies were noticed at the bottom of the tube as irregular whitish-gray masses.

Some observers report finding the bacillus in the blood of influenza cases, but the organism does not seem to occur in the circulation except occasionally. In forty-three blood examinations made by Klein bacterial forms were absent in thirty-seven. In the other cases "the same minute bacillus" was found; in one case the bacilli were present in great numbers; in two they were fairly abundant, and in the other three very few were to be found. In the examinations made in the laboratory in no instance was the bacillus discovered. Cultures were also made from the blood but no growth was obtained. It is thought by some that when the bacilli do occur in the blood they are present as dead and not as living bacteria. If this be true the finding of them cannot be considered as of pathognomonic value or their absence of diagnostic importance.

Dr. Wynekoop's recent experience seems to show that a bacteriologic diagnosis can best be made by means of cultures as described above or by direct examination of the bronchial secretions. The culture method requires from ten- to fifteen-hours' incubation, which time is necessary for the growth of the organism. After it has thus developed, however, a diagnosis can be made with but little difficulty. When direct examinations were made of mucus from the tonsils and pharynx before the use of antiseptics the results were very satisfactory, the bacilli being found in the majority of cases. The latter method has the advantage of giving an earlier diagnosis and seems to be quite as reliable.

After becoming familiar with the bacilli one can in most cases easily recognize them in the secretions. Occasionally specimens will be met with which contain very few organisms, and in these cases some time may be required in order to make a certain diagnosis. In many specimens of bronchial secretions examined in the laboratory the influenza bacilli were found at once and the diagnosis made without delay. This is not difficult when carbol-fuchsin is used as a staining agent as it colors the influenza bacillus in a very decided manner.

Certain of the pneumonia organisms closely resemble the influenza bacilli. The lanceolate bacillus, for example, is quite similar in microscopic appearances. Upon close observation, however, it is seen to be a little longer and with ends which are more pointed. It is more easily stained than the influenza bacillus, and its ends do not become so deeply colored. The colonies on blood-serum are not so clear and transparent, but have a tendency to become somewhat opaque.

In several instances the bacillus of diphtheria and the bacillus of influenza were found at the same time in the throats of patients, and the clinical symptoms usually supported the bacteriologic findings. This was true also with several other disorders. It would seem that a bacteriologic diagnosis in influenza is of special advantage in detecting this disease when complicating other diseases. The bacilli were not only found present in cases of diphtheria but also in cases of scarlet fever, measles, and pneumonia. In all of these conditions it was noticed that there were clinical manifestations which were difficult to interpret until the microscopic examination was made.

In the diagnosis of suspected diphtheria during the past two months some interesting observations were made relative to obscure clinical symptoms of influenza. In cases which appeared at the onset to be diphtheria the presence

of the Canon-Pfeiffer bacillus was demonstrated, and the subsequent course of the disease confirmed the microscopic diagnosis of influenza. In many of these cases the throat symptoms were so marked—redness and swelling of the tonsils and a well-developed membrane—that a physician would not hesitate to pronounce the case diphtheria, yet influenza bacilli were often found in these cases in a condition almost pure. Cases with little throat disturbance, but with temperature, bodily aching, and general depression, were on the other hand found to be mild diphtheria, although the clinical symptoms pointed strongly to influenza. In cases apparently of tonsillitis the influenza organism was found, and in other cases, which were clinically severe laryngitis, these bacilli alone were present in the expectorations. In these atypical manifestations of influenza very few of the general symptoms of the disorder were noticed, and the diagnosis, subsequently confirmed by the course of the disease, was made solely on the bacteriologic finding.

It has occasionally been observed by physicians that when influenza was present in a household the eyes of some members of the family suddenly became acutely inflamed, accompanied by severe pain, swelling and redness of the conjunctiva, with a profuse discharge of pus, of medium consistency and cheesy appearance. As the disorder differs materially from ordinary acute conjunctivitis, it was suspected that the bacillus of influenza might have something to do with the diseased condition. Cultures were made from the discharges and the suspicion was verified by finding great numbers of the influenza organism. Experiments are now being made upon the eyes of guinea-pigs with pure cultures of the bacilli, and it is hoped soon to be able to report further concerning this additional manifestation of the ubiquity of this malefic microbe.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

AN ANTIVACCINATION BILL BEFORE THE LEGISLATURE—LIPOMA OF THE FILUM TERMINALE—GASTRIC CARCINOMA—THE MEDICO-CHIRURGICAL COLLEGE WINS ITS SUIT—BEQUESTS TO HOSPITALS—BOARD OF HEALTH NOTES—HEALTH STATISTICS.

PHILADELPHIA, March 7, 1899.

THE bill introduced in the State Legislature, repealing the law requiring from all children entering public schools a certificate of vaccination, has received much attention from the press, the laity and the profession and equal condemnation from all concerned. The executive committee of the Public Education Association has characterized the bill as a vicious measure and has asked the House and Senate committees having the bill in charge to postpone action until "the friends of public health can be heard." The College of Physicians at a meeting March 1st, adopted resolutions protesting against and condemning the bill, stating that such a measure "is unwise, dangerous, and a step backward in sanitary matters, and will expose the community to increasing danger of an epidemic of smallpox and to consequent incalculable injury to health and immense loss of commerce of any community in which such an epidemic may occur."

C. Oscar Beasley, representing the so-called American Antivaccination Society, gave the press a statement as to the position of the society on the matter and after stating that there is an alarming amount of ignorance among physicians on the statistics of the efficacy of vaccination and that many of the most eminent physicians in the world oppose vaccination, which fact is studiously concealed by its advocates, he gave some facts and statistics which would make Munchausen a sorry competitor of the gentleman. That such action can be taken by any mentally well-balanced individual seems incredible and at a public hearing to be held March 14th, for evidence pro and con, it is to be hoped that the matter will be settled once and for all time by digging a grave both wide and deep for the bill and its scatter-brain advocates.

At a meeting of the Pathological Society, held February 24th, Dr. William G. Spiller presented a case of "Lipoma of the Filum Terminale." The specimen, interesting because of the rarity of such tumors, was accidentally discovered in a case of tabes dorsalis and this was true also of the only other similar case on record. The growth was probably due to misplaced tissue in the fetus. Another interesting case presented at the same meeting was a "Carcinoma of the Stomach" which Dr. W. E. Hughes exhibited. Interesting facts were the patient's previous symptoms of gastric ulcer, recovery, and ten years later the occurrence of carcinoma with the presence, until four months of death, of hydrochloric acid in the gastric juice.

The Supreme Court of Pennsylvania has affirmed the decree of the Court of Common Pleas in granting the petition of the Medico Chirurgical College asking for authority to confer degrees in dental surgery, from which the Philadelphia Dental College took an appeal. The opinion, which was delivered by Judge Dean, holds that the word "medicine" in its common signification, includes all learning having for its object the care of the health and the cure of the ills of the human body, and, inasmuch as the Medico-Chirurgical College has authority to confer degrees in medicine, it unquestionably has the right to impart instruction in dentistry and to confer degrees in that branch.

Hannah Price Brookfield, who died last month, in her will admitted to probate last week, bequeathed $10,000 to the Jefferson Medical College Hospital for free beds in memory of Dr. J. M. Brookfield and his wife Sarah Price Brookfield. To the House of Mercy for Consumptives, at Chestnut Hill, $2000 was left and the remainder of the estate is to be divided among a large number of homes, etc.

Dr. Augustus A. Eshner has severed his connection with the *Philadelphia Medical Journal* of which he was assistant editor.

Dr. Percival E. Loder is temporarily delivering the lectures on anatomy at the Pennsylvania College of Dental Surgery in place of Dr. J. Ewing Mears. Dr. Mears, who has handed in his resignation to the board of trustees, felt that the student body had not treated him with due

respect and hence took this action. Should Dr. Mears' resignation be accepted it is possible that Dr. Loder, who is demonstrator of anatomy, will be elected to the chair of anatomy.

The Board of Health has recently discussed the question of compelling proprietors of lying-in institutions to report to the board within five days the date, place of birth, mother's name and address; name, sex, and color of the child and, in case of adoption, the name of the person desirous of adopting a child, no child being allowed to be adopted until the board is satisfied that the child is to be adopted by responsible people. The institutions were represented by an attorney who contended that it put unfortunate women to unnecessary shame. After some discussion by Colonel J. Lewis Good and Dr. Charlotte Abbey the matter was referred to the Sanitary Committee for further consideration.

Mayor Ashbridge evidently wishes the power of appointing his own health officer for a bill has been introduced into the State Legislature abolishing the present Board of Health and providing for the establishment of a Bureau of Health as a subdivision of the Department of Public Safety. Should the bill be carried the mayor will, of course, have control of the appointment of the chief of the bureau and of the subordinate officers composing it.

Doubtless the threadbare tale of more typhoid-fever cases is growing monotonous to every one and just as we grow accustomed to any excesses when repeated again and again so *443 new cases, an increase of 22 over last week*, seems a trifle. Chief Medical Inspector, Dr. Taylor, said he could not remember any week in which there had been so many deaths from typhoid as there were last week, and this record for number of cases and deaths has never been equaled in the records of the city. At the rate of the average number of cases for the past month or so the number of cases for the year will be somewhere near 20,000 and the deaths probably 2000. Comment is useless.

The total number of deaths occurring in Philadelphia during the week ending March 4th, as reported at the health office, was 566, of which number 129 occurred among children under five years of age. The total number of new cases of contagious diseases was 523, reported as follows: Diphtheria 56 cases with 16 deaths; scarlet fever 24 cases with 2 deaths; typhoid fever 443 cases with 49 deaths.

OUR LONDON LETTER.

[From Our Special Correspondent.]

VACCINATION AND ANTIVACCINATION AGAIN—A CURIOUS CASE OF LEAD POISONING—GOOD ADVICE TO MRS. 'ARRY 'AWKINS ABOUT THE CARE OF THE LITTLE 'AWKINSES—THE HARDENING EFFECTS OF FORMALIN—THE NEW INEBRIATES' ACT AND THE POSITION OF THE GOVERNMENT.

LONDON, February 26, 1899.

GREAT disappointment is felt in medical circles that no mention of revaccination was made in the Queen's Speech, the equivalent of our President's Message, at the opening of Parliament. Of course this does not necessarily mean its omission from the Government program, but it is usually expected that all important measures in view will be at least alluded to in the Speech. As was intimated in my last letter, the consent of Lord Lister and other influential medical men to the "experiment" bill containing the conscience clause was only gained by a definite promise of adequate legislation in regard to revaccination at the next session of Parliament, a promise which was publicly repeated in the House of Lords by Lord Harris on behalf of the Government. By making revaccination compulsory, except in cases of "conscience," between the ages of twelve and fourteen, it is hoped by forcing the question upon the attention of recalcitrant parents a second time to double the chances of overcoming their resistance, and thus perhaps an even greater percentage of the population would get vaccinated first and last by two non-compulsory insistences than by the old single compulsory effort.

Much as the profession distrusts the sincerity and utterly condemn the rationality of the antivaccination propaganda, yet it really begins to look as if there were some reason after all in the hope of some perhaps too optimistic and tolerant spirits among us, that it would begin to collapse of its own accord if deprived of the arguments based upon "brutal tyranny," "martyrs for the right," etc. A most curious state of affairs has just developed at Oldham, which enjoyed the bad eminence of no less than 27,000 exemptions since the Act went into effect. These to become valid must be filed with the health-officer within a certain period and this has now expired without a considerable per cent. having been so filed. Not only this, but the vaccinations reported to him in January alone considerably exceed the number for *the entire year* previously. During the past month 200 children were vaccinated in Oldham, while during the whole of 1897 there were 183 only, and in January, 1898, only 10. In Burnley, where the appalling number of some 7000 exemptions had been granted, 2000 have never been called for by the applicants and still lie in the clerk's office. It would really seem as if the sturdy Briton suddenly finding to his surprise that if he wanted to make a fool of himself the law was not going to forcibly prevent him, had gone quietly home and for the first time began to think over the matter.

A curious case of death from lead-poisoning has just been reported. A girl employed in a factory where lead-glaze is used died suddenly with saturnine symptoms. At the inquest it was shown that the death was in no way the fault of the manufacturers as the deceased had been in the habit of surreptitiously eating cake and buns during work-hours, in spite of the company's stringent rules against any eating on the premises. Naturally, of course, under such conditions, the cake was eaten with unwiped fingers and a rapidly fatal poisoning was the result.

An excellent step has just been taken by Dr. George Millson, medical officer of health for Newington, one of the most crowded districts in London. This is the issuing by the vestry, or local municipal council, of a circular, entitled "General Directions—How to Feed and Bring up Infants." The district is frightfully overcrowded, early marriages are the rule, especially among the costers,

and the intelligence of the girl-mothers may be judged from the character of some of the "directions" found necessary. "Do not give a baby cheese, beer or tea," it might be profitably added "gin"; "Infants must be kept warm" and should be "washed all over with soap and warm water at least once a day." Dr. Millson is anxious to organize a scheme for teaching the people the elements of nursing and hygiene through a staff of trained nurses who should be sent to every house where serious illness occurred, not so much to take charge of the cases, but to teach the family what to do for them and how to do it. It would be an admirable and most beneficent idea.

Another abortionist has been convicted of "constructive murder." This time it is a woman, Jane or "Nurse" White, for causing the death of Alice Birmingham, in November last, by an illegal operation. Although women are not hanged for such a crime and the jury brought in a strong recommendation for mercy, yet the whole ghastly farce of the black-cap and "to be hanged by the neck till you are dead" was solemnly gone through with. Next week we shall hear the sentence has been commuted to three- or four-years' imprisonment.

An ingenious and most successful application of the hardening effects of formalin has just been reported in the *British Medical Journal* by Dr. William Mitchell. An inoperable fungating sarcoma of the face came under his care and as the hemorrhage was becoming serious in spite of all ordinary styptics, he applied pledgets of cotton soaked in a strong solution of formalin. The effect was not only to promptly check the hemorrhage but to "mummify" the whole surface-layers of the growth to a depth of nearly half an inch. This tissue being perfectly anesthetic was curetted and cut away and the application repeated until the entire growth was removed, layer by layer, without a dram of hemorrhage, in the course of a few weeks. As the formalin seemed to penetrate the growth more deeply and completely than it did the surrounding tissues, the borders of the former were mapped out both to sight and touch with great distinctness after each application and the removal could be made both complete and exact. The only drawbacks to the method were the pain which, though quite severe both during and for some hours after each application, was readily borne with the assistance of small doses of nepenthe, and the edema produced in the surrounding tissues. Any one who has seen the striking effect of formalin in congealing dead tissues and its rapid "tanning" effects upon his own fingers will be inclined to believe that we may find in it a most valuable means of holding in check or removing inoperable neoplasms according to Dr. Mitchell's ingenious suggestion.

In a few weeks more the new Inebriates' Act will come into practical operation but it is a disappointment to know that the Government has decided not to provide funds for the building of reformatories until they find by actual experience about how numerous the convictions under it are likely to be. However, luckily, several private institutions of this class have signified their intention of applying for a license under the Act and others are to be provided by various philanthropic associations, so that those convicted will not be branded with the prison-stamp by being cared for in certain departments of existing penal institutions. The new law is such a marked and rational departure from previous principles of legislation that its results will be watched with great interest by both medical men and penologists. We of New York may take a special pride in it, as it is in principle, practically the application to inebriety of the Elmira or Brockway system of indeterminate confinement, the length of which is based upon progress made toward reform. After a certain number of convictions for drunkenness, the inebriate will be committed to one of a series of carefully regulated reformatory institutions under the general supervision of medical inspector Dr. R. W. Braithwaite. The Act is a triumph of the medical view of inebriety, that, however we may differ as to its voluntary and controllable character in its beginning, after a certain stage it becomes a disease and its victim should be treated as a patient, not a criminal.

The Parliamentary Bills Committee of the British Medical Association has just held its most important session before the opening of Parliament. Its attention was principally occupied with the final revision of the Midwives' bill which is to be presented this session. The subcommittee upon this subject reported that the Midwives' Institute had also prepared a bill and an attempt had been made to harmonize the two documents. The principal points of disagreement seem, however, to be important if not vital ones. The Midwives' bill defines a midwife as "any woman who for gain undertakes to attend women in childbirth" while the medical committee insists upon the addition of the important qualifying clause "under medical control and supervision," thus limiting the powers of the midwife very properly but to an extent hardly likely to be relished or accepted unless inevitable by the good ladies themselves. Make them mere subordinates of the doctor and they will soon be supplanted by the trained nurse and the advanced student-assistant, a consummation devoutly to be wished. The other point relates to the composition of the central controlling Midwives' Board which is to examine candidates, issue and revoke licenses and supervise practice. This the Midwives' Institute bill wishes to consist of six members, four of whom shall be physicians and one of these to be appointed by the institute itself. The medical bill provides that all the members are to be registered medical practitioners appointed by the Medical Council, so as to represent the various sections of the country.

The Subcommittee on Revaccination also met and agreed to prepare and push a bill requiring revaccination to be made obligatory at the age of twelve years.

To Relieve Chilblains and Habitual Cold Feet.—JONES of St. Bartholomew's makes use of hydrofaradic baths at bedtime. Hands or feet, as the case may be, are placed on flat electrodes in a vessel containing tepid water, and as intense a current as can be borne is turned on for ten or fifteen minutes. The inflammatory symptoms are subdued, the treatment being repeated as indicated. Permanent cures of cold feet are reported after ten treatments.

PRECAUTIONS AGAINST INTRODUCTION OF THE PLAGUE INTO EUROPE—APPENDICITIS AMONG SOLDIERS—COMBINATION OF ETHER AND MORPHIN FOR PATIENTS WITH WEAK HEARTS—THE TIME TO OPERATE IN APPENDICITIS—THE GOOD EFFECT OF BICYCLE RIDING UPON INGUINAL HERNIA—UNSUCCESSFUL SUTURE OF THE RIGHT VENTRICLE—LIGATURE OF THE UTERINE ARTERIES FOR CARCINOMA OF THE UTERUS—THE DISCUSSION OF THE SURGICAL SOCIETY UPON THE OPERATIVE TREATMENT OF APPENDICITIS — TUBERCULOSIS OF THE TONSIL AND SOFT PALATE—PRIMARY SYPHILITIC LESIONS OF BOTH BREASTS—PURULENT FOCI IN THE LUNGS, RECOGNIZED WITH DIFFICULTY.

AT the Academy of Medicine, January 17th, PROUST read a paper upon the defenses of Europe against the plague. Sparsely inhabited and desert-regions afford great protection, but communication with infected districts in Asia, by railroads and steamship lines constantly exposes the countries of Europe to a visitation of the disease. To prevent this it is not necessary that any more councils be held; it is only needful that the rules laid down by the conventions of Vienna, Dresden, and Paris be carried out. Unfortunately, the rules regarding the quarantine of vessels coming from infected ports and for the disinfection of those which have carried persons ill with the plague are not always followed with the desired thoroughness. In some instances captains of ships, and even medical officers have falsified their reports in order to prevent delay.

At the session of January 24th, CHAUVEL reported the results of the treatment of 171 cases of appendicitis occurring in the French army. About one-half of the patients were subjected to operation. The mortality in this group was slightly higher than in the group of those treated medically. This was due party to the fact that for the most part only the graver cases were brought to the operating-table, and partly to the length of operative manipulations. Operation is always indicated if suppuration is present or seems likely to arise, while the cases without suppuration may safely be placed under a rational medical therapy.

FERRAND suggested that the injection of half a syringeful of ether at the same moment that morphin is administered to weak persons. The ether is well borne, does not in any way interfere with the anesthetic effect of the morphin and it reduces the danger of syncope and embarrassment of the respiration.

At the session of February 3d, DIEULAFOY said that he had operated in 61 cases of appendicitis in the last three years, with 7 fatalities, that is, a mortality of 11.4 per cent. If these figures were high it was not on account of the difficulties of operation, but because the patients had been kept upon medical treatment too long before the surgeon was consulted. This was a most reprehensible practice, since medical treatment gives a mortality of at least 30 per cent. Surgical treatment is the only rational one, provided that operation is performed at the earliest possible moment after the beginning of the attack.

RECLUS endorsed these opinions and advocated immediate operation in all cases in which the progress toward recovery is not absolutely evident, and unless the patient is so situated that the symptoms can be constantly observed and operation performed at any time. It is well to remember that one can never predict the moment in appendicitis upon which its outcome depends.

LUCAS-CHAMPIONNIERE reported a case of cure of an inguinal hernia by the continued use of the bicycle. He considered the repose so often ordered to those who have herniæ very injurious. It is evident that those engaged in an active occupation do not suffer nearly so much from their ruptures as those who are able to live without exercise. A patient should be encouraged to engage in sports of every kind, and of all of them bicycle riding is the very best. When a man is mounted on a bicycle the hernia has no tendency to come down, but remains in the abdominal cavity, and tends to become fixed in that position, and so a cure is effected. Besides its local good effects, riding improves the general health and reduces the flesh of the patient. It should be so arranged as to produce the greatest benefit. The saddle should be low and broad, and set well behind the pedals, and the amount of exercise should be slight at first, but gradually increased as to grades and speed. Patients who have had a radical operation for hernia may safely be trusted to begin their rides two weeks after the operation.

At the Anatomical Society, January 13th, BUFNOIR showed the heart of a man who had been shot with a 22-caliber revolver through the sixth left intercostal space. Misled by the direction of the ball, the surgeon opened the abdominal cavity, but finding no blood there he explored the pericardium and found it full of clots. These were removed and a wound in the right ventricle was sutured. The patient died. The autopsy showed a second wound, that of exit, in the posterior wall of the right ventricle.

February 3d, LOEWY presented the pelvic organs of a woman who had died from the pressure of cancerous growths upon the ureter. Five months before her death the uterine arteries had been ligated. Technically, the operation was a perfect success, but it had afforded no relief to the patient. From a study of this and other cases, the speaker had concluded that ligature of the uterine arteries for carcinoma of the uterus is not a good operation. When the tumor is yet small the uterus should be removed; and after the time for that operation has passed relief from bleeding can be much better obtained by cauterization through the cervix than by arterial ligation.

At the Surgical Society, January 18th, SCHWARTZ opened a discussion upon the treatment of appendicitis which occupied the attention of the members during that meeting and the following two. He advocated an expectant treatment in acute attacks, deferring operation unless there were signs of commencing peritonitis. If the symptoms completely disappear, no operation is necessary. If pain and constipation and resistance continue, it is better to operate in the interval.

GUINARD operates in an acute attack if there are signs

of an abscess. He prefers to operate in the interval, and does not think it necessary to await a second attack.

REYNIER said that certain cases are too serious for operation. He mentioned in illustration the case of a diabetic woman who had a thready pulse and fecaloid vomiting. Her condition was such that he felt assured she could not have lived through an operation. Under medical treatment she recovered completely. In three serious cases he had operated at once, and the patients had all died. In four other serious cases he had waited until the conditions improved, and then had operated with success.

LEJARS said that operation is urgently indicated in cases with abscess formation, and in cases with septic symptoms whether due to perforation or to a diffuse peritonitis.

WALTHER preferred to delay operation in grave acute cases, unless there were indications which demanded immediate interference, as he considered the prognosis better the longer one waits.

KIRMISSON did not believe that one can lay down absolute rules for the treatment of acute appendicitis. One ought to operate immediately if suppuration or peritonitis manifests itself. Especially in infectious cases in children should there be no delay.

JALAGUIER said that if there is a tendency to a localization of the process operation is more dangerous than medical treatment, by opium, ice, enemata, and rest. If the process is spreading, injections of serum offer the best chance for recovery.

QUENU expressed himself in favor of immediate operation if the patient is seen in the first day or even the second day after the beginning of the attack. If called to a case in the fifth or sixth day, he was inclined to await firm adhesions, watching the patient with great care meanwhile.

TUFFIER said that the only question in the minds of most men is when to operate. If a case is seen soon after the onset of the symptoms he thought that immediate operation should be performed just as in intestinal perforation or strangulated hernia. In the last two years he had seen nine patients succumb after a delayed operation, all of whom he felt sure might have been saved by an early operation. Other patients have by the merest chance been saved after a late operation, as recently happened when the seven-year-old son of a colleague was operated upon on the seventh day of the trouble, and the perforation was found to be prevented only by the serous covering of the appendix. The sole reason for delay is the desire to be able to operate more safely in the interval, and delay subjects the patient to risks of suppuration and peritonitis which no one can foresee.

BRUN said that he operated immediately only in the presence of septic peritonitis. In all other acute cases he instituted medical treatment. Improvement was generally manifested in a few hours. If there was not a markedly better condition of the patient in twenty-four hours, he operated. The other patients were submitted to resection of the appendix, after the acute symptoms had subsided.

NIMIER had treated eight patients by injections of artificial serum, and all of them recovered, and had had no recurrence.

CHAPUT advocated immediate operation in all acute cases of appendicitis. If the statistics of operation in the interval were made to include the failures of medical treatment of acute cases, the results would be worse than the results of operation in the acute stage. In twenty acute cases without peritonitis he had operated with twenty recoveries.

At the Medical Society of the Hospitals, January 20th, BARBIER mentioned a case of tuberculosis of the tonsil and soft palate, which seemed to come from direct infection as the husband of the patient died of pulmonary tuberculosis one year previously. No lesion of the lung could be made out in the wife, nor was there expectoration. The diagnosis of tuberculosis of the palate was confirmed by bacteriological examination.

DANLOS showed a wet-nurse, aged thirty-six years, with numerous lesions upon both breasts, which were considered to be primary syphilitic chancres. The child she had nursed had died of hereditary syphilis soon after its birth. The woman's own child had also been nursed by her, but it gave no evidence of having contracted syphilis. The chancres had a secreting surface, a slightly sloping border, and were indurated. There was an indolent enlargement of the axillary glands. There were nowhere else on the body evidences of syphilis.

At the session of January 27th, GUINON spoke of the uncertainty of physical examination in purulent collections in the chest. A woman who had fetid purulent expectoration for three months was examined by five skilled physicians who could make out nothing except subcrepitant râles. She grew worse, hemoptysis developed, and the chest was opened and a large pus-cavity was found in the superior lobe. She improved somewhat but died later of repeated hemorrhages.

TUFFIER said that he had performed pneumotomy seventeen times, and that in seven of these cases there had been an error in diagnosis, although the patients had been examined by the most distinguished physicians. Such errors are more likely in connection with the inferior lobe. Radioscopy is a great assistance in such cases.

BECLERE mentioned ten cases in which diagnosis of interlobular purulent foci had been made by radioscopy. The method was however not infallible as shown by the fact that he had mistaken for a case of this character one which was afterward proved to be an aortic aneurism.

SOCIETY PROCEEDINGS.

NEW YORK NEUROLOGICAL SOCIETY.

Regular Meeting, Held Tuesday Evening, February 7, 1899.

THE Secretary, DR. JOSEPH COLLINS, in the Chair.

DR. BAILEY presented two cases of

TRAUMATIC LESIONS OF THE CERVICAL CORD,

the patients now in course of recovery. In the first case the previous history showed nothing of importance except

perhaps a typical musculo-spiral palsy with drop wrist, which came on as the result of injury some years ago, and might perhaps be thought to indicate special sensitiveness to trauma on the part of the nervous system. The present condition dated from a fall into an area which had rendered the patient unconscious. He came to, to find himself in Bellevue Hospital. A deep scalp wound showed that he had landed on his head. There was tingling and paresis on both sides, and in all four extremities, but no sphincter trouble. There was especially pain and stiffness in the neck, and numbness of the right side. Gradually the condition has improved though there still remains some paresis. Sensibility is dulled in the right arm, and there is profound anesthesia of the right leg. The lessened mobility of the neck may be seen from the constrained position in which the head is held. There is also evidence of some sympathetic disturbance. There is a distinct difference in the width of the palpebral fissures, and the right pupil is wider than the left, and does not react to light. The diagnosis of the case would seem to be a crushing of one of the intervertebral disks, with one or more slight hemorrhages into the substance of the cord.

The second case was that of a man on whose head, while he was wedged immovably in an elevator-shaft, the balance-weights of the elevator descended. The result was a superflexion of the head on the breast with consequent traction upon the cord. He was taken unconcious to the New York Hospital, and has gradually recovered. There is a well-defined area of complete anesthesia over the right shoulder and above the clavicle. There is a blunt feeling all over the right side, especially in the right arm. There is no deformity. All the reflexes are heightened in the arm and leg on the left more than on the right. There is left ankle-clonus. Fibrillary twitchings are to be noted in the muscles of the neck. In this case exaggerated flexion of the neck would seem to have caused hemorrhage into the cord. The prognosis of both these cases of hemorrhage into the cord is reasonably good.

In the discussion Dr. Fisher said that he has under observation at present a case not unlike those of Dr. Bailey's only more serious and more lasting. The patient is a boy who was thrown violently forward, and his head forced down upon his chest while playing football. He was unconscious for over an hour and then had complete loss of power and absent sensibility in all his extremities, but no bladder or rectal symptoms. There was some improvement after awhile, but the reflexes continued heightened, and there was wasting of muscles. The anesthesia gave place to numbness. He recovered sufficiently to walk, the right side being more wasted at first. Later on atrophy of the muscles on the left side developed. The support of his head on a jury mast has been followed by more regular improvement. In this case Dr. Fisher has considered that the lesion was a hemorrhage outside of the cord in the membranes, or some slight dislocation causing pressure upon the cord, the recovery with spastic symptoms pointing to this rather than to hemorrhage within the cord itself, though this latter lesion would better explain the atrophy of muscles that has ensued.

Dr. Jacoby suggested that in such cases lumbar puncture might be of the greatest service. If there was blood in the subarachnoid space the cerebrospinal fluid would be tinged, and it would indicate hemorrhage within the cord. In these cases the lumbar puncture would probably also be of therapeutic service, relieving tension within the cord by the evacuation of a certain amount of the fluid and encouraging absorption of what remained before the continued pressure had set up chronic inflammatory changes.

Dr. Bailey in summing up said that intrameningeal spinal hemorrhage is so extremely rarely found in pathological examinations, that one hesitates to diagnose it without absolutely pathognomonic signs. He had never seen it himself in any of the cases he had had the chance to examine post-mortem. Stolper who had made a great many autopsies in cases of injury of the cord doubts entirely the occurrence of intrameningeal spinal hemorrhage alone without other complications. It seems more advisable then to consider that the cord lesion in these doubtful cases of spinal trauma is hemorrhage into the cord itself.

Dr. Lecynzski presented a patient with spastic symptoms of the legs and general loss of tone and feeling though with absence of local atrophy. There were no contractures and no ankylosis though a certain amount of talipes equinus was present. The man had fallen two stories and landed on his buttocks. Immediately after the accident there had been loss of power and sensation. Improvement had taken place until the present spastic condition had been reached. A very interesting phenomenon in the case was that the knee-jerks were absent, yet ankle-clonus present. This is not a very unusual phenomenon, and is not as paradoxical as it seems. It always occurs when the injury is limited as in this case to the lumbar region. The symptoms point to a traumatic condition of the cord, very probably hemorrhages into its substance, between the tenth dorsal and the upper sacral segments. A very interesting phenomenon in the case also is a gluteus clonus that may be brought into play by tapping the buttock. A series of contractions and relaxations of the large muscles here is set up which it is impossible for the patient himself to control. They can only be stopped by flexing the limb on the trunk. The direction which the contractions take show that it is not the gluteus maximus, as might be thought at first, that is mainly concerned in these clonic contractions, but the gluteus medius, whose fibers run the other way.

Dr. Collins demonstrated the brain of a case of sensory aphasia, in which the lesions found post-mortem, especially the atrophy of the first left temporal convolution, confirm the clinical diagnosis and show that the localizing symptoms of the character of the aphasia may give absolutely sure signs for the diagnosis.

Dr. William Hirsch read a paper, entitled

ON THE RELATIONS OF INFANTILE SPINAL PARALYSIS TO SPINAL DISEASES OF LATER LIFE.

He demonstrated microscopic sections of the spinal cord

of a patient whom he had presented to the New York Neurological Society more than two years ago. It had been the general opinion then that the case was one of amyotrophic lateral sclerosis of the spinal cord, or that it was progressive muscular atrophy. The microscopic sections show that it was a speading myelitis. The overgrowth of connective tissue in the cord seems to have begun in the scar of the old poliomyelitis that the patient had had as a child. Especially marked was the proliferation of connective tissue around the blood-vessels and the fan-like processes of connective tissue running out from the anterior, and at times posterior horns, of the cord to the periphery of it. The case seems to be another link in the chain of evidence that is gradually accumulating, and will perhaps eventually discredit, or at least greatly limit, the application of the theory of systemic, or as Dana prefers to call it, neuronic disease of the central nervous system. It seems also to add weight to the opinion of many who connect etiologically acute anterior poliomyelitis of early life with nervous disease which develops later on. In this case what was thought to be amyotrophic lateral sclerosis, or progressive muscular dystrophy, proves to be a progressive myelitis. Dr. Hirsch thinks that all cases of trophic paralysis like this developing years after anterior poliomyelitis are really chronic progressive myelitis.

DR. JACOBY, in discussion, mentioned a case in which cerebral hemorrhage in a child had been followed years afterward by encephalitis, and thought that the original lesion had so reduced resistive vitality of the nerve-centers as to predispose to the pathological condition that developed.

DR. COLLINS thought that Dr. Hirsch's case was no more than a chronic myelitis developing in a patient who had incidentally had acute anterior poliomyelitis years before which had gotten better.

DR. FISHER did not think that the scar of a healed poliomyelitis could be reasonably supposed to contain virulent material which, being set free after decades had passed, might cause myelitis, and thought the processes independent except, perhaps, for the lack of resistive vitality induced by the former nerve-lesion.

DR. HIRSCH, in conclusion, restated his view that myelitic processes are commoner and more important than they are usually thought to be and that the cicatricial remains of anterior poliomyelitis may be their starting-point.

THE PHYSICIAN'S CODE OF ETHICS NOT NARROW OR ANTIQUATED.[1]

ON the occasion of the installation of the officers of the New York County Medical Association, which took place at Mott Memorial Hall, New York City, on the evening of February 20, 1899, the newly elected president, Dr. Frederick Holme Wiggin, in his inaugural address referred at length to certain portions of the National Code of Medical Ethics about which there seemed to be much misapprehension. He began by disavowing the slightest intention of stirring up old strifes, and claimed that he had selected this special topic solely because, in his intercourse, not only with his professional brethren, but with various men of affairs, he had been impressed with the fact that certain very important parts of this subject were very generally misunderstood. For instance, only a very few months ago a high official in the Homeopathic State Medical Society had told him that when the American Medical Association and its affiliated societies were ready to open their doors to those who held different views from the majority as to the action and dosage of drugs, he, for one, would be willing to leave his organization, discard his sectarian title, and apply for membership. This gentleman, like many others, was not aware that years ago the American Medical Association had taken this very position.

In spite of all that had been said since regarding the code of medical ethics, the members of the medical profession in this country had lived under it in reasonable harmony from the organization of the American Medical Association in 1848 until 1882. In the latter year the first note of discord had been struck by the New York State Medical Society which, at its annual meeting in Albany, had adopted a different code. As this was in direct violation of one of the by-laws of the national organization, the judicial council of the latter society, by a unanimous vote, excluded the New York delegation. As a result, the members of the profession residing in this State who still desired representation in the national body were constrained to organize the New York State, and the New York County, Medical Associations. This division of the profession, with its resulting dissensions, was especially unfortunate, because it arose from a misunderstanding, and was, therefore, wholly unnecessary. The American Medical Association had endeavored to clear up any doubt upon the main question at issue, that of consultations with homeopathic practitioners, by adopting in May, 1884, a series of resolutions, making clear the fact that the national code contained no provision in any wise inconsistent with the broadest dictates of humanity and the exercise of the most perfect liberty of individual opinion and practice, and that the true ground for declining professional fellowship with any class of practitioners was not a belief in any particular dogma, but the adoption of sectarian names as trademarks, and the formation of organizations antagonistic to the great mass of the medical profession. This action of the national body, Dr. Wiggin said, had certainly opened the door years ago for the return to the parent organization of the members of the New York State and County Societies, and that the members of the County Society now appreciated this fact, and occupied identically the same position, was evident from the inaugural address, in 1897, of its president, Dr. Arthur M. Jacobus, who, in speaking of certain sectarian practitioners, said: "If they will but drop the sectarian title for that of physician, pure and simple, and let the old and new school questions die out, I am sure we will welcome them with open arms."

In closing his address Dr. Wiggin said that although the local profession might be compelled to wander a few years longer in the desert of disorganization, it was fair to predict that early in the Twentieth Century a Moses would be found who would lead the profession into the promised land of union and strength. When that gladsome time should arrive when all educated physicians in this State would join hands, he hoped the larger and reorganized society would adopt, as its motto, a paraphrase of that of the famous Musketeers of Dumas—"The profession for the individual practitioner, and the individual practitioner for the profession."

[1] Abstract of the Inaugural Address of the President of the New York County Medical Association, Dr. Frederick Holme Wiggin, delivered February 20, 1899.

VOL. LXXIV. NEW YORK, SATURDAY, MARCH 18, 1899. NO. 11.

ORIGINAL ARTICLES.

RABIES AND ITS PREVENTIVE TREATMENT: AN ANALYSIS OF CASES.[1]

BY FOLLEN CABOT, M.D.,
OF NEW YORK;
ASSISTANT-BACTERIOLOGIST TO THE NEW YORK CITY DEPARTMENT OF HEALTH.

I BELIEVE hydrophobia to be a rare disease in the human being, but comparatively frequent in certain animals. I make this statement only after a careful study of the subject during a period of about two years. I have studied reports of cases appearing in Germany, Austria, France, and England, and of investigations in rabies which have been made in those countries.

In this country the subject has received more attention of late years, and although there is still some confusion and many wrong ideas in regard to the nature of rabies, investigators who have studied the disease thoroughly and scientifically agree in all essential points. That there are a great many wrong impressions in regard to the disease and its various manifestations is apparent to nearly all of us. Medical men and men outside the profession with only a superficial knowledge of the subject, expound their views and give most learned opinions on the least provocation in a way which makes one who realizes the vastness of the subject almost envious. Before entering into a discussion of the three divisions of this paper, I wish to say a few words about some of the obstacles to be overcome in obtaining a clear idea of a rare but nevertheless important disease.

On February 4, 1899, a dog on Staten Island bit three people; a "mad-dog" scare was started, and many people were considerably alarmed. Perhaps the dog was mad; perhaps it wasn't; all dogs which bite people are not mad. However, as there had been several mad-dog scares before on Staten Island, some of which were well founded, as I will show you presently, it seemed very important on account of those bitten and for the future welfare of the people in that part of the city to prove whether or not the dog died of rabies. The dog was captured by the agents of the Society for the Prevention of Cruelty to Animals and confined. During its confinement of between two and three days it showed some symptoms which could be produced either by rabies or by one of several other diseases. It died on February 7th, three days after the people were bitten, and was sent, not to the Department-of-Health Laboratory, but to another laboratory. So far so good; it made no difference to us whether the examination was made in one place or another so long as it was done thoroughly and according to the best scientific teaching. We learned, however, that no inoculation-tests were to be made, and as these tests are the only reliable ones we have at present, to prove the presence or the absence of the disease in a suspected animal, I applied by telephone to the president of the Society for a part of the medulla and spinal cord of this dog, explaining to him that the above-mentioned test was absolutely the only one at present relied upon by scientists to prove the presence or absence of rabies. I said I was especially anxious to obtain a portion of this dog's medulla for inoculations into three or four guinea-pigs, first, because there had been several cases of rabies on Staten Island in dogs during the past eighteen months which had been demonstrated to be the cause of death by the inoculation-test and the records of which I have; and, second, the three persons bitten were in an extremely nervous state, particularly a girl of fourteen, who was bitten slightly through her sleeve, and to whom, owing to her very nervous state, I decided not to give the Pasteur preventive treatment.

I told the president of these cases, and what a bad mental state the girl was in. I said it is of the greatest moment to make the inoculations, for if I could inform this girl in eight to sixteen days that the dog had not been mad, as was quite possibly the case, it would be of the greatest advantage to her. No one can realize how a person may become demoralized after being bitten by a dog, possibly rabid, until they have seen several such cases. To all of my reasoning the only satisfaction I received was that I could have a piece of the medulla for microscopic study, but not for inoculation into animals. The scientific fact that the inoculation-test is the only one upon which in the present state of our knowledge of the pathology of the disease we can place any reliance, had no effect on the position of the president of the Society. He also said that he did not deny the existence of rabies in animals, but considered it very rare. The physician

[1] Read before the Medical Section of the New York Academy of Medicine, February 21, 1899.

who attempts to rule out certain diseases on account of their rarity soon makes a mistake, and could not in any sense of the word be called scientific. The case he is diagnosing may be the very disease he is ruling out on account of its rarity. But for a minute considering the disease rabies as rare in animals, is it justifiable to jeopardize the mental and physical welfare of these persons and take away from them the possibility of great mental comfort which would have come if the inoculation had been made with negative result, a most probable outcome? Instead of this these people will be kept in doubt as to the result of their injuries, on account of a desire on the part of the president of the society to save some pain to three or four guinea-pigs, and his own unwillingness to believe facts which scientific men all over the world uphold with one voice. The dog was autopsied six days after it had bitten the three people and three days after its death. In its heart were found 60 to 70 round worms, 7 to 10 inches long, and the report of those who made the autopsy was that they found no evidence whatever of rabies, and that in their opinion, the dog did not die of rabies, but of the worms in the heart, which was sufficient to account for its death. The gentlemen who made the autopsy certified in the daily press in an open letter from the president of the Society that these were the facts, but do not show one line of evidence that the dog did not have both rabies and the worms in the heart; two diseases have been combined in one body before now. The reason they could give no evidence in regard to the presence or absence of rabies was because there is no change so far detected sufficiently pathognomonic of the disease. If any one has found such changes sufficiently distinct on which to base a diagnosis he has kept such a fact modestly to himself.

TABLE I.—PATIENTS GIVEN PASTEUR TREATMENT FROM MARCH 5, 1898, TO MARCH 5, 1899.

No. of Patient and Age.	Date of Supposed Infection.	Location of Injury.	Cautery and How Soon.	Date of Beginning Treatment.	No. of Injections.	Dog Proved Rabid.	Result.	General Remarks.
	1898.							
1—51 years.	Feb. 7.	28 bites, both hands and arms.	None used.	Mch. 5.	24	Yes.	Death.	Arms and hands badly lacerated.
2—23 "	Feb. 7.	9 bites on arm through clothes.	Stick silver nitrate in 5 minutes.	Mch. 5.	20	"	Recovery.	Same dog as in Case 1.
3—38 "	Mch. 16.	Right thumb and hand, glove.	Silver nitrate same day.	Mch. 19.	19	"	"	Bites rather slight.
4—6 "	Mch. 16.	One bite on hand.	Silver nitrate same day.	Mch. 19.	20	"	"	Same dog as in Case 1. Injury slight.
5—38 "	Apr. 25.	Bite on forehead.	Actual, 1½ hours after.	May 21.	23	"	"	Bite half an inch long.
6—19 "	June 20.	3 bites, left leg and thigh.	Silver nitrate in ½ hour.	June 22.	12[1]	"	"	Abscess formed at seat of injection.
7—32 "	Nov. 29 to Dec. 1.	2 points on hand.	Nitric acid, 24—60 hours.	Dec. 3.	23	"	"	Treatment sent to physician in charge.
8—30 "	Nov. 29 to Dec. 1.	Hand, possibly lip.	Nitric acid, 24—60 hours.	Dec. 3.	23	"	"	Same dog as in Case 7.
9—55 "	Nov. 29 to Dec. 1.	Hand.	Nitric acid, 24—60 hours.	Dec. 3.	23	"	"	" " "
10—25 "	Nov. 29 to Dec. 1.	Hand.	Nitric acid, 24—60 hours.	Dec. 3.	23	"	"	" " "
11—14 "	Nov. 30.	Ear bitten off.	None used.	Dec. 5.	9[2]	No.	"	Mildest treatment given.
12—84 "	Dec. 2.	Hand.	None used.	Dec. 6.	15[3]	Yes.	"	
13—28 "	Dec. 10.	3 abrasions right hand.	In ½ hr., sulphuric acid, nitric acid, thoroughly.	Dec. 16.	20	"	"	Patient a veterinarian.
	1899.							
14—14 "	Feb. 4.	Severe bite on chest.	Nitrate of silver in 15 minutes.	Feb. 6.	19	No.[4]	"	No tests made.
15—35 "	Feb. 4.	3 bites on hand.	Nitrate of silver in 10 minutes.	Feb. 6.	21	No.[4]	"	Same dog as in Case 14.

[1] Patient discontinued visits.
[2] Treatment discontinued at end of two and one-half weeks as dog was proved not to have died from rabies.
[3] Patient irregular in attendance.
[4] Dog not obtained for inoculation experiments.

The president of the Society before metioned, in his letter to the public, besides printing the above-mentioned certificates which give no account of an inoculation-test with other animals, closes his letter by saying that to his mind this examination of the dog is conclusive that it did not have rabies, and if it were not for a few persons interested in the manufacture of "auto-rabic serum" (whatever that may be) and a sensational press, we would hear the cry of "mad dog" very seldom. He also says that several cases of rabies in dogs have been reported as occurring in Staten Island, but that after a careful investigation he has found the reports not to be true. As I had informed of these cases with the results

of the inoculations made by me, and as some of these dogs sent to us from Staten Island did have rabies, as clearly demonstrated by the only reliable test, the records of which I shall give later, no more need be said on the subject.

I have gone into this case at length because it only shows what obstacles have to be overcome in the work, and how difficult it is to clear the atmosphere of prejudice and unscientific arguments. I am not attempting to cry "mad dog" in all cases or anything of the kind, but I do believe in making as careful an investigation as we possibly can for the good of people in general, and when we have found in a certain locality several cases of rabies in animals I believe it is still more important to sift all matters to the bottom, and use all the means science has given us to get an unprejudiced result.

I will now proceed with the local and general treatment of persons bitten by animals. During the past year there have come to the laboratory of the Board of Health thirty-four persons for treatment. A year ago the department opened a place for the treatment of such cases of which I have been in charge since October 1, 1898. Before that time Dr. R. J. Wilson and I had charge together. In nineteen of the cases no Pasteur preventive treatment had been given for one or more of the following reasons: (*a*) The animal was evidently not mad, it being well at the time of the patient's application. (*b*) From the history of the dog it was apparent that rabies was not the cause of death. (*c*) An autopsy of the dog combined with a history of its illness made preventive treatment unnecessary. (*d*) Wounds so slight—skin hardly cut. (*e*) Slight wound through clothing.

In all cases in which cauterization was necessary and had not been properly performed it was done at the laboratory. Latterly I have used pure nitric acid; it makes a deep wound, but it has been demonstated in a large number of guinea-pigs to be very effectual. I found that nitric acid used at the end of twenty-four hours saved ninety-one per cent. of the animals treated. This percentage was much the largest one obtained. From these experiments and other observations I believe rabies to be a disease of the nervous system, that infection takes place through lacerated nerves, that the virus remains localized for about twenty four hours, and that a thorough cauterization with nitric acid would be effectual in about every case. It should be done with the patient under an anesthetic, as it is painful and in this way can be done more thoroughly. It is, of course, best to use the cautery as early as possible. The virus of rabies, as has been demonstrated by Pasteur and others, is not conveyed into the system by the blood.

I am aware that it is contrary to the present teaching to believe that late cauterization is effectual, and this fact accounts for the inefficient way many practitioners cauterize animal bites, usually with an inferior caustic like silver nitrate, which my experiments demonstrated to be of much less value than nitric acid or the actual cautery. I am not in favor of thoroughly cauterizing all bites with nitric acid, far from it; it all depends upon the circumstances attending each case. The remaining fifteen patients applying at the laboratory have been given the Pasteur preventive treatment, two of whom have just finished their course.

TABLE II.—POSITIVE TESTS MADE FOR RABIES, JANUARY 8, 1897, TO DECEMBER 13, 1898.

No. of Case.	Date of Inoculation.	First Symptoms of Rabies.	Length of Incubation Period.[1]
Dog, 1.	Jan. 8, 1897.	Rabbit, Jan. 21.	13 days.
Dog, 2.	Jan. 27, "	Rabbit, Feb. 8.	12 "
Cat, 3.	Jan. 16, "	Rabbit, Feb. 2.	17 "
Dog, 4.	Oct. 1, "	Rabbit.	8 "
Man, 5.	Feb. 2, 1898.	G. pig.	7 "
		Rabbit.	16 "
Dog, 6.	Feb. 10, "	G. pig.	7 "
		Rabbit.	14 "
Dog, 7.	Mch. 17, "	G. pig.	11 "
Dog, 8.	Apr. 25, "	Rabbit, May 14.	19 "
Dog, 9.	Apr. 30, "	Not recorded.	
Dog, 10.	June 22, "	Rabbit, July 1.	19 "
Dog, 11.	Dec. 9, "	Rabbit, Dec. 29.	20 "
Dog, 12.	Dec. 13, "	Rabbit, Dec. 31.	18 "
Dog, 13.	Dec. 2, "	G. pig, Dec. 15.	13 "
		Rabbit, Dec. 17.	15 "
Dog, 14.	Dec. 6, "	G. pig.	8 "

[1] Average for G. pigs, 9 days. Average for rabbits, 15½ days.

All the patients with the exception of the first are in good health to-day. The first and second patients (Table I.) were bitten by the same dog (Table II., dog 6) and were treated at the Health-Department laboratory. One or two other people were bitten by this dog which we found to have been rabid, and they were treated at another place. The other patients and patient No. 2 were all bitten comparatively slightly.

CASE I.—The patient, a woman aged fifty-one years, from Staten Island, was bitten February 7, 1898. The bites were of a very serious nature affecting both hands and arms, and in all numbering twenty-eight. The wounds were deep, the tissues having been severely lacerated. Judging from the pain the patient suffered there could be no question but that large nerves had been injured. No cauterization followed these lacerations, but within a short time a mild solution of carbolic was employed. The wounds bled freely. The same dog bit the people mentioned above and also a dog owned by this patient. This last dog is No. 7 in Table II. It was bitten on February 7th, and on March 17th developed rabies, was autopsied at the laboratory and inoculation-tests made with rabbits and guinea pigs, the first guinea-pig showing indications of rabies at the end of eleven days from the time of inoculation.

The patient did not believe in rabies and thought it foolish to take any treatment, but finally on March 5th, two days short of four weeks from the time of infection, she presented herself for treatment. Most of the wounds had healed but she still wore bandages and suffered considerably. The prognosis given to her family physician and her friends by Dr. Wilson and myself was very grave, for it seemed a most perfect case for an infection through the unquestionably injured nerves. The fact of there having been no cauterization and so long a delay before preventive treatment was instituted made the case to our minds almost hopeless.

Treatment was begun on March 5th and finished on the 25th. Toward the last few days of treatment the patient began to complain of intense pain in the right arm and hand over the seat of the lacerations. The pain became so severe that sleep was interfered with and anodynes were given. On the day the patient was to have received her last treatment she was taken ill, forty-seven days after having been bitten. Her family physician did not believe in hydrophobia, so that at the beginning a diagnosis of probable grip was made. The signs and symptoms as they developed were as follow: Increased pain in right hand, arm, and shoulder, and during the night of March 25th she had frequent attacks of vomiting; when seen by her family physician on the following day, pain in arm and shoulder was less but she felt very ill; she was lying in bed and complained much of weakness and very painful vomiting. The right arm was of a rather dusky color, the wounds dark red and painful when touched. At this time there was no paresis of any kind; her grip was perhaps slightly weaker, but not noticeably so, her throat was reddened, and she had a slight coryza. A spoon was put on her tongue and no difficulty in swallowing was noticed at this time. Her pulse was rapid, 116, and its rhythm irregular; temperature 100° to 101° F. On the next day, March 26th, when seen in the morning she was very nervous, had slept but little, and now complained of inability to swallow. She had taken no form of nourishment since 4 P.M. of the day before as she said it brought on the spasms. The physician attempted to look down her throat, but the mere appearance of the spoon precipitated a spasm of the diaphragm. She jumped up and begged to be patted on the back and said she could not breathe. After being quieted a good view of her throat was obtained without the aid of a spoon. The tongue was protruded naturally. Her right arm hung down by her side, tired, she said, and she could not raise it without the help of the left hand. When supported she could lift it but the grip was feeble. During the day she had many of these attacks, jumping up and leaning for support on one of the attendants, with a slight rotation of the body to the right and backward, at the same time suffering fearful agony. She became steadily weaker during the day, the spasms became more frequent, and from less apparent cause. There was wrist-drop, and if the right arm were suddenly unsupported a spasm would follow. The spasms grew more severe, involving the whole body, and when seen by Dr. Wilson and myself on the afternoon of the 26th the scene was one never to be forgotten. There was well-marked paresis of the right arm which felt cold and was much congested. The spinal nerves became involved so that at times she became rigid, only touching her head and heels to the floor. She retained consciousness all through her illness. The suffering and feeling of apprehension was awful to behold. During the night of the 26th she became gradually weaker, some increased salivation was noticed, and she died of exhaustion on the morning of the 27th at 5 o'clock. At no time did she bark or make any attempt to bite, but was constantly crying out for relief in some form from her terrible distress. This is the only case of hydrophobia I have ever seen.

No autopsy was made, but we have enough evidence to prove it to have been a true case of hydrophobia. To forestall any possible inquiries from those who may say that the patient became infected by the treatment, I will say that:

First, we proved the dog rabid which bit this woman, also a dog was proven mad which was bitten by this dog on the same day, and which died ten days before this patient.

Second, we treated another patient at the same time and with the emulsion of cord that the patient who died received.

Third, the period between the time when any material given by us was at all virulent was only two weeks before the patient developed the disease.

Fourth, the fact that no cautery was used and that preventive treatment was not begun for nearly four weeks.

Fifth, the fact that the symptoms began in the sites of the wounds made by the dog in the right arm gradually causing paralysis of that member. If animals are inoculated in a nerve of an extremity the disease begins as a rule as paralysis in the extremity. This point has been proven by Pasteur and corroborated by others, among them myself.

Sixth, two rabbits were treated at the same time and both remained well.

Seventh, in several thousand cases treated by preventive method in the Pasteur Institute, Paris, no serious results have ever been produced by Pasteur treatment.

CASE II.—In Table II. material numbered five was taken from a man who died of rabies in Morristown, N. J., the patient of Dr. James Douglas. J. C., was bitten by his own dog on November 3, 1897. The dog was immediately killed so no evidence was obtained from that source, nor do we need any in the light of subsequent developments. The bite was on the thumb, and was cauterized with silver nitrate in three days. The man worried a little but not much more was thought about the case till January

26, 1898, about eleven weeks after the injury. The family physician was called in and found the patient sitting up in bed. He was very nervous and restless, and complained of great difficulty in breathing. Pulse, 120; temperature, 101.2° F. The patient called for a cup of coffee, but when it was brought to him he became very much excited and was trembling all over. He took the cup in his hand and after a great effort succeeded in getting a part of the coffee in his mouth the rest spilling on his face. He then had a severe paroxysm of the muscles of respiration and deglutition. His speech was slow and labored. He was apprehensive but felt encouraged when reminded that the dog could not have been mad. He was unable to sleep and was very thirsty. Water did not trouble him except when he tried to swallow it. He had no frothing at the mouth, but was troubled with a good deal of saliva, which while he lay on his side would run out of his mouth. The next morning all his symptoms were more severe; his pulse was 120 and temperature 101.6° F. He was unable to urinate. In the afternoon he was about the same. The next day he was seen at 4 A.M. He was sitting up in bed in great mental distress, and with an expression of intense anxiety. He begged to be saved. His paroxysms were very severe. He had not slept any during the night. He complained of great weakness, also of great thirst; thick mucus kept coming from his mouth. In the afternoon he was in a mild delirium. His mind, however, soon cleared and he was perfectly rational. This condition continued — occasionally delirious, then rational, gradually growing weaker, and he finally died from exhaustion on the 30th, after four days of fearful suffering. He never barked nor made any attempt to bite or injure anyone. His thirst was fearful, but he could not bear anything in his mouth on account of the spasms.

An autopsy was made by Dr. Thomas P. Prout, pathologist to the State Hospital, Morris Plains, N. J. The only gross lesion found of the central nervous system was a congestion, especially marked in the pons, medulla, and spinal cord, but by no means confined to these organs. The cortical cells of the brain under the microscope showed an extensive vacuolation, absence of chromatin in many instances, and the loss of the nucleus, together with an extremely granular condition of many cells and an irregularly outlined nucleus. Lungs showed some hypostatic congestion posteriorly with some bronchial congestion. Crepitation diminished in both, but especially on the right side. Spleen of normal size and appearance. Heart muscle very flabby; all valves normal. There was an ante-mortem clot in the right auricle, extending down into the right ventricle, and up through the pulmonary orifice. Microscopic examination of the kidneys showed some swelling of the epithelium in the convoluted tubules, and the cells in some portions were granular and necrotic. The vessels were somewhat engorged.

An examination of the blood was made, the patient not having taken food for about four hours previously. The differential count gave evidence of a decided leucocytosis, and was as follows: Lymphocytes, 7.4 per cent.; large lymphocytes, 6.4 per cent.; multinuclear leucocytes, 86.2 per cent.; eosinophiles, none. In order to make a positive diagnosis a portion of the brain was sent to the New York City Bacteriological Laboratory, and resulted as is seen in Table II., No. 5, the first guinea-pig developing furious rabies on the seventh day, and the first rabbit developing paralytic rabies on the fourteenth day after inoculation. From these animals other animals were inoculated with positive results.

Case III.—Mrs. E. of Malden, Mass., thirty years old, on November 13, 1898, was bitten on the face by a suspicious dog. About fifteen stitches were taken in the wound, which had previously been washed well with mercuric-bichlorid solution 1 to 4000. She died December 27th. Four or five days before her death she became very nervous, her face was flushed, and she complained of difficulty in swallowing on account of spasms, but she was able to take a little medicine. These symptoms became aggravated, the pulse gradually grew weaker, and she died at the end of four or five days. She was seen by Dr. Harlow and Dr. Oddin of Malden and a nervous specialist from Boston, who diagnosed the case as one of hydrophobia. Dr. R. H. Fitz of Boston was also called in consultation, and he confirmed this diagnosis. No autopsy. The dog which bit this woman was known to have bitten several dogs, one of them, a bull-terrier, being badly bitten on the head, a large lacerated wound; the dog at the end of eight days developed typical furious rabies,—spasms, inability to swallow, and increased salivation, and died in five days.

The veterinarian, Dr. William M. Simpson of Malden, who had this dog in charge, and who kindly sent me the history of Mrs. E., was afraid he had been inoculated by the dog through a wound on his hand, and came to New York for treatment. He is now in perfect health. The fact that this last dog developed rabies eight days from the time of the severe bite makes the inoculation period shorter than is usually the case. The case was too typical, however, to be mistaken, and in my opinion completely confirms the diagnosis made in the case of Mrs. E.

Case IV.—Dr. Edward N. Sparks of Prince's Bay, Staten Island, sent me the following history: Mr. T. S., aged sixty years, of Staten Island, was bitten December 23, 1898, by his dog on the right cheek, which was badly lacerated, making a wound two and one-half inches long. The wound was washed out with weak carbolic-acid solution, and Dr. W. M. Eagan was then called who cauterized the wound with nitric acid. The wound healed to some extent, so that before death there was only a deep red cicatrix. No examination was made of the dog, which was at once killed. The patient, a carpenter, went about his work and felt no ill effect

until January 27, 1899, when he began to complain of pains all over the body and a smarting sensation in the wound in his face; this was just five weeks after the infection. The next day the patient was much depressed, would start up at the least noise, and showed marked morbid aversion to all kinds of liquids. He could swallow, however, and took a little solid food and some milk. The next day, January 29th, the patient was seen at 9 P.M. He was found lying on a sofa, perfectly rational, but unable to keep still in one position. Some jelly was given to him, which he swallowed with great difficulty. The edges of the wound were of a deep, ugly, red, but he said there was no pain in it. His pulse was 86, strong but slightly intermittent, tongue and throat very dry, and covered with white viscid mucus. He was not delirious, and was able to talk, although his articulation was thick, and it evidently gave him much pain. The next day, at 8 A.M., the 30th, the patient was about the same, but pulse was weaker, 110, and slightly irregular. At 2.30 he died in a paroxysm, three days after the first symptoms. Unfortunately, there was no autopsy.

These four cases resemble each other in many respects. In the first three cases there is proof enough to convince most of us that the patients died from the bites of dogs, and the fourth resembles the first three cases in all essential points, and undoubtedly it was the same disease in all four people.

To compare them: First, all bitten by a dog, in three of the cases very severely; second, time between infection and first symptoms was five to eleven weeks; third, time between first symptoms and death three to five days; fourth, all the patients had distinct spasms, increased by irritation of any kind; fifth, difficulty in swallowing most prominent symptom; sixth, in three cases increased flow of saliva; in fourth case this point was not noted in history sent to me; seventh, increased rate of pulse, which gradually became weaker; eighth, mind clear most of the time; ninth, none of the patients showed any tendency to bark or bite, but fully realized their terrible condition.

Whether we call this disease hydrophobia or give it some other name makes little difference. We have a distinct disease with fairly definite symptoms. That the disease was inoculated by means of bites of animals suffering from the same disease is evident. These cases all occurred during the past year.

The Pasteur preventive treatment was given to 1308 people at the Pasteur Institute of Paris from January 1, 1896, to January 1, 1897. These people had all been bitten by suspicious animals. A mortality-rate following this treatment of 3/10 of one per cent. was shown of patients dying of rabies. In looking over statistics of rabies in Germany, Austria, and England, a death-rate of fifteen per cent. of undoubted cases developing rabies, after bites where no preventive treatment was given, would be a conservative estimate.

In treating a patient bitten by an animal, I should proceed about as follows: Obtain the history of the animal as far as possible. If the locality where the patient was bitten had been the seat of other cases recently, and the wound was in an exposed part of the body, hand or head, I should cauterize thoroughly within twenty four hours, using an anesthetic and nitric acid. If the wounds were severe give Pasteur preventive treatment, if the bite was superficial or through the clothes, and the cauterization was made thoroughly within twenty-four hours, I should probably do no more; certainly not if there had been no cases of rabies in the neighborhood.

The Pasteur preventive treatment can never do harm and if the patient desires it, I should always advise its use. It is given in the following way: The spinal cord of a rabbit dead from laboratory rabies is hung in a sterile jar with two vents, one in the lower and the other in the upper part, both filled with absorbent cotton. In the bottom of the jar is placed a few sticks of caustic potash to aid the drying process. The jar is kept in a dark room at a temperature of 68°–72° F. A portion of the cord thus prepared is emulsified by the gradual addition of sterile water and by means of a glass rod. A cord dried fourteen days is the one used for the first injection and then each day a fresher cord is employed until one dried only three days is finally used. The dose of the emulsion for the older cords is 3 c.c. for adults, and then finally, 1½ c.c. for the fresher ones. The injections should be given under aseptic precautions either into the subcutaneous tissue of the abdominal wall or the buttock, care being taken not to penentrate the muscular tissue. No particular reaction, either local or general, should follow the injections. Before the cord is emulsified at least two tests should be made to prove its freedom from any chance contamination. The usual course of treatment lasts fifteen days in which time twenty to twenty-five injections are given. If the subject comes late or if the injury is very severe and near a large nerve, the intensive form of treatment may be employed. In this way more injections are given daily, thus rapidly approaching the time to use virulent cords. Children bear nearly as large doses of the cords as adults.

The disposition of animals which have bitten people I believe should be as follows: Never killed, but captured, and placed in a kennel under lock and key for a week. If at the end of that time they are well, there is naturally no danger for the person

bitten. If the animal dies, an autopsy should be made, all the organs examined, and a portion of the brain and spinal cord emulsified and inoculated into guinea-pigs and rabbits. If a disease which could cause death should be found in other organs it is of importance, but we should also make the inoculation-tests to demonstrate beyond a doubt that rabies was not also present in the same case. We would in this way be able to say truthfully that according to the result of the autopsy and tests, the animal did or did not have rabies.

The shooting of the offending animal is a common mistake but is a most serious one and should be protested against by all intelligent people until we hear no more of a barbarous and ignorant mistake which has been made and is still made so frequently. In this way, many harmless animals are killed which are perfectly free from rabies, and persons who have been bitten are left in terrible doubt as to the condition of the animal.

That rabies is a relatively frequent disease in animals, I have no doubt. Dr. R. S. Huidekoper, at a recent meeting of the Harvard Medical Society where I read a paper on hydrophobia, soon to be published in *The Journal of Experimental Medicine*, gave some very interesting figures of the prevalence of hydrophobia in animals. He believes, as do many others, that rabies is more frequently seen in its paralytic or dumb form than in the furious excited type in which animals are more inclined to bite. This paralytic form is often mistaken for other diseases, and unless inoculation-tests are made, the case is recorded as something else. Dr. Huidekoper has seen about two-hundred cases of hydrophobia in the different domestic animals, both in Europe and in this country, many of the cases proven by inoculation-tests. The longest incubation period he has observed was six months in a hound in Belgium, proven by inoculation-tests. A committee not long ago was formed, among them Dr. Huidekoper, to find out if possible how much rabies prevailed in this country, and in what particular places. To do this, veterinarians all over the country were written to, and from their answers a chart of the country was made, giving the different localities with the number of cases of rabid animals seen there for a certain number of years. Perhaps a whole State would have hardly a case and again in a certain part of a State there would be a great many cases while none in the rest of its area. In the West many cases occurred in the domestic skunk and it has been so prevalent and so dangerous that in one of the States the legislature has taken up the matter for consideration with a view to taking radical measures.

Dogs are the most common animals in this part of the country to suffer from rabies. Fortunately people are not particularly susceptible so that they are seldom infected though frequently bitten. We will have rabies so long as dogs are allowed to run around without an owner or without supervision of some kind. People themselves cannot be trusted to destroy dogs for they do it cruelly. It seems to me the way to eradicate rabies from civilized centers (I am referring to rabies in dogs) would be to have intelligent agents appointed to do nothing else but look out and see that all dogs are licensed, to put a high license on dogs, higher on female than on male dogs; for these men to see that every dog has an owner; and any dog not looked after closely should be taken and disposed of humanely. In case of a suspected outbreak of rabies, to have an expert on the subject detailed to study the cases, to have all dogs in that place muzzled or taken on a leash or both for a period of six months from the time of the outbreak, and all dogs found loose, destroyed during the same period. To do this, there should be employed a number of well-paid, intelligent men. In this way I believe we could largely control this disease, and we would indeed then hear little of the cry of mad dog. A law in Germany making muzzling of dogs compulsory has been very effectual in controlling rabies.

To demonstrate further the point that rabies is not such a very uncommon disease in animals, I will give a few statistics on the subject. My friend, Dr. Langdon Frothingham of Boston, has been examining animals sent to him as pathologist to the Massachusetts Cattle Commission. He has examined thirty animals supposed to have died from rabies in and around Boston during the past eighteen months. He has used the inoculation-tests with rabbits, and among these thirty animals twenty have been proven to have died of rabies. Among these animals was a horse and a cow. The average time between inoculation and beginning rabies in the test rabbits was sixteen days, nearly the same average that we obtained in the rabbits in Table II. In 14 cases out of 21 examined by us, guinea-pigs gave an average number of 9 days between inoculation and beginning rabies, as given in Table II. I began to use guinea-pigs about a year ago, and the average time in developing rabies shows a gain of about a week in the case of the guinea-pig over the rabbit. Guinea-pigs are also much less likely to die of septicemia, points of considerable importance when a person is perhaps waiting for a diagnosis of the suspected animal before beginning preventive treatment.

Dr. J. H. McNeall of the Veterinarian Hospital, University of Pennsylvania, who was a patient at the laboratory in New York, and received the

Pasteur preventive treatment from me last December, writes that from June 1, 1898, to January 1, 1899, a period of eight months, 360 cases of all diseases in animals were treated in the hospital. Twelve of them were diagnosed as rabies, and six of them were true cases, as proven with rabbits by test-inoculations.

Dr. W. M. Simpson, a veterinarian of Malden, Mass., who came on here for treatment, and who gave me the history of Case IV. of hydrophobia in Mrs. E., which I have already described, has seen twenty-two cases of rabies in animals and the paralytic form most frequently. In nearly all cases the diagnosis has been confirmed by inoculation-tests. The symptoms presented as a rule are abundant flow of saliva, more or less vomiting and uneasiness which gives place to the characteristic condition of paralyzed jaw and throat. The dogs will often be able to lap water for a few minutes, although unable to drink, but will keep returning and trying to again and again. The dogs with the paralytic form will not, as a rule, bite, but will act as if there were a bone in the throat. The peculiar high-pitched howl is most characteristic.

Eight cases of suspected rabies in dogs have been sent to the laboratory from Staten Island during the past year, and in six of the animals the inoculation-tests were positive, showing that there has been a certain amount of reason for the recent mad-dog scare.

Dr. Harold C. Ernst, Professor of Bacteriology at Harvard, not being able to accept an invitation to attend this meeting, says that, in his opinion, rabies is not very frequent in man, that the number of cases of the disease seems to vary very much in different years, that the cauterization of bites does no good unless done practically instantaneously, but that sucking the wound and ligation when practicable should be practised. He says further that he knows of no way by which the diagnosis can with certainty be made except by the inoculation-test.

Dr. William H. Welch of Johns Hopkins Hospital, Baltimore, says in a letter to me of recent date: "I believe that rabies is more prevalent in this country than is generally supposed. It cannot be called uncommon in animals in this State, and several authentic instances have occurred in human beings. Before the establishment of the Pasteur Institute in connection with the College of Physicians and Surgeons of Baltimore I noted the greater number of suspected rabid dogs which had bitten persons in this vicinity, and during about five years twelve of these dogs were proven experimentally to be rabid. I think that most cases diagnosed as rabies by competent physicians are in fact rabies. We have means of recognizing the existence of rabies as precise and conclusive as recognizing typhoid fever; that is, the inoculation of rabbits in series. As regards rabies in animals in this State I would refer you to a paper by Dr. Clement, our State Veterinarian in the *Proceedings of the Maryland State Veterinary Association*, p. 177, for 1897. In the same proceedings for 1898, p. 28, are further statements about the prevalence of rabies elsewhere. For Washington see *Twelfth and Thirteenth Annual Reports of the Bureau of Animal Industry* (1895–96), p. 267. We greatly need accurate information as to the prevalence and distribution of rabies in this country."

Dr. Leonard Pearson, Dean of the Veterinary School of the University of Pennsylvania, writes to me as follows on the subject of rabies: "This disease is one that I have had considerable experience with during the last three years. There have been several extensive outbreaks in Pennsylvania. During the year 1898 I obtained authentic reports of the death from rabies in Philadelphia of 3 men, 1 boy, 55 dogs, 3 horses, 6 cattle, 4 pigs, 1 goat, and 10 sheep. Many other alleged cases have been reported but not proven.

"This list does not include the animals that were killed on account of fear that they might develop rabies. It includes only those actually developing the disease. In many instances the diagnosis was confirmed by the inoculation of rabbits. In several instances I have been able to trace an outbreak through several generations of disease. It is unfortunate that this disease is so poorly understood by the laity and by many physicians.

"The conflicting views that prevail in regard to it make administrative procedures extremely difficult.

"I hope that the Section on Medicine of the Academy of Medicine will succeed in placing this important subject in such a light that many false views will be obliterated."

I have heard from many prominent medical men recently and I find none who has doubts as to the existence of rabies in man and animals.

The representative men abroad and in this country, those who do the principal thinking and teaching, recognize the importance of the subject. Owing to rabies being a rare disease in man there is still a great deal to be learned about its various manifestations and methods to be pursued to eradicate it from civilized centers.

Smallpox Epidemic in Texas.—The smallpox epidemic in Texas is very serious. There are over 200 cases in Laredo, and the epidemic has spread to nearly all the towns in Central Texas.

THE CAUTERIZATION OF WOUNDS INFECTED WITH THE VIRUS OF RABIES, AFTER AN INTERVAL OF TWENTY-FOUR HOURS.[1]

BY FOLLEN CABOT, M.D.,
OF NEW YORK;
ASSISTANT BACTERIOLOGIST TO THE NEW YORK CITY DEPARTMENT OF HEALTH.

DURING the past six months I have been conducting a series of experiments with guinea-pigs to determine the effect of different cauteries on wounds after an interval of twenty-four hours from the time of infection by rabies. It has been commonly believed that unless a cautery is used within an hour after infection by a suspected animal it would be useless. This belief is held by physicians in general, and also, apparently, so far as the literature seen by me indicates, by those familiar with rabies. For this reason physicians when applying a cautery later than an hour after infection do so largely as a matter of form, for its moral effect on the patient, and so the application is not thorough, and in consequence not effectual. There is no evidence to show that this is the case at all; no systematic investigations have been published to prove the point one way or the other.

We know that the virus of rabies is not carried into the system by the blood, but through the nervous system. The objects of the series of experiments undertaken by me, the results of which are given in the tables below, were: First, to demonstrate if it be possible that the disease, rabies, after an interval of twenty-four hours has elapsed between the infection and cauterization, can be prevented from subsequently developing; and, second, to demonstrate the comparative values of some of the different cauteries and simple cleansing of the wound.

In the experiments I have used 287 guinea-pigs. The first 79 were employed to demonstrate at what point inoculations of virus would be most fatal where a cautery could be safely used, whether near a large nerve or not, and in what form and dose to employ the rabic virus. After much careful study of the subject with these seventy-nine animals, the following method was employed in all the experiments tabulated below: A portion of medulla taken from a rabbit dead from laboratory rabies was beaten into an emulsion composed of one part of medulla to five parts of sterile water. Of this emulsion one cubic centimeter was injected with a hypodermic needle into the outer and upper part of the thigh of a guinea-pig. The hair was closely cut, and the point of the needle introduced one-fourth of an inch, at right angles, into the region of the sciatic nerve. This injected virus was left undisturbed for twenty-four hours, at the end of which time an incision half an inch long was made over the seat of puncture, exposing the nerve. The tissue in the wound surrounding the point of puncture was carefully swabbed out and the cautery applied, the anima meantime being anesthetized with chloroform

The first cautery employed was fuming nitric acid, and the results are given in Table No. I.

TABLE NO. 1.—NITRIC ACID.

No. of Series.	No. of Animals Injected.	No. of Animals Cauterized.	Per Cent. Lived.	Not Cauterized.	Per Cent. Lived.
1	8	4	100	4	00
2	13	8	75	5	20
3	6	3	100	3	00
4	12	6	83	6	17
5	21	13	100	8	38
Totals.	60	34	91	26	15

This demonstrates that when nitric acid was used on infected wounds after an interval of twenty-four hours, ninety-one per cent. of the animals did not develop rabies.

TABLE NO. 2.—ACTUAL CAUTERY.

No. of Series.	No. of Animals Injected.	No. of Animals Cauterized.	Per cent. Lived.	Not Cauterized.	Per cent. Lived.
1	11	7	85	4	25
2	20	15	60	5	20
3	14	11	72	3	00
4	14	11	63	3	00
Totals.	59	44	70	15	11

In Table No. 2, in which is shown the results when the actual cautery was employed after the same interval between infection and cauterization, as in Table No. 1, seventy per cent. of the cauterized animals lived, twenty-one per cent. less than when nitric acid was used. Undoubtedly the heat killed all the virus with which it came in contact, but it is very much more difficult to reach all parts

TABLE NO. 3.—NITRATE OF SILVER. (LUNAR CAUSTIC.)

Series of Animals.	No. of Animals Injected.	No. of Animals Cauterized.	Per Cent. Lived.	Not Cauterized.	Per Cent. Lived.
1	18	15	46	3	00
2	12	9	88	3	00
3	15	13	31	2	50
Totals.	45	37	55	8	16

[1] Read before the New York Pathological Society, December 14, 1898.

of a wound with the cautery-needle than with a fluid like nitric acid, which naturally seeks a level, and thus penetrates all portions of the wound.

According to Table No. 3 it will be seen that only a little more than one-half of the cauterized animals did not develop rabies. In these experiments nitrate of silver was demonstrated to be inferior to nitric acid or the actual cautery.

In the next series of experiments, the results of which are presented in Table No. 4, no cautery whatever was employed, but at the end of twenty-four hours after injection in the usual way the point of infection was cut open, and the wound swabbed out with dry absorbent cotton and then left open.

TABLE NO. 4.—WOUNDS SIMPLY SWABBED OUT.

No. of Series.	No. of Animals Injected.	Number Swabbed Out.	Per Cent. Lived.	Not Swabbed Out.	Per Cent. Lived.
1	23	15	33	8	12
2	26	11	29	10	20
Totals.	49	26	31	18	16

The results shown by this table (No. 4) seem to demonstrate that a certain amount of good may be derived from simply opening and swabbing out infected wounds.

In the foregoing tables all the animals that died had typical rabies. There was a question of this in five animals, and these have not been included in my statistics.

It seems to me that the following observations on the result of my experimental investigations in hydrophobia are of sufficient importance to be recorded: That guinea-pigs inoculated subdurally with street rabies develop the disease as a rule in its furious form in from seven to ten days, and are much less likely to die from septicemia, while rabbits treated in the same way do not as a rule develop the disease until fifteen to eighteen days have elapsed, and then in the paralytic form, and are also very susceptible to septicemia, thus proving the superiority of the guinea-pig for the purpose of making an early diagnosis in the case of a suspected animal. This is a point of considerable importance when it is remembered that most of the subjects one sees have been bitten by animals when the diagnosis of rabies is questionable, an exact diagnosis being of the utmost importance on account of the subsequent treatment.

The following case is an example, and several such have come under my personal observation: A person was bitten by a suspicious animal; the animal was killed and inoculations were made from the medulla into rabbits and guinea-pigs; at the end of ten days the animals remained well, so the Pasteur treatment, which had been employed in its mildest form, was not increased, but was continued a few days longer as a precautionary measure, and then, as the animals still remained well, discontinued altogether.

It will be well, however, to bear in mind the individual immunity or delayed development of rabies in a small percentage of guinea-pigs, and to inoculate a sufficient number of animals to allow for such an individual resistance to the disease. In the light of the history of a recent case, in order to assure an early diagnosis, I shall in future inoculate from fifteen to twenty guinea-pigs from every suspected subject.

An animal supposed to he mad should never be killed, but should be confined and carefully watched during at least two weeks; if it dies before that time a definite knowledge of the course of its disease will be gained, and the medulla may be used for inoculations, while if it remain well for two weeks fear of hydrophobia need no longer be entertained, with the consequent elimination of the element of danger to the patient and his great mental relief.

The foregoing observations have been of practical use during the past ten months, during which time the Health Department, having adopted the Pasteur preventive treatment for hydrophobia, has treated several people and has examined many animals which were sent to the laboratory for autopsy and test-inoculations to determine whether or not the case was one of rabies.

The conclusions I have drawn from my investigations are: (1) That ninety-one per cent. of guinea-pigs can be prevented from developing rabies if the wounds be cauterized with chemically pure nitric acid at the end of twenty four hours from the time of infection, probably a larger percentage if the cautery be used earlier. (2) That fuming nitric acid is more effectual than the actual cautery or pure nitrate of silver. (3) That some degree of benefit is derived from thoroughly opening and swabbing out an infected wound within twenty-four hours from the time of infection when no cautery is used. (4) That in cases in which the Pasteur treatment cannot be applied great benefit may be derived from the correct use of the best cautery and proper treatment of the wound. Even in cases in which the Pasteur treatment can be given, an early cauterization will be of great assistance as a routine practice, and should be very valuable, as the Pasteur treatment is frequently delayed several days for obvious reasons. (5) That in the case of small wounds all the treat-

ment probably indicated will be thorough cauterization with nitric acid within twenty-four hours from the time of infection. (6) That from twelve to sixteen per cent. of the guinea-pigs used as controls do not die after inoculation, thus demonstrating that a small percentage of guinea-pigs have a natural immunity from rabies.

THE RELATION OF DIAGNOSIS AND PROGNOSIS IN HIGH GRADES OF GASTRIC STAGNATION.

By A. L. BENEDICT, M.D.,
OF BUFFALO, N. Y.;
PROFESSOR OF PHYSIOLOGY AND DIGESTIVE DISEASES, DENTAL DEPARTMENT, UNIVERSITY OF BUFFALO.

In cases of marked dilatation, and even in milder degrees which show severe symptoms, or in which advancing age or some similar circumstance arouses grave suspicions as to the nature of the disease, mechanical, chemical, and vital elements must all be considered in making a prognosis. Three questions present themselves: (1) To what degree can the size of the stomach be diminished and its motor-function be restored? (2) Will the stomach regain its digestive power? (3) Is the life of the patient threatened? At first thought it would seem that the first question would not occur to the patient, but, in a surprisingly large number of instances the patient is aware of the degree of dilatation, can map out his own stomach quite accurately, and may even be an adept in the use of the tube.

Mr. W., aged thirty-five years, in comfortable circumstances, gave a history of stagnation extending back thirteen years, without obvious cause, though ulcer at the pylorus was suspected. For four years he had used the stomach-tube, mainly without medical supervision. His stomach, nine hours after a meal, and further emptied by repeated vomiting, extended fully an inch to the right of the median line and as far below the umbilical equator. It was as large as a full stomach should be and an inch and a half below the normal position. The diagnosis between sagging due to dilatation and sagging due to ptosis was somewhat doubtful. For some reason not noted the diaphane was not used to decide this point though the writer would confess that he cannot depend absolutely on this method of discrimination. In fact true dilatation is very likely to accompany displacement of the stomach while apparent ptosis is always noted in dilatation unless advanced pregnancy or some peculiar condition keeps the stomach at a high level. Granting that the trouble was genuine dilatation this case represented about the maximum degree in which cure can be expected by medical treatment. The first question in prognosis was, therefore, doubly in doubt; the duration of the trouble and the fact that the patient was still able to attend to his business made the third question as to maintenance of life favorable. The second question, as to the probability of cure of dyspeptic symptoms in case the stomach could be restored to normal size, was answered only by the progress of the case, and then not positively. Hydrochloric acid was found present several times about four hours after eating, but was absent an hour after a test-meal. The filtered gastric juice on adding hydrochloric acid digested coagulated egg-albumen fairly well. Sometimes it was necessary to supplement the secretion of hydrochloric acid, sometimes not. On the whole it was decided, especially as after a month the stomach had contracted and risen very nearly to its normal location, that thorough treatment would bring about a cure unless there remained so great a mechanical obstacle at the pylorus that the dilatation would tend to recur as soon as treatment should be stopped. The patient proved to be one of the kind that is not lacking in appreciation but that does not persist in treatment. He was materially improved and even as late as five months after the beginning of treatment and more than three months after its cessation his stomach was in fair position though showing some relapse. Naturally the dyspeptic symptoms had not entirely disappeared.

This case is reported rather fully because it stands as a type of a fairly large number. Judging from other cases which have been under observation for a much longer period, if such a stomach can be reduced to its normal size, if cancer can be eliminated from the diagnosis, if there is not a cicatrix or other lesion at the pylorus which tends to reproduce the dilatation, if the ferments are present in the gastric juice, if there is no renal nor circulatory trouble to maintain a catarrh of the stomach, if the patient will continue treatment for six months and will abstain from positively harmful articles of food and drink, he can expect to be cured symptomatically—that is, functionally—as well as in regard to gastric area. In the present case, as in one of the milder cases elsewhere reported,[1] there was some indication of beginning sclerosis of the liver. In the case of another patient whose stomach was of about the same size and who has considered himself cured for two years hepatic contraction certainly exists and just as certainly will, sometime, reassert itself by a renewal of gastric symptoms. But in a surprising number of cases all of the conditions necessary to a cure will be fulfilled.

The prognosis as to the chemic restoration of the stomach must, nevertheless, be guarded. In cases of curable dilatation of marked degree the patient should understand at the beginning of treatment that a "dyspepsia" will persist for several months after the size of the stomach has been reduced to normal, if such a restoration be possible. If the muscular tone of the organ becomes normal so that it is empty at the proper time after a meal, if hydrochloric acid is present in normal amount and the filtered juice

[1] Medical News, April 9, 1898.

acts rapidly on coagulated egg-albumen, if gastric mucus—which is quite easily distinguished from esophageal—is not abundant, the prognosis is favorable. The microscopic examination of particles of mucous membrane found in the wash-water after lavage has been described by Ewald, Einhorn, Hemmeter, and others. These examinations are tedious and by no means as reliable as might be anticipated. Careful studies of the stomach have shown that the mucous membrane does not necessarily show the same conditions at different points. It is therefore a matter of accident whether a bit of exfoliated epithelium gives us a fair average or an exceptional picture of the state of the stomach. Einhorn's and Hemmeter's reports show also that there is only a very general correspondence between the chemic state of the glands and the microscopic findings. There is also a practical consideration which would naturally occur to any one *a priori* but which is verified by clinical experience, namely, that it is difficult to base a definite opinion as to diagnosis on a shred of tissue which is in nine cases out of ten, merely dead epithelium cast off from the mucous membrane. Hemmeter mentions an instructive case in which a student tore off a little piece of gastric mucosa, and Turck has devised an instrument for thus sampling the mucosa of dogs, but it is never justifiable to seek a fresh piece of tissue from the stomach of a patient. It is evident to any one who will look at the figures of cancer-nests and of normal alveoli as shown in text-books—Ewald's for instance—that slight degenerative changes after exfoliation will often obscure the differential diagnosis. In a case seen by the writer, in which several competent physicians had diagnosed cancer and in which a pyloric tumor was palpable, which was also marked by hematemesis, five examinations failed to reveal a typical cancer-nest, though many round epithelial cells were seen. In another case it was possible to state quite positively that cancer-nests were present though no one group of cells would justify an absolute statement, but the value of the microscopic examination was vitiated by the fact that other signs and symptoms made the diagnosis still more positive. However, in many cases of suspected cancer every possible diagnostic light is needed. Thus, in general, the writer would grant a microscopic examination of fragments of gastric mucosa ought to be made in every doubtful case, but rather with the idea of training the diagnostic faculties than because definite results are at present attainable. The main value of such study is in the distinction of cancer. Up to the present time this method has not enabled us to distinguish accurately between organic and functional diseases of the stomach so that the differentiation between catarrh and glandular sluggishness remains a vague one.

The vital question in prognosis refers to the coincident development of some disease more malign in its tendencies than the dilatation or other degree of muscular change. Extrinsic diseases, as of the heart and kidney, which are very frequently the indirect cause of gastric catarrh and dilatation, need not be considered in detail. The three grave gastric diseases are anadenia,—which may be considered the culmination of catarrh—ulcer, and cancer. Anadenia is fatal only when deficient motor-power of the stomach or serious failure of the intestinal digestion occurs. As a general rule the intestine will maintain good nutrition so long as the stomach will push its contents along. It is not possible to make a positive diagnosis of anadenia during life unless through surgical opportunities for direct investigation, but the condition may be inferred with great probability if several examinations of the gastric contents show non-acidity (hydrochloric) and absence of pepsin. Addison's disease may manifest itself by a suppression of ferments simulating genuine glandular atrophy.

The diagnosis of frank gastric ulcer is easy. Latent ulcer, according to researches by Stoll and others in Germany, seems to be of an entirely different clinical nature, usually affecting the middle-aged and elderly, not prone to hemorrhages of any magnitude, and not diagnosable during life, unless with the gastroscope. A case showing by external examination almost the same gastric area as in the first case reported has been under observation since 1891 and the history shows that the dilatation was then of some years' standing. Repeated hemorrhages occurred. When a patient consults a physician regarding prognosis his inquiries are generally, in substance, Can I get well? and How long shall I live? In the case of ulcer we can no more answer these questions than similar questions by a man sitting on a keg of dynamite; we can only say that the condition is always dangerous but that the fatal accident may be averted.

The most important question regarding prognosis in gastroptosis and dilatation is only another wording of the question as to the presence or absence of malignant disease. The solution of the problem is easy and the prognosis correspondingly grave when cachexia, tumor, and hemorrhage, one or all, are marked. Sometimes the exfoliation of parts of a growth renders the diagnosis as indisputable as one made on the autopsy-table. But such a diagnosis and prognosis are hopelessly late. Realizing this, the profession has caught at every straw that might support an early diagnosis and has not stopped to consider that while cancer almost always leads to

serious depression of function the same degree of depression may exist temporarily without cancer. Diminution of urea, absence of hydrochloric acid, presence of marked lactic-acid fermentation have in turn been upheld as pathognomonic of cancer. All have likewise been disproved, though the German investigations referred to in several reports of the meetings of the Berlin Medical Society for 1895–6 regarding the fallibility of the lactic-acid test have only recently become known in this country. It is surprising that the presence or absence of pepsin, which is really more serviceable in the diagnosis between malignant and non-malignant gastric failure than any of the others, has not been suggested as a pathognomonic sign. But non-malignant anadenia shows a lack of ferments. However, from the patient's standpoint, a complete anadenia with concomitant intestinal failure is a malignant disease. Dilatation may continue for some time without enabling a positive diagnosis for or against malignant disease to be made. These cases also suggest the thought, Are they malignant from the beginning, or does the cancer develop as a result of the dilatation and inseparable chemical disturbance? Age is not a reliable factor in determining the diagnosis. The writer recently had under observation a patient, aged thirty-two years, on whom gastrostomy had been performed for malignant occlusion of the esophagus, and who presented strong evidences of cancer,[1] besides indubitable ones of dilatation of the stomach. Here the dilatation seems to have been the original disease and to have been due to habitual use of enormous quantities of beer, four gallons being said to have been a customary daily allowance.

On the other hand a pyloric tumor is not necessarily malignant. Rosenheim cites such a case in which the diagnosis was confirmed by a number of careful observers who noted the gradual growth of the tumor, afterward explained as due to progressive emaciation, and the usual cachexia and symptoms of cancer. On autopsy the growth was found to be entirely fibroid. Had it not been for the confirmed diagnosis of cancer, gastro-enterostomy would have been performed and recovery would probably have occurred. Einhorn has reported a number of similar cases but considers pylorectomy or pyloroplasty as the ideal treatment.

Deplorable as the fact is we must acknowledge that positive diagnosis of gastric cancer cannot be made in time for radical surgical operation in the present state of our knowledge. The diagnosis may sometimes be made with considerable probability, but usually the patient should be sufficiently informed as to the probabilities and possibilities to take upon himself the responsibility of accepting or refusing a sufficiently early exploratory operation. The fact already referred to, that the major part of digestion is performed by the intestine, renders the prognosis of non-malignant gastric diseases of all kinds quite directly dependent upon the state of the motor function.

[1] Cancer of the stomach involving the left lobe of the liver, besides an esophageal tumor, verified by autopsy.

CLINICAL MEMORANDA.

AN INTERESTING CASE OF HYDROPHOBIA: RECOVERY.

By JOHN J. LIGGET, M.D.,
of Ladiesburg, Md.

February 14, 1878, D. S., an American laborer, aged thirty-four years, weight 140 pounds, married, informed me by a messenger that he had pains in his stomach and side, and desired some purgative medicine. I sent him some compound cathartic pills with directions to take two at night and one in the morning. February 15th, at 10 A.M. I visited him and found that he had had two evacuations after taking the pills. He fainted soon after 8 A.M. He was lying in bed, had pains in the epigastrium and was indisposed to talk. His pulse was normal, but he had convulsive tremors in all his limbs. I suspected malingering, and left a placebo, directing that sinapisms be applied to the epigastrium and along the spine if the tremors continued. At 5 P.M. I received an urgent call to visit the patient who had had spasms since 4 P.M. I was unable to visit him that evening, but sent him chloral hydrate, 75 grains in solution, which was taken in 15-grain doses from 10 P.M. until 4 A.M. on Saturday. He had thirteen convulsions during this time.

February 16th at 8 A.M. I found him in a strong convulsion. Five able-bodied men were laboring to keep him in bed. Was very violent and endeavored to seize those around him with his teeth and hands. Profuse secretion of viscid saliva. Head cool, pupils sensitive to light during spasm, pulse slightly frequent and tense. Bled him to the amount of ℥ xxiv. Symptoms of syncope. In half an hour free alvine and urinary discharges occurred. Spasms ceased for an hour, and then returned as strong as before. He drank a little water just before the spasm; there were convulsive movements of the glottis before, during, and after drinking. Consciousness perfect between the spasms. Could always give warning of an approaching attack. Suspecting an inflammatory condition of some of the nervous centers, I gave him at 10 A.M. half a grain each of morphin sulphate and antimony and potassium tartrate. This had but slight effect, and in two hours I repeated the powder. Applied sinapisms to ankles. At 9 P.M. the spasms had been less violent since noon. The patient had taken four powders since 10 A.M., as well as 3 ounces of rum. Tenderness over tenth dorsal vertebra; applied a small blister at 10.30 P.M. Had previously tried to inject morphin subcutaneously in back, but failed as the pricking of the needle produced a convulsion. A teaspoonful of water

in the mouth produced a spasm. Before a convulsion he would lie perfectly motionless, answering questions, eyes closed, and breathing laboriously. Then a lateral motion of the eyes beneath the lids would commence, and in a minute or two the eyelids would open to their widest extent, and the gaze be fixed on the ceiling. Suddenly he would spring as though acted upon by a powerful electric apparatus, get up on his hands and knees and be nearly out of bed before he could be seized. He would then be turned on his back, and held only by great effort. He would make desperate efforts to bite those about him, would forcibly eject saliva from his mouth. Apparently a series of galvanic shocks would start from the head and radiate along the spine and extremities. The breathing during a paroxysm was hurried and difficult. The jaws were perfectly mobile. An onion was held near his mouth and he instantly snapped at it with his teeth during one of the paroxysms. During a paroxysm the fingers and thumbs could be flexed or extended at will. A light brought to the bed would instantly produce an attack. I gave the fifth powder of morphin and antimony tartrate at 10 P.M. and at midnight gave him 1 grain of morphin and ½ a grain of antimony and potassium tartrate. At this time I was told that the patient had been bitten a year or two before by a dog believed to be mad. The precise date was not recollected. Examined a well-marked cicatrix on leg, but could detect nothing abnormal. Patient said that the bitten leg had pained him several days before his illness. Perceiving no effect from the last powder I repeated it at 2 A.M., and left him an hour later. Prognosis very unfavorable.

February 17th, 9 A.M. Found patient in same condition. He had taken two more powders. Blister had been removed at 4 A.M. Had drawn well. At 11 A.M. consulted with Dr. Milton A. Lauver of Bruceville, Md. At 12 M. while the patient had a spasm, Dr. Lauver applied a small quantity of water to his neck and breast. He became furious. The laryngeal and respiratory muscles were powerfully affected. At 1 P.M. gave him 2 grains of morphin sulphate. At 4 P.M. he was given morphin sulphate 2 grains and antimony and potassium tartrate ½ a grain. He had six terrific convulsions from 1 to 5 P.M. In our consultation Dr. Lauver and I coincided in the diagnosis of hydrophobia. From present indications the patient must inevitably succumb to the disease, and the line of treatment, if persevered in, would be extremely hazardous. In thirty hours he had taken 10½ grains of morphin and 5 grains of antimony and potassium tartrate. Dr. Lauver and I returned to my office and examined the *American Journal of the Medical Sciences* for January, 1860. My father, Dr. John E. H. Ligget of Middleburg, Md., had reported a case, which he believed to be hydrophobia, in that journal. The patient was a female and had recovered. We believed that the only way to save the patient's life would be to follow my father's treatment.

February 17th, 6 P.M. Gave patient calomel 3 i, in a spoon mixed with a little syrup. He took it with some effort. In half an hour he became quiet and fell asleep. Pulse 72, respirations 12. Aroused the patient at 8.30 P.M., when he asked for water. Gave him a gill, and in eight minutes he had a moderately severe spasm which lasted twenty-five minutes. After spasm micturition occurred for the first time in thirty-six hours. At 9 P.M. gave him calomel grs. x. Rested quietly and became talkative. At 10 P.M. symptoms of catharsis. Gave tincture of opium 3 ss, and left him for the night. February 18th, 10 A.M. Found patient better. Had taken calomel as follows: 20 grains at 12.30 A.M.; 3 i at 4 A.M.; 20 grains at 6.30 A.M. Had four convulsions from 10.30 P.M. until 10 A.M. Pulse 80, respirations normal. Paroxysms had been mild and lasted from fifteen to thirty minutes. As soon as the attacks ceased he was given calomel 3 i. For four hours he rested perfectly. At 10.20 P.M. he felt another attack coming on. Gave him calomel 3 ss, which arrested it at once.

February 19th, 10 A.M. Found patient just over a paroxysm caused by noise of children. Lasted twenty minutes and was moderate. First spasm in twelve hours. Bowels had moved moderately twice. Dejections dark green. About same time vomited some green viscid mucus which contained some of the unabsorbed calomel. Salivary secretion free. Mouth not sore. Tongue clean. Asked for coffee, milk, etc., which he drank in small quantities. February 20th, 9.30 A.M. Patient resting quietly. No return of paroxysms. Bowels moved slightly at 5 A.M. Some vomiting and considerable retching during night. Ulcers making their appearance on the inner surface of the cheeks. Salivary discharge free. Castor oil, ℥ i, given at 2 P.M. February 20th, 8 P.M. The oil acted twice, moderately. Dejections green. Symptoms of ptyalism pronounced. Takes milk every two hours, and occasionally a cup of coffee with bread in it. Kidneys acting well. Complains of soreness and stiffness about the nucha. Directed gargle of infusion of white-oak bark with alum and honey. (Quer. alba cort., a small handful, aqua bulliens Oi, alum ℥ i.) February 22d, 5 P.M. Quiet since last report. Mouth and ala nasi sore. Pain and stiffness in jaws. Gums swollen and spongy. General stiffness of the muscles. Takes nourishment freely. Sleeps some when everything is quiet. In conversation he told me that during the previous week he was irritable. Quarrelled with his wife. Said he had to make a strong effort to drink water or other fluids. The sound of pouring water made him tremble. During the spasms he felt a disposition to tear or rend everything around him. He believed that a cupful of water poured on him would have given him the strength of a dozen men. Said that he felt something like a knife cutting his stomach during the spasms. He then described a feeling of numbness in both ankles before each attack, which ascended in waves toward his head, and when it reach his breast he was seized with the paroxysm. Said he felt a dread of something he could not describe.

March 3d. The patient sat up all day. Appetite very good. Bowels regular. Has been taking subcarbonate of iron since Wednesday last. Mouth nearly healed. Says that he feels some aversion to water. Pouring water causes a thrill through his whole body. Occasionally has frightful dreams in which a large yellow dog

plays a prominent part. March 6th. He walked out to-day and I ceased attendance. In a month he was in robust health, and engaged in his usual occupation. Amount of calomel exhibited in Dr. J. E. H. Ligget's case 270 grains; in my case 260 grains.

A CASE OF HYDROPHOBIA.

By C. GERSTMEYER, M.D.,
of Terra Haute, Indiana.

I was called to see the little daughter of J. K., living one mile south of Terra Haute one night at two o'clock. The father was walking the floor, with the child's arms clasped tightly about his neck. The child's countenance was expressive of great terror. The father said the child would have a convulsion if he ceased walking. I walked by his side and touched the child's hand, when she had a terrible convulsion. When the spasm had subsided she begged me not to come near her or touch her again. I sat down, the father continued walking the floor and the child continued to have convulsive "shivers." The mother asked me what ailed the child. I said I did not know, I had never seen anything like it before.

The mother then said that they had had a vicious but useful watch-dog which they kept tied up in the day-time and turned loose at night. He would run over to the slaughter-house and fight with other dogs. One morning about six weeks ago her husband called the dog but the dog was sullen and would not come so he dragged him to the kennel by his collar and tied him. At 10 A.M. the little girl went to the kennel to feed the dog when he bit her in the face. When Mr. K. came home he killed the dog. The wounds in the child's face healed quickly and there was nothing unusual noted until the previous evening. The children had peanuts and the little girl said laughingly that she could not chew them. Later at supper she rather peevishly complained of not being able to swallow her tea and ate no supper. After supper she played with the children as usual. At midnight the parents were awakened by the child's screams. She was in convulsions and looked as if she was badly frightened and wanted to hold on to her father. She was perfectly rational.

I remembered that some one advised the application of cold water to the spine and back to control the convulsions of hydrophobia and asked the mother to get some towels and cold water. The father was still walking the floor and I applied the wet towels to the child's back. She promptly had the most fearful convulsion I ever witnessed but I persevered with the cold applications until the child asked to be put to bed. The cold applications were continued, she had no more convulsions and went to sleep.

I saw her again the next morning. She was in bed and her mother said the spasms could be controlled by the cold applications. I saw her again at 2 P.M. She was sitting on her father's lap, had a frightened expression of countenance, looked rather wild, and was very talkative. She said to me, "Doctor I am better, give me some medicine, I want to get well." I put a few drops of spirits of niter into a cup of water and offered a teaspoonful to her. She said, "No, let me have the spoon." I held the cup so she could dip out the supposed medicine herself. The movement of her hand from cup to lip became more and more rapid until she became convulsed all over. She could not swallow. My next visit was at 10 P.M. She was dead. The mother told me she had no more convulsions after I left. At 6 P.M. she ate some bread and butter with tea which she seemed to relish. She then fell asleep and died without wakening and without a struggle.

THERAPEUTIC NOTES.

Partial Resection of the Testicle for Tuberculosis.—Delore (*Centralbl. f. d. Krank. d. Harn- und Sexual-Organe.*, January 21, 1899) advocates an exploratory incision along the convex border of the testicle in cases of tuberculosis of this organ, to be followed by a partial resection of the diseased tissues leaving as much of the rest as may be. The inspection of the testis from its surface often gives a false impression that it is sound when there are nodules of tuberculosis in its center. This danger will be avoided by splitting it up in the manner advised, when after removal of any such nodules the organ may be sutured. The presence of even a portion of the testis in the scrotum, after the removal of the epididymis, is of considerable value to the individual from a sexual point of view.

Treatment of Soft Chancre.—Grineperte (*Rev. de Therapeut.*, January 13, 1899) has employed in ten cases of soft chancre the following treatment: Twice a day a local bath is given in a 2-per cent. solution of creolin at a temperature of 38° to 42° C. (100° to 108° F.), lasting for fifteen to twenty-five minutes. The ulceration is wiped and powdered abundantly with salol and bandaged. In two or three days it dries up entirely and does not secrete any more. At the end of a week cicatrization commences and completes itself in two or three days, forming a solid elastic scar. The baths are to be continued until the healing is complete. The average duration of treatment was eleven days.

Two New Methods of Treating Sciatica.—Bucelli (*Gaz. heb. de méd. et de chir.*, February 12, 1899) applied the method of Negro (cutaneous digital compression) in fifty-four cases of sciatica, with good results. In all the patients who were cured, the sciatica was of recent date, nine to forty-seven-days' duration, and no marked neuritis was present. Amelioration usually appeared at the end of the first treatment, and increased progressively. In general it may be said that the treatment by compression had a better effect in the cases in which the pain was located at definite points, and in which there were no trophic disturbances. Another method of treatment, that advised by Bonuzzi, was applied in thirty-two cases with the result of a complete cure seventeen times and improvement ten times. The patient was stretched upon his back on a horizontal plane. The trunk was held firmly by an assistant, and the chief took hold of the fully

extended leg, and flexed it as far as possible on the body, the knee being held straight meanwhile. This was done slowly and thoroughly. This method of treatment, was most successful in cases of neuralgia pure and simple, without complication of neuritis.

Solution of Calcium Chlorid in Gynecology.—Calcium chlorid, says a writer in *La Presse Medicale*, December 24, 1898, is an antiseptic of great power and deserves an especial place in gynecologic treatment because of its faculty of dissolving albumens, while corrosive sublimate, creasote, nitrate of silver, etc., coagulate albumen and are thus prevented by their own action from contact with the diseased surfaces. A strong solution is made in the following manner: Three ounces of fresh calcium chlorid is added to thirty-six ounces of water. The mixture is shaken and allowed to stand one hour. It is then filtered through double paper into a bottle holding one quart. This bottle should be of dark glass and closed by a glass stopper, sealed with a little paraffin. For use a glass of this strong solution is mixed with nine glasses of hot boiled water, so that the whole shall have a temperature of 40° to 50° C. (105° to 122° F.). This solution may be employed in lotions, douches, compresses, and tampons; in vulvovaginitis, endocervicitis, both external and internal, in inoperable cancer, etc. It shortens the duration of acute inflammation considerably, and is particularly useful in the treatment of endocervicitis, with glairy mucous discharge. Such a solution of calcium chlorid, the cost of which is almost nothing, is ten times more valuable as an antiseptic than bichlorid of mercury and, being neither caustic nor poisonous, may be safely used for intra-uterine injections in puerperal infection.

Wet Dressings of Alcohol.—ZANGGER (*Lancet*, January 28, 1899) has produced the greatest relief in inflammations of various kinds, felons, lymphangitis, furunculosis, etc., by covering the inflamed areas with gauze and cotton saturated with strong alcohol. Over this is placed a sheet of gutta-percha tissue to prevent the alcohol from evaporating, and the whole is held in place by a bandage. In numerous cases such a dressing was used alternately with a wet-dressing of 1 : 2000 bichlorid of mercury in water, or after the failure of such a dressing to control the pain and swelling, and the rapid improvement under the alcohol applications left no doubt in his mind that it was far superior to a watery dressing. The dressings are not serviceable in chronic glandular swellings.

The Treatment of Delirium Tremens by Atropin.—TOUVIME (*La Semaine Med.*, January 11, 1899) has tested in some forty cases the effects of the injection of atropin in the delirium of alcoholism, and has found that the injection of 1/200 to 1/150 of a grain if preceded by a warm bath and cold applications to the head will generally suffice to quiet a patient in twenty or thirty minutes. In certain cases the good effects are delayed however for some hours. If there is much muscular action the drug has an exciting effect for a few minutes, and then its calming action begins. Such a patient should receive as his first injection only half the maximum dose, and every ten hours a slightly increased dose, until the maximum of 1/150 of a grain is reached. Usually only two or three injections will be necessary. If there is pneumonia the baths are omitted. In very severe cases of delirium Touvime begins treatment with the administration of 80 or 90 grains of diuretin in an ounce of water. This produces sleep, and after that the atropin is injected.

A single injection of atropin each day is of benefit in the exacerbations of dipsomania. The patient should be kept in a somnolent condition by the administration of the following mixture, which is to be given in teaspoonful doses every fifteen to thirty minutes till the desired effect is obtained:

℞	Chloral hydrat.	ʒ ijss	
	Ext. thebaic	gr. j	
	Aquæ	℥ vj.	M.

Milk-Leg in Typhoid Fever among Soldiers.—DA COSTA (*Internat. Med. Mag.*, January, 1899) found that twelve per cent. of 135 soldiers treated for typhoid fever in the Pennsylvania Hospital suffered from milk-leg. This is six or eight times as frequent an occurrence of this complication as has generally been noticed. No sufficient reason could be assigned for this, as they had not been subjected to long marches or other exhausting exercise. This trouble has usually been ascribed to phlebitis, but there is not necessarily any inflammation of the vein antecedent to the thrombosis. If present it causes pain, which is otherwise absent. The leg should be elevated, and hot lead-water or witch-hazel applied to relieve pain, to be followed by strips of belladonna plaster if pain continues. Absolute rest is essential. It is of the utmost importance that the patient does not get out of bed too soon. When he does get up he should have either an elastic stocking or flannel bandage. Sometimes there will be pain and swelling of the leg for as much as eighteen months afterward.

Treatment of Tubercular Cystitis by Iodoform Oil.—RENIAC (*Gaz. heb. de méd. et de chir.*, January 29, 1899) reports fourteen cases of tuberculosis of the bladder which were treated by iodoform in liquid vaseline. Since the oil floats upon the surface of the water in the bladder, it is possible for the patient by stopping the stream as soon as the first drop of oil appears to retain the oil in his bladder for several days or a week or two. When it has all been ejected a new quantity is introduced, usually an ounce, containing 25 grains of iodoform. By this means there is made a continual application of the medicated oil to the diseased parts, and not only are the pains relieved, but the healing effect of the iodoform is manifested to a marked degree. Of the 14 patients so treated, 6 were greatly improved, 7 were improved, and only 1 was not favorably affected.

For Cardiac Disturbances During Thyroid Treatment.—It has been found by BEDARD and MABILLE in experiments on dogs, that if Fowler's solution be administered during a course of thyroid treatment no cardiac disturbances occur. The application of this fact in human practice has, therefore, been suggested.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS in the form of Scientific Articles, Clinical Memoranda, Correspondence, or News Items of interest to the profession are invited from all parts of the world. Reprints to the number of 250 of original articles contributed exclusively to the Medical News will be furnished without charge if the request therefor accompanies the manuscript. When necessary to elucidate the text illustrations will be engraved from drawings or photographs furnished by the author. Manuscript should be typewritten.

SATURDAY, MARCH 18, 1899.

RABIES IN AMERICA.

The New York Board of Health has performed a distinctly meritorious as well as scientific service to the American medical profession in seriously taking up the investigation of the existence in this country of rabies or hydrophobia. The results of that investigation up to date are presented in Dr. Follen Cabot's paper which appears in this issue. Those interested in the subject (and what medical man is not?) will find some further interesting facts in the discussion of Dr. Cabot's paper at the meeting of the Section on General Medicine of the New York Academy of Medicine which is also published in this number.

For various reasons a certain amount of doubt has existed in many, even medical, minds as to the occurrence in this country of genuine hydrophobia. From this false assumption has come at times the thought, not infrequently expressed, that hydrophobia in Europe might be only a delusion, a severe functional neurosis on a psychic basis, rather than the dread disease itself. Pasteur's reputation as a great scientist has suffered in the minds of many American physicians because of his invention of the preventive treatment of rabies. Certain American views on this matter have been the subject of no little opprobrium abroad. The calm assumption by certain people that practically the whole profession of several great European nations could be utterly deceived on a subject like this was almost too much to forgive to even American self-sufficiency. The quizzical looks that gathered on Russian doctors' faces at the last International Congress at Moscow, when an American medical visitor said that there were doctors in America who doubted the existence of hydrophobia, was one of the silent but indelible impressions of the meeting. The Russians could only think of it as a huge joke after the American fashion, for rabies needs no special seeking to be found in Russia.

Cabot's work, in connection with the laboratory of the New York City Board of Health, shows that rabies unfortunately does exist in this country. A number of indubitable cases have occurred recently on Staten Island. There were, not long ago, at least two foci of the disease in New Jersey, as the discussion at the New York Academy of Medicine shows, while Dr. Frothingham is authority for the statement that a series of cases of true rabies is in progress, at least among animals, in the vicinity of Boston. We have reported in our columns two cases from Long Island within the past two months in which inquiry among medical men who had been close to the patients gave us practically the assurance that they were cases of true rabies. We printed the report of a case from one of the Western States not long ago, and we publish two more this week in which the evidence seems conclusive that the disease at work was genuine rabies.

Now our object is not to raise a disquieting mad-dog scarce, nor to terrify people accidentally bitten by a perfectly healthy pet animal into rushing off to receive the Pasteur preventive treatment for rabies. Even when bitten by a really rabid animal the chances of hydrophobia developing in any particular case are not very great. Bites are often through the clothing and the infectious material is absorbed from the fangs by the cloth and does not reach the circulation, and in cases in which the bites are on exposed parts the person bitten is in many instances not susceptible to the disease at the moment and escapes infection. We wish merely to insist on the

fact that rabies exists among us here in the United States and that proper precautions to prevent its spread are necessary.

There are entirely too many vagrant animals on our streets. They are liable to be the sources of other diseases besides rabies. Dr. Cabot's and Dr. Frothingham's remarks as to quarantine and the registration of dogs deserve the most serious attention. An educated public opinion in the matter will do much to make possible the enforcement of existing laws and smooth the way for future enactments. Too many medical men in this country have held halting views on the subject of rabies, and the result has been a failure to disseminate among the public well-grounded intelligent information regarding the regulation of the life and habits of dogs. Proper precautions rigidly enforced for a few months with observation of suspected animals would rid us entirely of all danger in the matter. Let us hope that the work so well done by our Board of Health will not be unproductive of beneficial results.

ANIMAL SUFFERING VERSUS HUMAN SUFFERING.

WE have purposely refrained from commenting on a subject that occupied quite a little public attention some weeks ago, because we wished the medical side of the case with regard to hydrophobia to be before the public in order to lend weight to our comment. There is no longer any possible doubt of the existence of the disease in our neighborhood nor of the fact that within the last year or two at least three human beings have died of it.

Knowing these facts it is clear how completely unjustifiable was a recent decision of certain authorities of the Society for the Prevention of Cruelty to Animals of New York City, in refusing to give up certain parts of a suspected animal that had bitten certain people residing near a recognized focus of the disease, in order that it might be decided definitely that the animal had or had not had rabies. The Society for the Prevention of Cruelty to Animals pooh-poohed the idea that rabies existed on Staten Island, and had an autopsy of the animal made from which they pretended to be able to conclude that it had not died of hydrophobia. What possible grounds the Society could have for such assurance in the present state of our knowledge of the post-mortem lesions of rabies no one can imagine, but it absolutely refused to allow any portions of the dead animal's medulla to be used for inoculation into other animals though all authorities are agreed that that is the *only* way to decide *with certainty* as to the existence or non-existence of rabies in a given case.

The inoculations, if successful, would have given to two animals for a few days a modicum of pain; for animals, as a rule, acquire the dumb or paralytic form of the disease. If the inoculations had failed to produce the disease human beings would have had lifted from them a serious weight of mental suffering extending over months. All necessity of submitting to the inconveniences of the Pasteur treatment would have been dismissed from their minds, and their friends would have been at once relieved of all anxiety. On the other hand if the inoculations had proved successful, definite absolute indications for treatment of the individuals affected would have been present, as well as for definite steps looking to the welfare of the community.

All of this was prevented by the unwarrantable presumption of the Society for the Prevention of Cruelty to Animals: (1) that rabies does not exist in the neighborhood of New York; (2) that the suffering of one or two animals for a few days is to be weighed against prolonged serious human suffering and an important question of public health; and (3) that the final adjudication of the question must rest upon an exaggerated disproportionate sympathy for animal suffering.

We are thoroughly in sympathy with the movement for the prevention of unnecessary suffering on the part of animals. We appreciate the great good work that the Society for the Prevention of Cruelty to Animals has done in this country, but we deprecate these exhibitions of a false sentimentality in favor of animals that sometimes characterize the action of certain members in authority in the Society. Let us care for the animal by all means, but let us bear in mind that our brother-man must be the first object of our care. Let us look at things in their proper proportions and appreciate the relations among creatures, without allowing hyperesthetic sensibility, fostered by the autosuggestion of endowing animals with feelings that only supersensitive human beings have, to fatally warp our judgment and hurt the very cause we are trying to help.

PNEUMONIA AND THE DOCTORS.

Under the above caption the *New York Times* of Monday last comments editorially on Mr. Kipling's recovery from his recent severe attack of double pneumonia. "Hereafter," says the *Times*, "when a physician loses a pneumonia patient of good constitution and under forty what excuses can he hope to give that will satisfy the friends of the deceased? We do not see that he can give any. They will be prone to believe that what has been done can be done again."

This comment is typical of the position the non-medical mind is very apt to take with regard to medical questions, because it assumes a simplicity of process in disease that scientific medical progress is showing us clearer every year exists nowhere in the domain of pathology.

Even in uncomplicated cases physicians are not called upon to treat simply the pneumonia but the patient suffering from pneumonia. At a given moment the tissues of a certain individual, for reasons in many cases not quite clear, become a favorable culture medium for the growth of a little plant, the pneumococcus. This little plant is present very often in the sputum of healthy individuals for long periods without causing any untoward effects. Once it has taken root, as it were, its growth depends on the continuance of the favorable tissue conditions that allowed the original implantation. Natural forces in the body at once begin to react to preserve the human organism. It takes a certain number of days, usually 5, 7, or 9, before the so-called critical period is reached and Nature's triumph is announced.

Medical science at present can do nothing to abort the pneumonic process. Physicians can only stand by and assist natural forces in their struggle, can only watch for the first sign of flagging heart to stimulate it judiciously, can only combat the weakening effect of excessive temperature by the various antipyretic methods. The ultimate issue of the struggle depends on the patient's constitution and his power to react against the physical conditions mechanically interfering with respiration in his lungs, and the toxins which are produced during the growth of the pneumococcus and absorbed into the system. Some idea of the poisonous nature of these toxins may be gathered from the fact that they are probably not unlike the alkaloidal poisons, strychnin, aconitia, morphin, and the like, which, it is to be remembered, are also of vegetable origin. For despite the oft-repeated cry of the quack that his medicines can do no harm because forsooth they are herbal remedies, *i.e.*, are obtained from plants, it is from the vegetable kingdom that medicine derives her most potent drugs.

Had we an antitoxin for pneumonia as we have for diphtheria then we would be able to attack the disease directly, for if we could prevent the weakening of the system by neutralizing to the toxins Nature would very soon dispose of the pneumonic process in the lung as she does of diphtheria under similar circumstances; we could anticipate the crisis before any serious organic exhaustion had taken place. We cannot, however, and so our treatment for the present at least is only supporting. As a rule, with very few exceptions, "pneumonia patients of good constitution under forty" react successfully against the disease, but in no case can an absolutely favorable prognosis be given and for reasons which may be briefly summarized as follows: First, seemingly healthy people often reveal unexpected weak points in their systems under the strain of disease. Second, the pneumococcus does not limit itself to the lungs in some cases but invades other organs, even the central nervous system, making serious complications. Third, different varieties of the pneumococcus are very variously virulent, *i.e.*, some of them produce much more toxins than others, just as one poppy-plant produces more opium and its alkaloid morphin than another. Fourth, sometimes at the same time with the pneumococcus other micro-organisms are implanted in the lungs. This is notably the case with the influenza bacillus in times when that disease is epidemic. As may be readily understood the absorption of influenzal toxins with those of pneumonia adds seriously to the danger. Fifth, at times so-called pneumonia is not due to the pneumococcus but to other micro-organisms that often in mixed infections produce the signs of consolidation to be found in ordinary pneumonia. These cases run a very irregular course and the crisis is often delayed or absent.

Because the exercise of the highest medical skill and the most careful nursing has fortunately saved Mr. Kipling there is no reason why even the same

skill and care will save every other patient. The *Times* says very well: "Eternal vigilance is the price of success in the treatment of pneumonia patients. It was the unremitting and skilled attention, the uninterrupted readiness at every instant to give the patient the help he needed in the fight that saved this indispensable life to his family and the world of letters." It is the supremest care that guarantees as far as lies in human power against a fatal issue in pneumonia; but even with this care there will, until the much-wished for, much-worked for, specific medication of an antitoxic serum comes, always be some fatal terminations of the disease even under circumstances that at the beginning seem favorable.

NOTABLE BOOKS.

We present this week a review of Professor Landouzy's "Clinical Lessons in Serum-therapy." It forms the first of a series of reviews which will appear in our columns during the present year, of the most notable, recently published books. Only books of general interest by great teachers and investigators, or which are conspicuous by their unusual merit, books that every one should know at least something about, will find a place in this department.

Professor Landouzy's instructive *résumé* of the present state of serum-therapy will be followed by a review of the latest work of Professor Waldeyer, the distinguished anatomist of Berlin, entitled "Das Becken" (The Pelvis). This in turn will be succeeded by "Guia Practica, Higienica y Medica del Européo en los Países Torridos (Filipinas, Cuba, Puerto Rico, Fernando Poo, etc.)," by Federico Montaldo. (A Practical, Hygienic, and Medical Guide for the European in Torrid Countries (especially the Philippines, Cuba, Puerto Rico, etc.). The work was crowned by the Royal Academy of Madrid just before the Spanish-American War, as a book designed to furnish accurate information to intending colonists in the Spanish possessions that have since become ours. A review of the work on "Hirn Chirurgie," by Professor von Bergman of Berlin in its latest edition will follow in due course, and other books of the same practical, scientific, and progressive character will have a place.

ECHOES AND NEWS.

Health of Havana Improving.—The death-rate at Havana for the week ending March 3d was lower than at any time since 1894. During the week there were 187 deaths from all causes. There were no deaths from either yellow fever or smallpox.

The Climate of Cuba.—Dr. John Guiteras, in a lecture delivered at the University of Pennsylvania on March 6th, stated his opinion that sixty per cent. of Americans who go to Cuba for the first time will contract yellow fever, and the death-rate among the sick will be from five to six per cent.

Total Deaths in the Army.—On March 10th the following statement was issued at Washington showing the total number of deaths reported to the Adjutant-General's Office between May 1, 1898, to February 28, 1899: Killed in action, 329; died of wounds, 125; died of disease, 5277; total, 5731.

Poison in Wall-Papers.—Dr. E. M. Chamot of the Chemical Department of Cornell University states, as a result of a chemical analysis of wall-paper, which he has been carrying on for several months, that nearly all wall-paper sold at the present time contains arsenical poisons, some of them in large quantities.

Trained Nurses Celebrate. — More than 800 trained nurses, representing twenty different schools, celebrated at the Waldorf-Astoria Hotel on the evening of March 6th the formation of the first class of trained nurses in Bellevue Hospital twenty-five years ago. Many physicians were present. The orator of the evening was Dr. William M. Polk.

Dr. Deaver to Leave the University of Pennsylvania.—The resignation of Dr. John B. Deaver, as Assistant-Professor of Applied Anatomy, has been tendered and accepted to take effect at the end of the present academic year. By this resignation the Medical Department of the University loses another eminent instructor and valuable member of its teaching body.

An Anniversary in Honor of Volta.—On May 4, 1899, the city of Coma, in Italy, will celebrate the hundredth anniversary of the day on which Volta, one of her citizens, invented the pile which goes by his name. On this occasion an International Exhibition of Electricity will be held, and a section will be devoted to the various medical applications of electricity.

Home for Aged Invalid Poor. — The Pringle Memorial Home of New York City was incorporated on March 3d. Its purpose is the care of invalid, aged, and indigent men. Dr. Albert W. Ferris of New York, Richard B. Ferris of Mount Vernon, Stephen V. White of Brooklyn, James W. Manier of Binghampton, and Clarence M. Trent of Buffalo are the directors.

Factors in the Production of Degeneracy.—E. S. Talbot, M.D., D.D.S., of Chicago, in his book on "Degeneracy,

Its Causes, Signs, and Results," considers tobacco a causative agent of greater importance than alcohol or opium. He regards intolerance of alcohol an expression of degeneracy. Opium is in his opinion a considerable factor in the production of insanity.

Board of Examiners in Lunacy.—There has been introduced in the Legislature at Albany a bill providing for the appointment of a Board of Lunacy Examiners for New York City, to consist of eleven physicians (one of whom is to be the chief examiner), in place of the four physicians who have heretofore done the work for the greater part of the territory now embraced within the enlarged city.

Chlorin in Pneumonia and Diphtheria.—Dr. Bracelin's "corrected chlorin," which has already been used at the Kingston Avenue Hospital, Brooklyn, is now employed in the treatment of diphtheria at the Willard Parker Hospital for Contagious Diseases in New York City, where it is used to some extent in the place of antitoxin. The New York City Health Department is also experimenting with this gas in cases of pneumonia.

Hospital Ship at Savannah, Ga.—The United States Hospital ship "Missouri," arrived at Savannah, Ga., on March 10th from Cuba with 226 sick soldiers. The sick troops will be placed in the Government Hospital at Savannah which has just been completed. The men are suffering from malaria, rheumatism, typhoid fever, and from the results of traumata. None among the soldiers is dangerously sick. Quite a number are from the 202d New York Regiment.

"Curtain-Faced Man" is Dead.—Michael Kelly, sixty-four years old, Bellevue's oldest patient, died in Ward 3 on March 7th after a continuous residence of twenty-five years in the hospital. His disease was fibroma molluscum. There were a great number of fibromata upon various portions of his body, the most conspicuous of which was an enormous pendulous mass extending from his scalp down over his neck. He was a subject of demonstration at many medical lectures.

Mr. Kipling's Physicians Congratulated. — At the regular bimonthly meeting of the Council of New York University on March 6th the following resolution was adopted: "The New York University Council hereby extends its congratulations to the Dean of the Faculty of Medicine, Dr. E. G. Janeway, and his associate in the Faculty, Dr. Theodore Dunham, upon the success which has attended their efforts to save to the cause of letters and of mankind the life of Rudyard Kipling."

New School for Nurses in New York.—The training-school for nurses at present connected with the New York Post-Graduate Hospital is to be supplanted by a new school, which will cost $100,000, and which will be known as the Margaret Fahnestock Training-School for Nurses of the New York Post-Graduate Hospital; it is founded by Harris C. Fahnestock in memory of his wife. Three lots in Twentieth street, opposite the Post-Graduate Hospital, have been purchased, and it is expected that the building, which will contain accommodations for seventy or more nurses, will be completed within the year.

New Cornell Medical College.—The plans for the new medical college which Colonel Oliver H. Paine will present to Cornell University have been filed. The building will be five stories high and will cover the entire west side of First avenue from Twenty-seventh to Twenty-eighth street. There will be three great amphitheaters, two of which will be two full stories in height. The dissecting-room will be 50 feet wide and 170 feet long and will be lighted by the largest skylight in New York City. Steam-heat, electric lights and a refrigerating plant will be features. It is expected that the building will be ready for occupancy by the fall term of 1900.

The Death-Rate at Chickamauga.—A statement compiled in the Adjutant-General's Office at Washington shows that the deaths from disease from the first occupation of the camp at Chicamauga in the middle of April to its abandonment in the middle of September, and including the four battalions which remained to January 1st, were 341, or a little less than half of 1 per cent. The deaths of the Volunteer force which was mobilized at Camp Thomas up to December 2d, which was 2½ months after they had been withdrawn from Camp Thomas, and after the close of all campaigns in which any of them participated were for this period of six months 1.61 per cent.

Perfection in Illustrative Art.—The most striking reproduction in colors of a pathological specimen that we have ever seen, the most perfect in its finish, in its truth to Nature, in its delicate coloring, and complete detail is contained in the current number of *The Journal of Experimental Medicine.* It is the picture of the heart taken from a case of gonorrheal endocarditis, which is reported by Drs. Thayer and Lazear of Johns Hopkins. Dr. Thayer presented the original water-color drawing of the specimen before the Section of Medicine at the International Congress at Moscow where it made quite a sensation among the foreigners, was greatly admired, and elicited frequent enquiries as to how it was done and where, and who, had done it. We are glad to see that this artistic gem has been reproduced so worthily. It is a distinct step in advance in medical illustration at least. The editorial management and publishers of *Experimental Medicine* have our congratulations on the new model for imitation which they have furnished medical illustrators all over the world.

Human Rabies in the Philippines.—It seems of interest to note, as we happen to be devoting considerable space to hydrophobia this week, that there are two distinctly characteristic forms of this disease that occur in the Philippines as a consequence of the bites of rabid animals. According to the *Cronica de Ciencias de Filipinas* (we believe this is the first time that a medical fact has been gleaned from a scientific journal published in our new possessions) the disease under one of these two forms is by no means uncommon on the islands. The writer of

the paper describes a form in which the sight of water or of anything that suggests swallowing, sets up spasms that become general. In a severer form which he calls arophobia, the slightest sensory disturbance, a breath of air, a flashing reflection from a shining object, a slight noise, will initiate the spasmodic attacks. Besides these divisions of the disease according to its severity there is another classification made; the furious and paralytic forms of the disease. It is noted that the furious form may be accompanied by a maniacal excitement while the psychical manifestations of the paralytic form are usually the symptoms of depression and melancholia. The therapy of the disease consists of prompt cauterization followed for weeks by some form of herbal tea that causes profuse respiration. Under this method of treatment most of the cases are said to recover. Unfortunately no statistics or details of cases are given to substantiate this very interesting statement. We cannot refrain from remarking that the whole exposition of the subject however, is thoroughly scientific. The forms of the disease described are well known especially in animals. The fact that the spasms in severe cases are initiated by a breath of air, has been looked upon as almost pathognomonic by the last European authority who treated the subject of hydrophobia exhaustively, in the article on "Lyssa" in Professor Nothnagel's series on "Special Pathology and Theraphy." We shall evidently find some brothers in the profession in the Philippines who are not unworthy of their new relation with the American fraternity. If they have, as this one seems to have had, a little over confidence in the effectiveness of their remedies we do not think that they will for that reason be any the less sympathetic to American doctors.

NOTABLE BOOKS.

LES SEROTHERAPIES, PAR L. LANDOUZY.[1]

FOR those desirous of obtaining material for lectures and articles on what is most recent in serum-therapy this book is a treasure-house. To those who fear that serum-therapy will ever entirely displace the older methods of treatment the author says very pertinently in the preliminary lecture:

"Do not imagine that even if serum-therapy and opotherapy should respond more to the demands of medicine that you would not have to care about the old therapeutics which knew so well how in many a pathologic state to bring into action the vis medicatrix naturæ. Do not imagine that the success of serum-therapy will lessen your importance. There will always remain to be cared for, to be treated, to be managed, to be encouraged, only too many unfortunates, some with hereditary affections, with diseases of nutrition, with occupation and alimentary toxemias, the victims of accident, of youthful indiscretion, of dietary errors, of physical or intellectual overwork, the consequences of the struggle for existence, and of the neglect of hygiene inevitable even in our day."

Of course as a good Frenchman he gives Pasteur his proper place as the founder of serum-therapy. All the credit that is due to Pasteur is often not accorded him in America because our medical development of late years has been influenced mainly by German medical thought. Then, too, the slurs cast upon the antirabies injections by the Germans produced an unfortunate prejudice as to Pasteur's other work here; but all that is gone now, even the Germans have been converted and Pasteur is to take the place Landouzy gives him as the bright particular star of modern medical biology.

The review of the deaths attributed to diphtheria serum fills a most interesting chapter. Each is discussed in detail. We note with regard to the most famous one, the Langerhaus child in Berlin, after whose death the father, Virchow's assistant, announced next morning in the papers that it had been *killed by Behring's diphtheria serum*; that though 1300 doses of this identical serum were used in other cases not a single fatality or complication was noted. Landouzy calls special attention to the fact that ozena yields in a majority of cases to injections of diphtheria serum and in the other cases improvement almost invariably follows.

The question of the expectation of life after tracheotomy is an extremely interesting one. Ten years ago Landouzy reviewed the subject in a series of lectures in which he showed that tuberculosis nearly always carried off tracheotomized patients within a comparatively few years after the operation in practically all cases. He now repeats this conclusion and in the light of his riper experience and continued observation on the subject it must carry great weight. He quotes Dr. Simon of Paris, who has passed his life among children and who does not know of a single living adult who had been tracheotomized as a child.

For tetanus Professor Landouzy insists very much on the value of preventive inoculations. When he delivered these lectures the intracerebral injection of tetanic antitoxin had not been thought of. Tetanus antitoxin can now be produced of such marvelous antitoxic value that in all cases that carry with them in the slightest degree the suspicion of infection with tetanus germs he advises the injection of a preventive dose. Tetanus serum is now made that is efficient to one-trillionth; that is, an animal injected with one-trillionth of its weight of the antitoxin can with impunity be given an otherwise absolutely fatal dose of tetanus toxin and will survive without manifesting any symptoms. In human beings the preventive dose would be infinitesimal—a minim or less.

The lectures on antivenomous serum are of more interest to Americans now that our recent acquirements in the tropics and the East are apt to bring our soldiers and colonists more in contact with venomous serpents. The discussion of the subject is complete, the English as well as the French contributions being thoroughly reviewed. The diffusibility of snake-venom and the absolute necessity for rapid action after snake-bites is illustrated by an experiment on a rat. An injection of cobra-

[1] Les Serotherapies. Leçons de Therapeutique et Matiere Medicale professées á la Faculté de Médicine de l'Université de Paris. Par L. Landouzy. Paris: MM. Georges Carré et C. Naud, 1898.

venom is made into the rear third of a rat's tail and one minute later the tail amputated. Death takes place nevertheless from the poison.

An interesting review of a subject not often heard of outside of France is concerned with the serum-therapy of the manifestations produced by the invasion of the colon bacillus of parts outside the intestinal tract. Italian workers have shown that immunity is conferred on animals by certain soluble products of cultures of the bacillus coli. As urinary infection is nearly always caused by the colon bacillus finding its way into the bladder, Albarran and Mosny have tried certain products of the bacillus for therapeutic purposes in these cases and with encouragingly good results.

Landouzy had the opportunity to study Maragliano's serum very carefully in Paris in his own clinic. He thinks it does relieve certain symptoms of the disease, as the fever and sweating that are due to the toxins absorbed from the tubercular foci, but does not think that it influences the tubercular process itself. It is antidotal but not anti-infectious; it is antituberculinous but not antituberculous; antitoxinemic but not antimicrobic, to quote Landouzy's own series of adjectives.

A series of very interesting lectures is devoted to what Landouzy calls artificial serum-therapy, *i.e.*, to the injection of normal salt solution. He insists that this shall be prepared from recently *boiled* distilled water, not from aqua destillata that has been standing for some time. He uses the normal salt-water injections in minimal and maximal doses. Given in from 2-5 c. c. (minimal dose) into the buttocks or directly over the seat of pain he recommends them for their mental effect, in helping to overcome certain bothersome, partly physical, partly psychical symptoms of lipothymiques, *i.e.*, delicate, nervous individuals or convalescents. In maximal doses of a pint and more he considers them extremely efficient in a number of medical as well as surgical emergencies, but this subject is well known.

CORRESPONDENCE.

QUININ IN MALARIAL HEMOGLOBINURIA.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—I send you a volume containing some statistics concerning the use of quinin in malarial hemoglobinuria and a brief article on the pathology of that disease. These have been called forth by the reply to Dr. Hare in the MEDICAL NEWS of January 21, 1899.

I must add my feeble protest to that of Dr. Deffenbaugh to your propagation of a rather fatal therapeutic doctrine, that is largely hereditary in our standard textbooks.

The immediate cause of death in nearly all the cases of malarial hemoglobinuria to which I have had reference, or that have come under my notice, has been "urinary suppression." As this is not a factor in the ordinary malarial manifestations there must be some added element which renders its pathology different, either in kind or in degree, from the other forms.

When this difference has once been clearly defined, when the pathological condition present in a case of acute malarial hemoglobinuria can be put alongside of that in one of malarial quotidian fever, it may then be seen why a remedy that is antidotal in the one case may be lethal in the other, although the underlying cause may be the same in both.

A national therapeusis can arise from a sound pathological foundation only. This we will not have until a scientific clinical study of the question is made here in the South where this fever prevails.

Many lives are sacrificed each year that might be saved and I am glad to see the question of treatment brought so prominently into notice by your journal. The Johns Hopkins school has done so much in this country to advance our knowledge of the malarial parasite and its effects on the human body that it would seem particularly its province to settle the mooted points on this phase of the question. This work can only be done by those trained for this kind of investigation, and I regret that such specialists and malarial hemoglobinuria are not generally found in the same localities. Very truly yours,

BROOKS COLOMB, M.D.

UNION P. O., LOUISIANA, February 27, 1899.

We too shall be sincerely glad if our articles on quinin in malaria attract renewed attention to certain phases of the question and especially to the use of quinin in so-called malarial hemoglobinuria. In setting forth the practical conclusion that quinin should be freely used wherever malaria is clearly present no matter what the complication, we were but following some of the world's best authorities on malaria. When the original article on quinin in malaria was written the idea was to combat a certain feeling of distrust that had recently sprung up with regard to the free use of quinin in the estivo-autumnal type of malaria which has become familiar to us because of the Cuban campaign. This distrust had been fostered by ill-advised protests, editorial and otherwise, in certain medical journals and had already shown its effect by a tendency on the part of certain physicians to give too small doses of quinin in general, and on the part of soldiers and others exposed to malarial infection by a refusal to take quinin as a prophylactic.

As to the so-called malarial hemoglobinuria we are not ourselves convinced of its malarial origin. It is not merely the expression of an intense malarial infection. It occurs very rarely in Italy though pernicious malaria is not uncommon there. In Europe it occurs frequently only in Greece. It occurs in certain parts of Africa but not in others. In our own South there seems reason to think that it is not due to severe malaria alone, but that there is something specific about it, since it is much more frequently reported in certain malarial districts than in others. The subject is well worthy of study. Meantime excellent authorities insist on the free use of quinin in the condition if there are (sometimes there are not) clear symptoms of malaria with it. That quinin is not its original cause is evident since it does not occur in Italy where quinin is probably used with more freedom than any other place in the world. We shall be only too glad to

welcome from workers in Southern fields contributions that will tend to throw light on this interesting and extremely important question—ED.

MORTALITY FROM TYPHOID FEVER IN PHILADELPHIA.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—When I failed to see my letter to you in your issue of March 4th, though you must have received it in ample time to publish it, and I had no acknowledgment of its receipt, I thought—perhaps too hastily—that you did not intend to publish it, and being desirous that the real facts should be known, I took the letter to the editor of the *Philadelphia Medical Journal*, who kindly agreed to insert it in his paper. This is the explanation, which I think is due you, of the letter appearing in both journals at the same time.

The editor of the *Philadelphia Journal* thought with you that my statistics were too ancient, so that I furnished him with statistics of a later date to be placed in a note to my letter. These figures represent the average death-rate of typhoid and malarial fevers per 100,000 persons living for the seven-years period (1890–1896), and are as follows:

	New York.	Brooklyn.	Philadelphia.	Boston.
Typhoid Fever...	19.72	18.48	44.60	32.48
Malarial Fever...	7.87	16.45	3.04	

These statistics show an even lower death-rate from typhoid fever in Philadelphia than I claimed before, a fall from 69.35 in the preceding six years, or a diminution of about 36 per cent., and the decrease would have appeared greater if I had included the deaths from "malarial fever," but I have not done this as you object, somewhat unreasonably as it appears to me, to consider the two causes of death together. On the other hand in the three remaining cities the decrease in typhoid mortality is shown to have been but about 19, 20, and 17 per cent. respectively, or about half as much as in Philadelphia. If these results are held as a measure of the exertions of the several cities against the spread of the disease, I think it must be acknowledged that Philadelphia has done twice as much in the period named as either New York, Brooklyn, or Boston in diminishing its death-rate from typhoid fever.

The reasons for my taking the older statistics in my first letter were that the accepted measures for the prevention of typhoid fever are practically the same now as they were ten years ago and I believe the older figures to be the more reliable, being based upon the population as returned by the United States census, while later figures are subject to the optimism of their compilers with regard to the increase of population, an optimism likely to be exaggerated in the sanguine atmosphere of New York. But I am generous enough not to regret it when I consider the satisfaction you must have felt at being able to get off once more that time-honored joke with reference to the alleged want of progressiveness in Philadelphia which seems so dear to the hearts of "a certain class of" New Yorkers.

I have to find fault with you in your remarks on my letter that you start off again on your curious career of misrepresentation. Though I distinctly said at the beginning that I did not intend to defend the presence of typhoid fever in Philadelphia, which no one deplores more than myself, but simply to expose the pharisaical nature of your attack upon the city, you make that the issue and then proceed to tear to pieces the man of straw you have set up. Surely you must know that is an old, and the most discredited, trick of the pettifogger. I should be ashamed of that, my dear fellow. It would take too long and perhaps be unprofitable to expose all of your misrepresentations, but there is one assertion you make in your editorial, and reiterate in your remarks, so contrary to the facts, that I wish to make an issue of it, and I hope you will meet the question in a manly, straightforward way, and not with amusing persiflage. You say, speaking of the prevalence of typhoid fever in Philadelphia, "matters have grown worse not better in the last fifteen years" and "the last year is the worse of the ten," and you insist upon this in spite of my unchallenged statistics which show a decrease of thirty per cent. in late years. You give no statistics, even "manipulated" ones, and I call upon you for the proof of your assertion. I have no doubt you can accumulate to sustain you as many opinions as there are leaves in Vallombrosa, even one from that eminent medical authority the daily *New York Times*, but these without facts will avail you nothing.

RICHARD A. CLEEMANN, M.D.

PHILADELPHIA, MARCH 12, 1899.

[It seems too bad that a medical man should plunge into a controversy on a medical subject and know so little about it, as our correspondent confesses that he knows about typhoid fever in Philadelphia. He now quotes statistics of more than three years ago and wishes to know our authority for the statement that the last one of the last ten years was the worst of them all as regards the deaths from typhoid fever. Why did he not consult the Philadelphia health reports before putting pen to paper on so important a subject?

In our issue of February 4th our Philadelphia correspondent quotes from the annual report of the Medical Inspector of the Board of Health of Philadelphia the number of cases of typhoid that occurred in Philadelphia during 1898 and the deaths therefrom. There were 4749 cases of typhoid in the city, excluding 1348 cases among soldiers in Philadelphia hospitals, and 639 deaths. But why go back to the statistics of other years to say that Philadelphians, all of them, are criminally negligent of their duties as citizens? During the week ending March 4th, there were **443** cases of typhoid fever in their city, and **49** deaths, and during the week ending March 11th, there were **419** cases, with **39** deaths. During the eleven weeks of the year **1899**, up to March 11th, there were **381** deaths from typhoid. This indicates the existence of almost a pestilence in the city, and yet *nothing, absolutely nothing* is being done to remedy the matter, and physicians are not wanting to attempt to defend this awful state of affairs!—ED.]

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

TEN-WEEKS' RECORD OF THE TYPHOID EPIDEMIC AND AN EPIDEMIC OF CEREBROSPINAL MENINGITIS—MODERN ANATOMY—TYPHOID COMPLICATIONS—RETRODISPLACEMENTS OF THE UTERUS—PERSONAL NOTES—HEALTH STATISTICS.

PHILADELPHIA, March 13, 1899.

THE end of the week brought the total number of cases of typhoid fever reported since January 1st up to *3424* and the total number of deaths for this period, ten weeks, is *360*. During the past week another epidemic has started, one of cerebrospinal meningitis, and thus far, or during last week, 34 cases with 13 deaths have occurred, 5 cases and 5 deaths having been reported on Saturday alone.

A special meeting of the Board of Health has been called for Tuesday, the 14th, for the purpose of discussing the best method of combatting and preventing the spread of "spotted fever" and a memorial has again been presented to the councils urgently requesting immediate action looking to the betterment of our water-supply. Editorials in the press and resolutions from various bodies of citizens seem to have no effect, however, and the merry death-dance goes on.

At a meeting of the Philadelphia County Medical Society, held Wednesday, March 8th, Dr. Edmund W. Holmes read a paper on "Modern Anatomy" which was discussed by Professor Carter of the Central High School, Professor Trotter of Swarthmore College, Dr. Allis, Dr. Forbes, Dr. Mills, Dr. Hewson, Dr. Beattes, and many other men interested in teaching. Dr. Holmes thinks there are three fallacies in medical teaching: large clinics, didactic lectures, and old-fashioned dissecting-rooms. He characterized the medical student of to-day as an investigator and no longer a receptacle for words such as the didactic lecture forces him to be. He believes the didactic lecture should outline the part to be dissected perhaps but believes actual observation should take the place of lectures, that museum specimens should be kept in the dissecting-room and be used, and that the old idea that anatomy can only be learned by dissection by the student is fallacious unless the latter be shown how to dissect and knows what he is dissecting or in other words has some preliminary knowledge of anatomy. Dr. Holmes made a strong plea also for the teaching of histology, embryology, and comparative anatomy in schools preliminary to medicine, thus giving more time in the medical school which with advantage could be used in other ways. He compared the average student who dissects one subject, part by part, to an engineer who has seen one engine taken apart or put together. In conclusion he expressed his belief that the younger men should do the demonstrating and general routine work, thus utilizing didactic lectures as supplements to the course and giving a professor of a branch time for original work and research.

Dr. Forbes followed and said that the "sanctus sanctorum" in the temple of Hippocrates was the dissecting-room, for human anatomy is the basis for all medicine. Comparative anatomy he considers unnecessary and he believes the cause of insufficient anatomical knowledge is to be found in insufficient time for its study and lack of subjects, though the latter trouble has been partly overcome by the Anatomical Act (for the enactment of which Dr. Forbes did so much). The idea Dr. Forbes tries to follow in his teaching is that of having his demonstrators act as tutors to small sections of students and to personally conduct weekly examinations of the students on the cadaver.

Many unusual and interesting features of the present epidemic of typhoid were reported last week, Dr. Joseph Sailer reading a paper on "Typhoid Ulcer in a Meckel's Diverticulum" and Dr. David Riesman one on "Typhoid Ulcers in the Esophagus."

A symposium on "Retrodisplacements of the Uterus" was held by the Obstetrical Society on March 2d. Dr. Wilmer Krusen discussed the etiology and said that of 1000 women applying to the gynecologic department of Jefferson Medical College Hospital, 199 or 19.9 per cent. had displaced uteri. He called attention to the importance of etiology in the treatment. Dr. J. M. Fisher discussed the diagnosis, Dr. F. H. Maier the non-operative, and Drs. C. Norris and Frank Hammond the operative, methods of treatment.

Drs. J. C. Wilson, John H. Musser and A. H. Hulshizer have been appointed by the Philadelphia County Medical Society as a committee to go before the State Legislature to protest against the Antivaccination bill which is to be discussed on the 14th inst.

Charles H. Heustis, recently appointed health officer by Governor Stone, formally succeeded Dr. Benjamin Lee last week.

The total number of deaths occurring in Philadelphia for the week ending March 11th, as reported at the health office was 520, an increase of 56 over those for a corresponding period last year. The total number of new cases of contagious diseases was 501, reported as follows: diphtheria, 50 cases with 10 deaths; scarlet fever, 32 cases with 1 death; typhoid fever, 419 cases with 39 deaths.

OUR LONDON LETTER.

[From Our Special Correspondent.]

MR. SIMS WOODHEAD SUCCEEDS THE LATE PROFESSOR KANTHACK—THE LIFE OF JOHN HUNTER—DEATH OF THOMAS COOKE, THE FAMOUS "COACH" IN ANATOMY AND PHYSIOLOGY—RANDOM NOTES.

LONDON, March 3, 1899.

THE recent medical event of greatest interest was the election of G. Sims Woodhead to the Chair of Pathology in the University of Cambridge, left vacant by the untimely death of Professor Kanthack. Sims Woodhead needs no introduction to the American profession, as his work for years past has attracted wide attention. He was born in 1855 and graduated in medicine at Edinburgh University in 1878. He taught in the University for several years and in 1890 was elected Director of the Research Laboratories of the Conjoint Board of the Colleges of Physicians and Surgeons, which position he still

holds. His duties at Cambridge will be assumed in April and as yet no one has even been mentioned as his probable successor at the Embankment Laboratories.

The Board of Electors at Cambridge is much concerned over a report published in the *Times* from their Montreal correspondent to the effect that Professor Adami had declined the chair just filled. One of them has taken the trouble to write to the paper stating that the board had held no meeting and no offer or even proposition had been made to any one previous to the formal election of Professor Woodhead.

The annual Hunterian oration was delivered a short time ago at the Royal College of Surgeons by the President of the college, Sir William MacCormac. Special interest was given by the presence of the Prince of Wales, in graceful recognition of his indebtedness to the surgical profession for his rapid recovery from his recent accident. H. R. H. is a man of catholic tastes, which includes even medicine, this being the third Hunterian oration which he has listened to, while he actually holds the honorary degree of Fellow of the Royal College of Physicians. The life and career of the father of modern scientific surgery, both English and German, as Billroth cordially acknowledged, was interestingly passed in review. Born in 1728 on a little Scotch farm he came down to London, a raw country lad at the age of twenty, indifferently educated, and in thirty years had made himself not merely the first surgeon but one of the foremost scientists of the world. He gleaned his facts from every department of natural history and even of chemistry and mineralogy and recognized the unity of life and disease and their laws in all forms of organized beings. He was a tireless worker, rising at half past four to dissect till breakfast-time, seeing patients all the morning, attending to hospital work and performing operations all the afternoon, and attending to case-recording and correspondence and working over his results till midnight. No wonder that at thirty-one he broke down and developed lung-trouble, but this only drove his genius into a new field, for he secured a surgeonship in the army and spent four years abroad in active campaigning. This restored his health and enabled him to lay the foundations of his masterpiece "The Blood, Inflammation, and Gunshot Wounds," most of which is sound surgery to-day in spite of our tremendous advances. It is not generally known that Hunter's celebrated ligation-operation for aneurism was first performed upon a stag. A buck with his horns in velvet was caught, thrown, and the artery supplying one of them tied. Two weeks later circulation was re-established and on cutting down upon the artery it was found converted into a fibrous cord. Encouraged by this he operated upon a popliteal aneurism in the human subject a month or so later, with complete success.

Even bad smells have their uses. The abominable sulphurous odor of ordinary coal-gas is so great an advantage in giving prompt warning of leaks or escapes that the Committee of Experts appointed by the Local Government Board to investigate the dangers of water-gas has brought in the curious-sounding recommendation that no gas that has not a well-marked odor be permitted to be laid down in cities. It also advises that no form of water-gas should be used by any company except mixed with coal-gas in a fixed proportion to be specified in the company's permit and tested by inspectors from time to time, no gas supplied during the night to contain more than twelve per cent. of carbon monoxid. As the committee consists of Professors Haldane and Ramsay, its recommendations are about as scientifically authoritive as could be desired.

The specialization of medicine still progresses. At the last meeting of the British Medical Association a Section of Life-Insurance Examiners was held and a number of interesting papers read. Now it is announced that an International Congress of Physicians to Life Assurance Companies will be held at Brussels from September 25 to 30, 1899, to which delegates are expected from all over the world.

A unique character in the English medical world has just passed away. This is Mr. Thomas Cooke, the most celebrated "coach" in anatomy and physiology that London has ever seen. Usually the occupation of professional "crammer" for medical examinations is not regarded as the most elevated, but Mr. Cooke was so thorough in his work and so admirable in his methods that he achieved positive fame thereby. The candidate who came to his school to be prepared for an examination was not set to work on text-books, memory-lists, and "tips," but given a set of bones, a lot of dissected specimens, and a cadaver, or put at a laboratory-table and set to work. He taught by objects, not words, and his fame spread until he had a large school with a number of assistants under him. Probably no better proof could be given of the meritoriousness of his work than the fact that the very examining-body for which he prepared students, the Royal College of Surgeons, recognized his certificates of attendance as satisfactory time-credentials, a recognition not accorded to any other private school of medicine. Curiously enough America can claim a small share in his reputation for he was born in the United States but taken to Paris when a mere boy, educated there and served in several of the hospitals and finally settled in London.

Two curious cases of poisoning have just been reported. In one instance a tradesman was given some strong atropin drops for a keratitis by his physician. A few days later his whole family were prostrated with severe symptoms of atropin poisoning, due to the servant having used the drops aforesaid to flavor a pudding. They were promptly and vigorously treated and all recovered, and now the courts are endeavoring to decide whether the drops were put in accidentally or purposely. (The servant did not eat any of the pudding.) The other was a most infantile attempt by a German cook to drug his employer's family with a view to robbery by putting chloroform in their soup. Perhaps he hoped it might work while they were saying grace. As might have been expected the chloroform revealed itself with great *éclat* the moment the cover was taken off the tureen and no one was a pin the worse—except the cook who had to sleep at the police-station that night.

An excellent step has just been taken by the Local

Government Board with reference to the medical inspection of schools. An order has been issued that no child suffering from any contagious affection of the scalp, skin or eyes shall be admitted to the workhouse (poorhouse) schools of London; that all children shall be examined medically before being admitted to such schools; and that the whole school shall be submitted to a thorough medical examination at least once a month. No doubt this class of schools needs these safeguards badly enough, but they ought to be extended to every school in the country. A weekly or even daily visit of inspection, however brief, by a trained pediatrist and hygienist, who both loves and understands the needs of the young human animal would be of incalculable benefit to our schools.

Another human ostrich has been heard from. An itinerant conjuror, part of whose performance consisted of swallowing pebbles, ranging in size from that of a pigeon's egg down, was brought into Peterborough Infirmary in great distress. Whether he rattled audibly on being shaken is not stated, but an appropriate course of laxatives brought away more than sixty small stones weighing altogether nearly two pounds. The man stated that he had been swallowing pebbles for years and this was the first inconvenience he had ever suffered. Truly the human stomach is patient. Pebbles, however, would seem to be a cumulative poison, like lead and digitalis.

Our unpleasant suspicion of last week in regard to the prospects for revaccination legislation proves to be justified. Mr. Balfour announced in the House a few evenings ago, in answer to a question, that the Government had no intention of presenting any bill dealing with vaccination this session. The Committee on Bills of the British Medical Association will probably introduce a bill but there is little hope of its being reached this sesssion.

Jane White, sentenced to death for the "constructive murder" of Alice Hearsh by instrumental abortion, has been reprieved, but the final form of her sentence has not yet been announced. Both the Home Secretary and the Attorney-General have been fairly bombarded with questions as to how long this ridiculous farce of "constructive-murder" sentences, which are never intended to be carried out, is to continue. Both of them have assured the House that steps will be quickly taken to remedy this legal defect.

The influenza epidemic from which London, in common with the cities of the Continent, is suffering is rapidly increasing. At a recent function nearly one-third of the expected guests sent their regrets on account of it. So far the disease is not of a very severe type but fifty deaths were attributed to it in London last week.

Another of the curiosities of Chinese medicine has recently been unearthed. This is a powder made of salted and dried hen's brains, which is regarded as a sovereign remedy for neurasthenia and debility. This has been in use for several centuries in the Flowery Kingdom and we have only just discovered cerebrine and cardeine!

Contagious Diseases, New York City.—For the week ending March 11th, from tuberculosis, 178 cases, 202 deaths; typhoid fever, 17 cases, 6 deaths; measles, 280, 15 deaths.

LAPAROTOMY FOR HEMORRHAGE—TONSILLITIS AND RHEUMATISM—GAS IN TUBERCULAR ABSCESSES—ENLARGEMENT OF THE SPLEEN IN MUMPS—ON THE CHOICE OF AN ANESTHETIC—CONGENITAL PYLORIC HYPERTROPHY—DEFINITE MIXTURES OF NITROUS GAS AND AIR OR OXYGEN—TREATMENT OF OZENA BY CUPRIC ELECTROLYSIS—POPULARITY OF THE PESSARY NOT WANING—RECOMMENDATIONS TO LIMIT THE SPREAD OF TUBERCULOSIS.

AT the Clinical Society, January 27th, HUTCHINSON read notes of cases in which he had performed abdominal section without external evidence of injury. A man, aged thirty-two years, was run over and became collapsed. There was abdominal tenderness and distention due to the presence of fluid. On the following day these symptoms were more marked and his temperature was 102° F. Upon opening the abdomen Hutchinson found it full of blood which he removed. No cause for the hemorrhage could be found and the wound was closed. The next day there was again some blood in the abdomen but the patient recovered. He thought that blood in such cases could give rise to trouble and ought to be removed. In a second case there were symptoms of intestinal obstruction in a pregnant woman. Nothing was found in the abdomen except two pints of pale, odorless, straw-colored fluid. The intestines were slightly congested. The origin of the fluid was not ascertained and the abdomen was closed. The following day the patient aborted and soon after died. A large quantity of the same fluid was found at autopsy and a search revealed a minute perforation of the bladder which admitted urine into the peritoneal cavity through an opening an inch above the peritoneal reflection. The perforation was presumably due to an attempt to produce abortion.

LANGTON thought that the abdomen should be opened in cases of concealed hemorrhage, not merely on account of the possible danger from the contained blood, but to protect the patient from the bad effects of internal injury.

ABRAHAM read a paper on rheumatic tonsillitis, basing his remarks upon a large number of cases of chorea, rheumatism, and cardiac disease both in adults and children observed in the last three years. Clinically five varieties of rheumatic throat affection may be distinguished: (1) Faucial erythema which often ushers in an attack of rheumatism. (2) Follicular tonsillitis. (3) Quinsy. No pathologic distinction can be made between this form and the preceding although it is noticed that when patients have repeated attacks they are almost always of the same form, alternations from one variety to the other being rare. (4) An abortive form described by Singer, in which the joint and muscular pains are vague. (5) Chronic rheumatic tonsillitis probably of gouty nature.

One-half of the cases of chorea, two-thirds of those of heart disease, and almost one-half of those of acute rheumatism gave a definite history of throat disease. Bacteriologic examination of the tonsils revealed the constant presence of streptococci and staphylococci. Sim-

ilar organisms were found in urine drawn with every precaution from the bladder. The probability of infection through the tonsils, therefore, is very strong. Many believe that the rheumatic patient is poisoned by the attenuated virus of a germ, which, when fully active, leads to pyemia. The following conclusions were offered: (1) The more common varieties of rheumatic sore-throat fall into two main categories—faucial erythema and tonsillitis proper. (2) Faucial erythema is most common in adults, and rheumatic tonsillitis in children in whom it usually assumes the follicular type, quinsy being more frequent in older subjects. (3) Faucial erythema is an initial manifestation of acute rheumatism and tonsillitis may be the actual primary lesion. (4) Many cases are now definitely on record in which endocarditis has followed a non-scarlatinal tonsillitis unaccompanied by joint pain. In numerous other instances the tonsillitis has immediately preceded an attack of arthritis or of chorea. (5) The presence of the same micro-organisms in the tonsils, joints, blood, and urine is evidence in favor of the participation of pyogenic cocci in the etiology of rheumatism.

CARR suggested that an ordinary tonsillitis might attack a rheumatic as well as any other patient. In some of the cases mentioned there was an interval of years between the sore throat and the development of rheumatism. He had not been able to convince himself that antirheumatic remedies have any curative action upon tonsillitis.

At the meeting of February 10th, SPENCER described an unusual case of tubercular cavities in the lungs, giving rise to gaseous metastatic abscesses in the right pleura, the back, and the upper part of the left thigh. The abscess in the thigh was opened first and was found to contain gas and pus having a fecal odor. It extended through the greater sacrosciatic notch into the pelvis but not to the near neighborhood of the bowel. Later the patient developed an acute effusion into the right pleural cavity, and the fluid aspirated had a fecal odor and contained pus-cells. About four months later the patient died. Both lungs were filled with tubercles and there was one large cavity. There was also extensive caries of the ribs on both sides. Colon bacilli were found in the pus.

At the Harveian Society, February 2d, EWART showed a boy who had just recovered from a mild attack of mumps on the left side. The only complication was an enlargement of the spleen which persisted for several days and gradually subsided as the parotid gland returned to its normal rize. There was no fever, nor symptoms referable to the spleen. At its maximum the spleen measured 6.5 inches horizontally and 5 inches vertically. The blood was stained for micro-organisms with negative results.

A discussion on the choice of an anesthetic at the Society of Anesthetists, January 20th, showed that the members were as far as ever from an agreement as to the relative merits of ether and chloroform under different circumstances. Whatever anesthetic is chosen should not be given hurriedly, nor by an inexperienced person. JONES said that in every case the surgeon should place the facts in hand before the anesthetist and allow him to make the choice of the anesthetic.

At the Pathological Society, February 7th, STILL reported three cases of congenital hypertrophy of the pylorus, all occurring in boys, with death in twelve to fifteen weeks after birth. The symptoms were vomiting, constipation, and increased gastric peristalsis which could be seen through the abdominal wall. In all three patients the thickened pylorus was palpable before death. In all three the thickening was chiefly muscular, and the lumen was normally patent. The lumen of the normal pylorus at birth often measures only 3.5 to 4 mm. (⅛ to 1/6 of an inch), so that one must speak with caution of slight degrees of hypertrophy. He considered the condition a congenital one, but that disturbance of function was the exciting cause. There is every reason to believe that some patients recover.

CAUTLEY, who showed specimens of the same trouble from three infants much younger than those reported by Still, expressed the opinion that the trouble was purely an intra-uterine one.

At the Royal Medical and Chirurgical Society, February 14th, HEWITT read a paper on the effects upon man of definite mixtures of nitrous oxid and air, and nitrous oxid and oxygen. Pure nitrous oxid causes deep stertorous breathing, cyanosis, and anoxemic convulsions. These may be avoided by mixing oxygen or air with the gas, but there is no fixed proportion which will best answer for all patients. The best anesthesia is obtained by commencing with a mixture of gas with two per cent. of oxygen, and increasing the latter gradually until eight or ten per cent. is employed. The next best results to these are obtained with fixed mixtures of gas and oxygen, 5, 6, or 7 per cent. for males; 7, 8, or 9 per cent. for women and children. Next after these results gas and air, 14 to 18 per cent. of the latter for men, and 18 to 22 per cent. for women and children have been proved to be best.

At the Edinburgh Medico-Chirurgical Society, February 1st, MCBRIDE described the mode of treatment of ozena by cupric electrolysis. Four of eight unselected subjects were cured and remained so for eighteen months. The others had been recently treated. Cocain was employed. With a current of 10 milliamperes a copper needle was attached to the positive pole, and inserted into the inferior or middle turbinate bone while the platinum or steel needle was inserted into the septum. There was little or no pain at the time or afterward. The good effects might be due to the copper as well as to the electricity.

TURNER said that the interest in the matter lies in the rationale of the treatment. It is not bactericidal, as the same organisms are found after treatment as before. Moreover, with treatment on one side only, both sides of the nostrils improve. Perhaps the benefit comes through an improved trophic condition. In a similar manner the serum treatment might stimulate secretion and thus cause the crusts to be thrown off.

At the Edinburgh Obstetrical Society, February 8th, BALLYNTINE read a paper on the position of the pessary in gynecologic practice. From the instrument-makers he learned that pessaries are purchased more and more, but that the demand is now practically for only two patterns,

the Smith modification of the Hodge, and the simple rubber ring containing a watch spring. The demand for curettes, especially Martin's, has been remarkable, while the popularity of caustic holders and instruments of that type has decreased.

At the Liverpool Medical Institution, February 9th, the tuberculosis committee presented a report, which was adopted, recommending the following measures: The diffusion of information concerning the disease; the arrest of tuberculosis by diminishing the sources of infection; the provision of sanatoria and special hospitals; the voluntary notification of infected houses and the disinfection of the same by the health authorities. The committee was of the opinion that the public was not yet ready for compulsory notification. Great satisfaction was expressed at the enormous decrease in tuberculosis within the past generation, and confidence was shown that with a reasonable degree of attention to the needless spread of the disease, the decrease could be continued at even a faster rate than in the past.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.—SECTION ON GENERAL MEDICINE.

Regular Meeting, Held Tuesday, February 21, 1899.

The Chairman, Dr. Louis Faugeres Bishop, announced the subject of the evening as

RABIES.

Dr. Follen Cabot demonstrated a guinea-pig and a rabbit which had been inoculated with the disease. This was the sixth day after the inoculation, and both animals showed signs of the disease, but it was the dumb or paralytic form, not the violent one. Both animals would continue in their quietude very probably until death, though sometimes there was, even in the midst of the paralytic form, sudden violent outbursts. Dr. Cabot then read a paper, entitled

RABIES AND ITS PREVENTIVE TREATMENT; AN ANALYSIS OF CASES,

which will be found on page 321.

A paper, entitled

CLINICAL CASES OF HYDROPHOBIA IN ANIMALS,

by Dr. S. R. Johnson and Professor H. D. Gill, owing to their unavoidable absence, was read by the secretary. They described the symptoms of rabies, especially in dogs. The animals usually become markedly changed in disposition. They become noticeably glum, moody, and shun the light and all companionship, or they become restless and snappy. There is a lurid glare in the eye even of animals quiet hitherto, that is very characteristic. There is a change in the animal's bark easily detected by those familiar with it. Often it becomes metallic; at times, again, is a low howl that is kept up persistently. One dog recently had been operated on for tumor six months before its attack, and had been known as an extremely quiet and patient animal. During its attack it restlessly paced the cage, biting at the bars, barking in a metallic, brassy tone almost unceasingly, never letting up in its activity. In this case the New York Board of Health had decided by inoculation experiments on other animals that true rabies was present.

In another dog the first symptoms had been a dazed look, a tendency to tear things never before noted; it had ruined a lot of lace curtains, and was copiously dribbling from the mouth. When put in a dark cellar by its owner it had gotten worse, and on being brought to the veterinary hospital it had immediately been caged. In the cage it bit through and through its own foot. This also proved on inoculation to be true rabies.

A third animal was excited and restless, and bayed like a hound, quite differently from its usual bark. This change of voice, so to say, was, as is often the case, the first suspicious sign. Then came increased nervousness and restlessness, followed by refusal to take water. These symptoms were followed by a violent stage almost characteristic of rabies.

Discussion.

Dr. R. J. Wilson spoke of the necessity and also the possibility of prophylaxis for rabies. Much has been accomplished in this matter in Paris, so that practically there has been no epidemic of cases there in recent years. If we had adequate dog laws rigidly enforced, as in Germany, it is very probable that we could extirpate the disease in America for some time, at least until the importation of fresh infective material. At present the plain duty seems to be to isolate Staten Island at least for some time, *i. e.*, not permit its dogs to wander out or permit the bringing in of dogs. There have been undoubtedly a series of cases on the island of persons having been bitten by rabid animals.

Dr. Maurice Asher of Newark, N. J., detailed his own experience with a pet dog that bit himself and several members of his family, and was proved later to be rabid. The first symptom of the dog's disorder was restlessness and a distinct, easily noticeable change in its bark. The bark was at times short, sharp, and metallic; at other times a long, drawn-out howl. It did not sleep for three nights, refused the usual food and drink, swallowed other small objects, and was noticed to eat a great deal of snow. Of its own accord it did not bite, but had bitten four people when annoyed by their commands or when they attempted to do something for it that the animal misunderstood. It developed a mania for tearing things, carpets, curtains, table-cloths, etc. Inoculation of parts of its medulla into other animals after it had been killed by chloroform proved that it had rabies. During its irritable stage it had bitten two other dogs whose owners or places of residence Dr. Asher does not know.

All the patients bitten by the animal took the Pasteur preventive treatment, and Dr. Asher described his feelings during the time. The injections are painful directly proportionate to the amount of liquid injected. The local pain is quite acute for some minutes. All in Dr. Asher's household noticed that though their appetite and sleep was not disturbed, they were much more irritable during the time of the injections than they had been before. No

local reactions followed at the site of injection except a passing induration scarce worth noting.

DR. DOUGLASS of Morristown, N. J., next described a case of hydrophobia that occurred recently in his practice. The patient, a farmer, was bitten by his own dog, and the animal was killed. He did not believe in hydrophobia, and took no precautions. After about five weeks he began to develop certain suspicious difficulty in swallowing, and an impending sense of evil came over him. After a few days he could not drink, and attempts to swallow were followed by spasm of the constrictor muscles and other muscles of deglutition. Then respiration was disturbed by spasmodic conditions. At first Dr. Douglass thought he had to deal with a case of lyssophobia, an exaggerated fear of hydrophobia that sometimes leads in people who have been exposed by animal bites to infection with rabies, to nervous symptoms that simulate true hydrophobia. But the symptoms proved steadily progressive and spasms became more general. Finally paralytic symptoms supervened, and after two days of paraplegia death occurred from heart failure. The autopsy revealed congestion in the cortex in the pons and in the floor of the fourth ventricle, also in the medulla, and in the membranes of the cord. Suspicious conditions, but not conclusive. A portion of the medulla inoculated into an animal produced true rabies.

DR. FROTHINGHAM of Boston, Pathologist to the Massachusetts State Cattle Commission, said that he has been for a long time a believer in the existence of rabies in this country in animals, and in its communicability and actual communication to man. His records show 32 cases of suspected rabies examined, 21 of which gave positive evidence of the disease. As he sees it at the laboratories of the Massachusetts Cattle Commission it is usually in the paralytic form. There are no typical post-mortem lesions of the disease as yet known. The only absolutely certain means of recognizing the disease is by the inoculation of a portion of the medulla of the suspected animal into another animal and waiting the result.

It must be remembered that there may be some other pathological condition present in an animal and yet rabies exist too. The other affection may be sufficient of itself to cause death and yet that event be precipitated by infection with rabies. Worms in the hearts of dogs sometimes simulate the symptoms of rabies though they may remain entirely latent for years.

Foreign bodies in the intestinal tract, tumors of the brain, certain parasites that gather in the external ear, may produce symptoms that will deceive a trained veterinarian. Inoculation is the only absolutely sure method of recognizing the disease; post-mortem conditions like perivascular infiltration of the substance of the brain and cord usually are found in rabies but they may be caused by any toxic condition.

The prophylaxis of rabies requires the enforcement of strict license laws for dogs. Laws that will make identification easily possible wherever the animal may be found. Suspected districts should be quarantined for three months, all strange or unclaimed animals gotten rid of, and all other animals muzzled for that length of time. If this could be done effectively, in a year we would be rid of hydrophobia in this country completely.

DR. W. H. PARK thought that the assurance that we had hydrophobia in this country would lead to proper precautions when the danger was understood. The Society for the Prevention of Cruelty to Animals had done something most inadvisable in falsely spreading the information that rabies did not exist on Staten Island. This fostering of doubt led to the failure to enforce even the already existing laws and so permitted the spread of the disease.

DR. HUDDLESTON said that the action of the Society for the Prevention of Cruelty to Animals in refusing to allow portions of the medulla to be used for inoculations seemed to him most inhuman. The mental suffering of three human beings for months because of the uncertainty had been weighed against the suffering of an animal or two for a few days and the animals' rights considered the better. He asked Dr. Cabot for the names of prominent medical men who acknowledged the existence of hydrophobia in America.

Dr. Cabot said that all the prominent pathologists to whom he had written in the matter had assured him of their certainty of its existence here, and a number of clinicians who had had experience with it did likewise. All the names he could not recall, but the list included such men as Welch, Councilman, Osler, Prudden, and other leaders of medical thought.

REVIEWS.

URIC ACID AS A FACTOR IN THE CAUSATION OF DISEASE. By ALEXANDER HAIG, M.A., M.D., F.R.C.P. Fourth edition. Philadelphia: P. Blakiston's Son & Co., 1898.

A FOURTH edition of Haig's "Uric Acid as a Factor in the Causation of Disease" was issued by the publishers twenty months after the appearance of the third edition. This of itself is proof of the great interest taken in the study of uric acid.

There are fashions in pathology as well as in millinery. The history of medicine is replete with examples of the almost universal interest of the profession in one particular subject of investigation to the exclusion of others, and of great and rapid advancement in the knowledge of the subject for the time popular.

To those acquainted with the work and the style of Haig little need be said of the fourth edition. It is a larger book. It is fuller of the data upon which he bases his conclusions. The theory is the same, and the method of presenting it is the same. To the reader there is a certain charm in the familiarity and frankness of the author which is irresistible. He is dogmatic, but he gives one all the arguments upon which he has based his dogma, and he does so in a way certainly most unconventional. The book is divided into chapters, but the first part of it need not have been, so far as the nature of the discussion is concerned. His "laws" or conclusions are given early, and appear and reappear with such frequency that there is no mistaking his meaning. That he assigns

to uric acid a most exalted influence over the destinies of man is exemplified in his new answer to that chestnutty question: "Is life worth living?" "That depends on uric acid!" he says, on page 249, and evidently misses entirely the humor of our own Holmes' answer, "That depends on the liver," for he discusses this most seriously.

That he has elucidated a pathologic law capable of almost universal application is inferred from the passage on page 142: "If my premises are good, and my deductions sound, and if uric acid influences the circulation to the extent which I have thus been led to believe that it does, it follows that uric acid really dominates the function, nutrition, and structure of the human body to an extent which has never yet been dreamed of in our philosophy, and in place of affecting the structure of a few comparatively insignificant fibrous tissues in which it is found after death, it may really direct the development, life history, and final decay and dissolution of every tissue from the most important nerve-centers and the most active glands, to the matrix of the nails and the structure of the skin and hair."

From beginning to end he is an advocate of a diet "uric-acid free," as he calls it, to counteract the effect of the ills already wrought. This "uric-acid free" diet is a diet that excludes all flesh and fish, and things that contain them or their extractives, tea, coffee, cocoa, and chocolate, because of the similarity of the alkaloids of these substances to the chemic formula for uric acid, and all acids, including beers and wines. In his own case he excludes also eggs, because he has found that, while he can not prove that they contain uric acid, he can prove that his own output of uric acid is increased when eggs are used as an article of diet. He obtains his supply of nitrogenous material from milk and cheese, in addition to ordinary vegetables and bread-stuffs.

As an eliminant of uric acid from the blood, he has this to say of lithia (page 82). "Lithia, as I have pointed out elsewhere, though said to be a beautiful solvent of uric acid in a test-tube, yet when given to the human subject by the mouth never reaches the uric acid at all, because it at once forms an insoluble compound with the phosphate of soda in the blood, thus removing from that fluid one of the natural solvents of uric acid, and diminishing its power of holding uric acid in solution." Those who have used lithia freely have found clinically that the results were not commensurate with the theoretical reputation of the drug, and that in efficient doses it is the least agreeable to the stomach of all the alkalies.

Haig's book is not a model of lucid English, of precision in the use of words, or of a scientific and orderly presentation of the subject. But it is a mine of information, and, taken at his own estimate, as a contribution to the study of this most important subject it is of great value, and should be most carefully studied by every physician.

Skiagraphic Atlas, showing the development of the bones of the wrist and hand. By John Poland, F.R.C.S. London: Smith, Elder & Co. New York: G. P. Putnam's Sons, 1898.

This atlas contains the admirable Roentgen pictures of the wrist and hand, at each year from the first to the seventeenth, taken from the author's larger work on "Traumatic Separation of the Epiphyses." A brief account of the anatomy and development of the bones of the forearm and hand is added to the descriptive notes.

Atlas of Syphilis and the Venereal Diseases, including a brief treatise on the pathology and treatment. By Professor Dr. Franz Mracek of Vienna. Authorized translation from the German. Edited by L. Bolton Bangs, M.D., Consulting Surgeon to St. Luke's Hospital, and the City Hospital, New York. Philadelphia: W. B. Saunders, 1898.

This is one of the best volumes in Lehmann's well-known series. It is far above many of the more pretentious atlases that have from time to time appeared. The plates, of which there are 71, are admirable, the coloring leaving nothing to be desired. They show all the ordinary phases of syphilitic manifestations, and of the chancroid, and also include some of the more unusual conditions, which will be specially valuable to those removed from clinical centers. Appended to the plates is a short treatise on syphilis, chancroid, and gonorrhea. For its size, this is remarkably full and accurate. The translation has been well done. We can object only to the too close imitation, in places, of the German, especially in the nomenclature of some of the lesions.

A Text-Book of Physiological Chemistry. By Olaf Hammersten. Authorized translation from the third German edition. By John A. Mandel, Professor of Inorganic Chemistry and Physics, and Adjunct Professor of Physiological Chemistry in the University and Bellevue Hospital Medical College. New York: John Wiley & Sons, 1898.

The author in his introduction bases the forces going on in the syntheses accomplished by the plant on the *vis viva* of the sun, this force being transformed "into the potential energy or chemical tension" of the substances thus produced. We find in these few words a correlation of the laws and phenomena of physics and chemistry, which enter so closely into the problems of both plant and animal life. Viewed from these broad standpoints, the processes going on in the animal being, both normal and pathological, present to us a different aspect, and their analysis in terms of general science is more comprehensive to the investigator. The admirable work of Hammersten has, as in the first edition of this work, been translated in a most painstaking manner, following the author's text and arrangement, as in the original work.

Chapter I. deals with the new developments in this science, and gives us a *résumé* of the researches along these lines during the past few years. In Chapter II. the author classifies the proteids into three large groups, simple and compound proteids and albuminoids, a most simple and admirable classification, each group of which is distinct from the other. Not too much can be said of this work, the two examples noted being only a sample of the value of the same.

This book is more than a text-book as the name implies. As a reference book, both on account of its wide

scope and the carefully selected authorities from which its facts are gleaned, it should be acceptable to all advanced workers in this field. An excellent index covering forty-pages further enhances its value.

A MANUAL OF PHYSIOLOGY, WITH PRACTICAL EXERCISES. By G. N. STEWART, M.A., D.Sc., M.D., Edinburgh, Professor of Physiology in the Western Reserve University. Third edition. Philadelphia: W. B. Saunders, 1898.

THIS new edition of Professor Stewart's Physiology contains considerable new material, and several new and very excellent plates and illustrations. The book is arranged especially as a laboratory guide, for which the practical exercises are intended. Nevertheless the text loses none of its value as a reference work, which, indeed, the exercises themselves enhance.

The chapter on metabolism, nutrition, and dietetics is up to date, and the physiology of the nervous system is interestingly expounded. The practical exercises, chemic, physical, microscopic, and anatomic, are arranged with great care and in great detail, and follow the order of the text, chapter for chapter.

THE LECTURES OF AURELIO BIANCHI ON THE PHONENDOSCOPE AND ITS PRACTICAL APPLICATION, Together with Special Articles by FELIX REGNAULT, M.D., and M. ANASTASIADES, M.D., and translated by A. GEORGE BAKER, A.M., M.D. Philadelphia: George P. Pilling & Son, 1898.

THE publication of these translations comes too late to attract but limited attention. The phonendoscope has been already thoroughly studied in America, and, for the most part abandoned as an overestimated instrument. Those, however, who are interested in the claims and demonstrations of Bianchi will find them in this book, freely illustrated by photograph, diagram, and text.

NURSING: ITS PRINCIPLES AND PRACTICE. By ISABEL ADAMS HAMPTON, late Superintendent of Nurses and Principal of the Training-School for Nurses, Johns Hopkins Hospital. Revised Edition. Illustrated. Philadelphia: W. B. Saunders, 1898.

WE have always held the belief that the nurses in our training-schools received, relatively, too little practical and too much theoretical instruction. A perusal of this work confirms this impression. The trained nurse does not need to know the signs and symptoms of pregnancy nor the differential diagnosis between the acute infectious diseases, as they are outlined in this work; she need not know anything of bacteriology or of the properties of formalin or comol. This information is simply a burden to her mind to the exclusion, sometimes, of the proper way of placing a patient in Sims' position or of properly giving a hypodermic injection. This is not only our own impression, but the burden of these statements has been repeatedly stated to us by graduate nurses who appreciate their lack of practical experience in the small details of their practice.

But, if the authoress has committed a sin in this regard, it is not fair to hold her responsible for a system which regards the nurse as a semidoctor, or, at least, as a pseudo-doctor. She has given, down to the minutest detail, all that a well-trained nurse should know. Her language is clear, concise, and pointed, and it is earnestly to be hoped that every nurse, in or out of hospital, may read and thoroughly assimilate the contents of this book. They will certainly be better practical nurses for knowing and practising much that is contained within its covers.

THERAPEUTIC HINTS.

Treatment of Diphtheria of the Nose and Throat.—In outlying districts where antitoxin is not obtainable and simple irrigation may be impracticable, local antiseptic measures become imperative. A combination of remedies is recommended by ENGLAND who, under such circumstances, has employed the following with excellent results:
